Mani himself composed a large number of works and epistles, which were in great part still known to the Mohammedan historians, but are now lost. The later heads of the Manichæan churches also wrote religious treatises, so that the ancient Manichæan literature must have been very extensive. According to the *Fihrist*, Mani made use of the Persian and Syriac languages; but, like the Oriental Marcionites before him, he invented an alphabet of his own, which the *Fihrist* has handed down to us. In this alphabet the sacred books of the Manichæans were written even at a later period. The *Fihrist* reckons seven principal works of Mani, six being in the Syriac and one in the Persian language; regarding some of these we also have information in Epiphanius, Augustine, Titus of Bostra, and Photius, as well as in the formula of abjuration (Cotelerius, *PP. Apost. Opp.*, i. 543) and in the *Acta Archelai*. They are (1) *The Book of Secrets* (see *Acta Archel.*), containing discussions bearing on the Christian sects spread throughout the East, especially the Marcionites and Bardesanites, and dealing also with their conception of the Old and New Testaments; (2) *The Book of the Giants* (Demons?); (3) *The Book of Precepts for Hearers* (probably identical with the *Epistola Fundamenti* of Augustine, and with the *Book of Chapters* of Epiphanius and the *Acta Archelai*; this was the most widely spread and most popular Manichæan work, having been translated into Greek and Latin; it contained a short summary of all the doctrines of fundamental authority); (4) *The Book Sháhpúrakán* (Flügel was unable to explain this name; according to Kessler it signifies "epistle to King Sapor"; the treatise was of an eschatological character); (5) *The Book of Quickening* (Kessler identifies this work with the "Thesaurus [vitæ]" of the *Acta Archelai*, Epiphanius, Photius, and Augustine, and if this be correct, it also must have been in use among the Latin Manichæans); (6) *The Book πραγματεία* (of unknown contents); (7) a book in the Persian language, the title of which is not given in our present text of the *Fihrist*, but

[1] The name has not as yet been explained, nor is it even known whether it be of Persian or Semitic origin.

which is in all probability identical with the "holy gospel" of the Manichæans (mentioned in the *Acta Archel.* and many other authorities). It was this work which the Manichæans set up in opposition to the Gospels. Besides these principal works, Mani also wrote a large number of smaller treatises and epistles. The practice of writing epistles was continued by his successors. These Manichæan dissertations also became known in the Græco-Roman empire, and existed in collections.[1] There also existed a Manichæan book of memorabilia, and of prayers, in Greek, as well as many others,[2] all of which were destroyed by the Christian bishops acting in conjunction with the authorities. A Manichæan epistle, addressed to one Marcellus, has, however, been preserved for us in the *Acta Archelai*.[3]

Manichæan system.

Though the leading features of Manichæan doctrine can be exhibited clearly even at the present day, and though it is undoubted that Mani himself drew up a complete system, many details are nevertheless uncertain, since they are differently described in different sources, and it often remains doubtful which of the accounts that have been transmitted to us represents the original teaching of the founder.

The Manichæan system is one of consistent, uncompromising dualism, in the form of a fantastic philosophy of nature. The physical and the ethical are not distinguished, and in this respect the character of the system is thoroughly materialistic; for when Mani coordinates good with light, and evil with darkness, this is no mere figure of speech, but light is actually the only good, and darkness the only evil. From this it follows that religious knowledge can be nothing else than the knowledge of nature and her elements, and that redemption can only consist in a physical process of freeing the element of light from the darkness. Under such circumstances ethics becomes a doctrine of abstinence in regard to all elements which have their source within the sphere of darkness.

The self-contradictory character of the present world forms the point of departure for Mani's speculations. This contradiction presents itself to his mind primarily as elemental, and only in the second instance as ethical, inasmuch as he considers the sensual nature of man to be the outflow of the evil elements in nature. From the contradictory character of the world he concludes the existence of two beings, originally quite separate from each other—light and darkness. Each is to be thought of according to the analogy of a kingdom. Light presents itself to us as the good primal spirit (God, radiant with the ten [twelve] virtues of love, faith, fidelity, high-mindedness, wisdom, meekness, knowledge, understanding, mystery, and insight), and then further as the heavens of light and the earth of light, with their guardians the glorious æons. Darkness is likewise a spiritual kingdom (more correctly, it also is conceived of as a spiritual and feminine personification), but it has no "God" at its head. It embraces an "earth of darkness." As the earth of light has five tokens (the mild zephyr, cooling wind, bright light, quickening fire, and clear water), so has the earth of darkness also five (mist, heat, the sirocco, darkness, and vapour). Satan with his demons was born from the kingdom of darkness. These two kingdoms stood opposed to each other from all eternity, touching each other on one side, but remaining unmingled. Then Satan began to rage, and made an incursion into the kingdom of light, into the earth of light. The God of light, with his syzygy, "the spirit of his right hand," now begot the primal man, and sent him, equipped with the five pure elements, to fight against Satan. But the latter proved himself the stronger, and the primal man was for a moment vanquished. And, although the God of light himself now took to the field, and with the help of new æons (the spirit of life, &c.), inflicted total defeat upon Satan, and set the primal man free, the latter had already been robbed of part of his light by the darkness, and the five dark elements had already mingled themselves with the generations of light. It only remained now for the primal man to descend into the abyss, and prevent the further increase of the generations of darkness by cutting off their roots; but he could not immediately separate again the elements that had once mingled. These mixed elements are the elements of the present visible world, which was formed from them at the command of the God of light. The forming of the world is in itself the beginning of the deliverance of the imprisoned elements of light. The world is represented as an orderly structure of various heavens and various earths, which is borne and supported by the æons, the angels of light. It possesses in the sun and moon, which are in their nature almost quite pure, large reservoirs, in which the portions of light that have been rescued are stored up. In the sun dwells the primal man himself, as well as the glorious spirits which carry on the work of redemption; in the moon the mother of life is enthroned. The twelve constellations of the zodiac form an ingenious machine, a great wheel with buckets, which pour into the sun and moon, those shining ships that sail continually through space, the portions of light set free from the world. Here they are purified anew, and attain finally to the kingdom of pure light and to God Himself. The later Western Manichæans termed those portions of light which are scattered throughout the world—in its elements and organisms—awaiting their deliverance, the *Jesus patibilis*.

It is a significant mark of the materialistic and inhuman character of the system that, while the formation of the world is considered as a work of the good spirits, the creation of man is referred to the princes of darkness. The first man Adam was engendered by Satan in conjunction with "sin," "cupidity," "desire." But the spirit of darkness drove into him all the portions of light he had stolen, in order to be able to dominate them the more securely. Hence Adam is a discordant being, created in the image of Satan, but carrying within him the stronger spark of light. Eve is given him by Satan as his companion. She is seductive sensuousness, though also having in her a small spark of light. But if the first human beings thus stood entirely under the dominion of the devil, the glorious spirits took them under their care from the very outset, sending æons down to them (including Jesus), who instructed them regarding their nature, and in particular warned Adam against sensuality. But this first man fell under the temptation of sexual desire. Cain and Abel indeed are not sons of Adam, but of Satan and Eve; Seth, however, who is full of light, is the offspring of Adam by Eve. Thus did mankind come into existence, its various members possessing very different shares of light, but the men having uniformly a larger measure of it than the women. In the course of history the demons sought to bind men to themselves by means of sensuality, error, and false religions (among which is to be reckoned above all

[1] A βιβλίον ἐπιστολῶν is spoken of in the formula of abjuration, and an *Epistola ad virginem Menoch* by Augustine. Fabricius has collected the "Greek fragments of Manichæan Epistles" in his *Bibliotheca Græca* (vii. p. 311 *sq.*).

[2] The *Canticum amatorium* is cited by Augustine.

[3] Zittwitz assumes that this epistle was in its original form of much larger extent, and that the author of the *Acts* took out of it the matter for the speeches which he makes Mani deliver during his disputation with Bishop Archelaus. The same scholar traces back the account by Turbo in the *Acts*, and the historical data given in the fourth section, to the writings of Turbo, a Mesopotamian, who is assumed to have been a Manichæan renegade and a Christian. But as to this difference of opinion is at least allowable.

the religion of Moses and the prophets), while the spirits of light carried on their process of distillation with the view of gaining the pure light which exists in the world. But these good spirits can only save men by imparting to them the true *gnosis* concerning nature and her forces, and by calling them away from the service of darkness and sensuality. To this end prophets, preachers of true knowledge, have been sent into the world. Mani, following the example of the gnostic Jewish Christians, appears to have held Adam, Noah, Abraham (perhaps Zoroaster and Buddha) to be such prophets. Probably Jesus was also accounted a prophet who had descended from the world of light,—not, however, the historical Jesus, the devilish Messiah of the Jews, but a contemporaneous phantom Jesus, who neither suffered nor died (*Jesus impatibilis*). According to the teaching of some Manichæans, it was the primal man who disseminated the true gnosis in the character of Christ. But at all events Mani himself, on his own claim, is to be reckoned the last and greatest prophet, who took up the work of Jesus impatibilis and of Paul (for he too finds recognition), and first brought full knowledge. He is the "leader," the "ambassador of the light," the "Paraclete." It is only through his agency and that of his imitators "the elect," that the separation of the light from the darkness can be completed. The system contains very fantastic descriptions of the processes by which the portions of light when once set free finally ascend even to the God of light. He who during his lifetime did not become one of the elect, who did not completely redeem himself, has to go through a severe process of purification on the other side of the grave, till he too is gathered to the blessedness of the light. It is erroneous, however, to ascribe, as has been done, a doctrine of transmigration to the Manichæans. Of course men's bodies as well as the souls of the unsaved, who according to the oldest conception have in them no light whatever, fall under the sway of the powers of darkness. A later view, adapted to the Christian one, represents the portions of light in the unsaved as actually becoming lost. When the elements of light have at last been completely, or as far as possible, delivered from the world, the end of all things comes. All glorious spirits assemble, the God of light himself appears, accompanied by the æons and the perfected just ones. The angels supporting the world withdraw themselves from their burden, and everything falls in ruins. A tremendous conflagration consumes the world; the perfect separation of the two powers takes place once more; high above is the kingdom of light, again brought into a condition of completeness, and deep below is the (now powerless) darkness.

Ethics, social polity, and worship of the Manichæans.

On the basis of such a cosmical philosophy, ethics can only have a dualistic ascetic character. Manichæan ethics is not merely negative, however, since it is necessary to cherish, strengthen, and purify the elements of light, as well as free oneself from the elements of darkness. The aim is not self-destruction, but self-preservation; and yet the ethics of Manichæism appears in point of fact as thoroughly ascetic. The Manichæan had above all to refrain from sensual enjoyment, shutting himself up against it by three seals, the *signaculum oris, manus*, and *sinus*. The *signaculum oris* forbids all eating of unclean food (which included all bodies of animals, wine, &c.,—vegetable diet being allowed because plants contained more light, though the killing of plants, or even plucking their fruit and breaking their twigs, was not permitted), as well as all impure speech. The *signaculum manus* prohibits all traffic with things generally, in so far as they carry in them elements of darkness. Finally by the *signaculum sinus* every gratification of sexual desire, and hence also marriage, is forbidden. Besides all this life was further regulated by an exceedingly rigorous system of fasts. Certain astronomical conjunctions determined the selection of the fast-days, which in their total number amounted to nearly a quarter of the year. Sunday was regularly solemnized as one, and the practice was also generally observed on Monday. Hours of prayer were determined with equal exactness. The Manichæan had to pray four times a day, each prayer being preceded by ablutions. The worshipper turned towards the sun, or the moon, or the north, as the seat of light; but it is erroneous to conclude from this, as has been done, that in Manichæism the sun and moon were themselves objects of worship. Forms of prayer used by the Manichæans have been preserved to us in the *Fihrist*. The prayers are addressed to the God of light, to the whole kingdom of light, to the glorious angels, and to Mani himself, who is apostrophized in them as "the great tree, which is all salvation." According to Kessler, these prayers are closely related to the Mandæan and the ancient Babylonian hymns. An asceticism so strict and painful as that demanded by Manichæism could only be practised by few; hence the religion must have abandoned all attempts at an extensive propaganda, had it not conceded the principle of a twofold morality. A distinction was made in the community between the *Electi* (*Perfecti*), the perfect Manichæans, and the *Catechumeni* (*Auditores*), the secular Manichæans. Only the former submitted themselves to all the demands made by their religion; for the latter the stringency of the precepts was relaxed. They had to avoid idolatry, sorcery, avarice, falsehood, fornication, &c.; above all, they were not allowed to kill any living being (the ten commandments of Mani). They had also to free themselves as much as possible from the world; but in truth they lived very much as their non-Manichæan fellow-citizens. We have here essentially the same condition of things as in the Catholic Church, where a twofold morality was also in force, that of the religious orders and that of secular Christians,—only that the position of the electi in Manichæism was a more distinguished one than that of the monks in Catholicism. For, after all, the Christian monks never quite forgot that salvation is given by God through Christ, whereas the Manichæan electi were actually themselves redeemers. Hence it was the duty of the auditores to pay the greatest respect and most assiduous attention to the electi. These "perfect ones," wasting away under their asceticism, were objects of admiration, and of the most elaborate solicitude.[1] Food was presented to them in abundance, and by their eating it the electi set free the portions of light from the vegetables. They prayed for the auditores, they blessed them and interceded for them, thereby shortening the process of purification the latter had to pass through after death. It was only the electi, too, who possessed full knowledge of religious truths, a point of distinction from Catholicism.

The distinction between electi and auditores, however, does not exhaust the conception of the Manichæan Church; on the contrary, the latter possessed a hierarchy of three ranks, so that there were altogether five gradations in the community. These were regarded as a copy of the ranks of the kingdom of light. At the head stood the *teachers* ("the sons of meekness," Mani himself and his successors); then follow the *administrators* ("the sons of knowledge," the bishops); then the *elders* ("the sons of understanding," the presbyters); the *electi* ("the sons of mystery"); and finally the *auditores* ("the sons of

[1] Analogous to this is the veneration in which the Catholic monks and the Neo-Platonic "philosophers" were held, but the prestige of the Manichæan electi was greater than that of the monks and the philosophers.

insight"). The number of the electi must always have been small. According to Augustine the teachers were twelve, and the bishops seventy-two in number. One of the teachers appears to have occupied the position of superior at the head of the whole Manichæan Church. At least Augustine speaks of such a personage, and the *Fihrist* also has knowledge of a chief of all Manichæans. The constitution, therefore, had a monarchic head.

The worship of the Manichæans must have been very simple, and must have essentially consisted of prayers, hymns, and ceremonies of adoration. This simple service promoted the secret dissemination of their doctrines. The Manichæans too, at least in the West, appear to have adapted themselves to the church's system of festivals. The electi celebrated special feasts; but the principal festival with all classes was the "Bema" (*βῆμα*) the feast of the "teacher's chair," held in commemoration of the death of Mani in the month of March. The faithful prostrated themselves before an adorned but empty chair, which was raised upon a podium of five steps. Long fasts accompanied the feasts. The Christian and Mohammedan historians could learn little of the Manichæan mysteries and "sacraments," and hence the former charged them with obscene rites and abominable usages. It may be held as undoubted that the later Manichæans celebrated mysteries analogous to Christian baptism and the Lord's Supper, which may have rested upon ancient consecration rites and other ceremonies, instituted by Mani himself and having their origin in nature worship.

Historical position of Manichæism.

From the foregoing account it will be evident, as indeed from modern investigation it is certain, that Manichæism did not originate on Christian ground. It would be more proper to speak of Mohammedanism than of Manichæism as a Christian sect; for Mohammed stands in a far closer relation to the Jewish and Christian religions than did Mani. It is Kessler's merit to have shown that the ancient Babylonian religion, the original source of all the gnosis of western Asia, was the basis of the Manichæan system. Hence the erroneousness of the assumption, which formerly prevailed, that Manichæism was a reform movement of Parsism, a modification of Zoroastrianism under the influence of Christianity. Manichæism is a system which rather belongs to the Semitic group of religions. It is the Semitic religion of nature, withdrawn from national limits, modified by Christian and Persian elements, elevated into a gnosis, and transforming human life by the influence of stringent regulations. But the recognition of this fact only supplies us with a very general explanation of the origin of Manichæism. The question still remains, through what channels and to what extent Mani adopted those Persian and Christian elements, and further, in what form the ancient nature religion of Babylonia was utilized by him. As far as the latter point is concerned it is known that, two centuries before Mani, the Semitic nature-religions had already been taken up by various enthusiastic or speculative spirits, who had given them philosophic depth and moulded than into "systems," which were propagated with the aid of mysterious rites. Mani's undertaking, then, was by no means a novel one, but was rather the last in a long series of similar efforts. Again, even in the earlier of these attempts, from that of Simon Magus onward, Christian elements had been adopted to a greater or less extent; and the sects of the Christian gnostic schools of Syria and western Asia may all be traced back to the nature-religions of ancient Semitism, transformed into a philosophy of the world and of life. It is the Babylonian sect of the Moghtasilah that seems to have furnished Mani with the matter of his religious philosophical speculations, and the religion of this sect was purely Semitic (see MANDÆANS; the Mandæans were related to the Moghtasilah). This was the source of the thoroughgoing dualism which forms the basis of Mani's system; for the ancient Persian religion was not essentially dualistic, but was at bottom monistic, since Ahriman is created by Ormuzd. At the same time Mani turned the theologumena of ancient Persia also to account. The fact that the two opposed elements are called "light" and "darkness" can hardly be independent of Parsism, and Manichæism uses other *termini technici* of the Persian religion. Whether Mani's idea of redemption is to be traced to the ancient Babylonian or to the Zoroastrian religion we do not venture to decide. The idea of "the prophet" and "the primal man" is at all events Semitic.

It is very difficult to determine what was the extent of Mani's knowledge of Christianity, how much he himself borrowed from it, and through what channels it reached him. In any case it is certain that Manichæism, in those districts where it was brought much into contact with Christianity, became additionally influenced by the latter at a very early period. The Western Manichæans of the 4th and 5th centuries are much more like Christians than their Eastern brethren. In this respect Manichæism experienced the same kind of development as Neo-Platonism. As regards Mani himself, it is safest to assume that he held both Judaism and Catholic Christianity to be entirely false religions. It is indeed true that he not only described himself as the promised Paraclete—for this designation probably originated with himself—but also conceded a high place in his system to "Jesus;" we can only conclude from this, however, that he distinguished between Christianity and Christianity. The religion which had proceeded from the historical Jesus he repudiated together with its founder, and Catholicism as well as Judaism he looked upon as a religion of the devil. But he distinguished between the Jesus of darkness and the Jesus of light who had lived and acted contemporaneously with the former. This distinction agrees with that made by the gnostic Basilides no less strikingly than the Manichæan criticism of the Old Testament does with that propounded by the Marcionites (see the *Acta Archelai*, in which Mani is made to utter the antitheses of Marcion). Finally the Manichæan doctrines exhibit points of similarity to those of the Christian Elkesaites; but, as it is possible, and even probable, that such resemblances are to be ascribed to a common ancient Semitic source, they do not here call for further consideration. The historical relation of Mani to Christianity is then as follows. From Catholicism, which he very probably had no detailed knowledge of, he borrowed nothing, rejecting it as devilish error. On the other hand, he looked upon what he considered to be Christianity proper, that is, Christianity as it had been developed among the sects of Basilidians, Marcionites, and perhaps Bardesanites, as a comparatively valuable and sound religion. He took from it, however, as from the Persian religion, hardly anything but names, and, perhaps we may add, a criticism of the Old Testament and of Judaism so far as he required it. Indications of the influence of Marcionitism are found in the high estimation in which Mani held the apostle Paul, and in the fact that he explicitly rejects the Book of Acts. Mani appears to have given recognition to a portion of the historical matter of the Gospels, and to have interpreted it in accordance with his own doctrine. In conclusion, it remains to be asked whether Buddhistic elements can also be detected in Manichæism. Most modern scholars since F. C. Baur have answered this question in the affirmative. According to Kessler, Mani made use of the teaching of Buddha, at least as far as ethics was concerned. It cannot be doubted that Mani, who undertook long journeys as far as India.

knew of Buddhism. The name Buddha (Buddas) which occurs in the legendary account of Mani, and perhaps in the latter's own writings, indicates further that he had occupied his attention with Buddhism when engaged in the work of founding his new religion. But his borrowings from this source must have been quite insignificant. A detailed comparison shows the difference between Buddhism and Manichæism in all their principal doctrines to be very great, while it becomes evident that the points of resemblance are almost everywhere accidental. This is also true of the ethics and the asceticism of the two systems. There is not a single point in Manichæism which demands for its explanation an appeal to Buddhism. Such being the case, the relationship between the two religions remains a mere possibility, a possibility which the inquiry of Geyler (*Das System des Manichæismus und sein Verhältniss zum Buddhismus*, Jena, 1875) has not been able to elevate into a probability.

How are we to explain the rapid spread of Manichæism, and the fact that it really became one of the great religions? One answer is that Manichæism was the most complete gnosis, the richest, most consequent, and most artistic system formed on the basis of the ancient Babylonian religion (so Kessler). This explanation is insufficient, for no religion operates mainly through the perfection of its system of doctrine; and it is not strictly correct, for the older gnostic systems were not less richly equipped than the Manichæan. What gave strength to Manichæism was rather that it united an ancient mythology and a thoroughgoing materialistic dualism with an exceedingly simple spiritual worship and a strict morality. On comparing it with the Semitic religions of nature, we perceive that it retained their mythologies, after transforming them into "doctrines," but abolished all their sensuous cultus, substituting instead a spiritual worship as well as a strict morality. Manichæism was thus able to satisfy the new wants of an old world. It offered revelation, redemption, moral virtue, and immortality, spiritual benefits on the basis of the religion of nature. A further source of strength lay in the simple yet firm social organization which was given by Mani himself to his new institution. The wise man and the ignorant, the enthusiast and the man of the world, could all find acceptance here, and there was laid on no one more than he was able and willing to bear. Each one, however, was attached and led onward by the prospect of a higher rank to be attained, while the intellectually gifted had an additional inducement in the assurance that they did not require to submit themselves to any authority, but would be led to God by pure reason. Thus adapted from the first to individual requirements, this religion also showed itself able to appropriate from time to time foreign elements. Originally furnished from fragments of various religions, it could increase or diminish this possession without rupturing its own elastic framework. And, after all, great adaptability is just as necessary for a universal religion as a divine founder in whom the highest revelation of God Himself may be seen and reverenced. Manichæism indeed, though it applies the title "redeemer" to Mani, has really no knowledge of a redeemer, but only of a physical and gnostic process of redemption; on the other hand, it possesses in Mani the supreme prophet of God. If we consider in conclusion that Manichæism gave a simple, apparently profound and yet convenient solution of the problem of good and evil, a problem that had become peculiarly oppressive to the human race in the 2d and 3d centuries, we shall have named the most important factors which account for the rapid spread of the system.

Manichæism first gained a firm footing in the East, *i.e.*, in Persia, Mesopotamia, and Transoxania. The persecutions it had to endure did not hinder its extension. The seat of the Manichæan pope was for centuries in Babylon, at a later period in Samarkand. Even after the conquests of Islam the Manichæan Church continued to maintain itself, indeed it seems to have become still more widely diffused by the victorious campaigns of the Mohammedans, and it frequently gained secret adherents among the latter themselves. Its doctrine and discipline underwent little change in the East; in particular, it drew no nearer to the Christian religion. More than once, however, Manichæism experienced attempts at reformation; for of course the auditores very easily became worldly in character, and movements of reformation led temporarily to divisions and the formation of sects. Towards the close of the 10th century, at the time the *Fihrist* was written, the Manichæans in Mesopotamia and Persia had already been in large measure ousted from the towns, and had withdrawn to the villages. But in Turkestan, and as far as the Chinese frontier, there existed numerous Manichæan communities, and even whole tribes that had adopted the name of Mani. Probably it was the great migrations of the Mongolian race that first put an end to Manichæism in Central Asia. But even in the 15th century there were Manichæans living beside the Thomas-Christians on the coast of Malabar in India (see Germann, *Die Thomas-Christen*, 1875). Manichæism first penetrated the Greek-Roman empire about the year 280, in the time of the emperor Probus (see the *Chronicon* of Eusebius). If we may take the edict of Diocletian against the Manichæans as genuine, the system must have gained a firm footing in the West by the beginning of the 4th century, but we know that as late as about the year 325 Eusebius had not any accurate knowledge of the sect. It was only subsequent to about 330 that Manichæism spread rapidly in the Roman empire. Its adherents were recruited on the one hand from the old gnostic sects (especially from the Marcionites,—Manichæism exerted besides this a strong influence on the development of the Marcionite churches of the 4th century), on the other hand from the large number of the "cultured," who were striving after a "rational" and yet in some manner Christian religion. Its polemics and its criticism of the Catholic Church now became the strong side of Manichæism, especially in the West. It admitted the stumbling-blocks which the Old Testament offers to every intelligent reader, and gave itself out as a Christianity without the Old Testament. Instead of the subtle Catholic theories concerning divine predestination and human freedom, and instead of a difficult theodicæa, it offered an exceedingly simple conception of sin and goodness. The doctrine of the incarnation of God, which was especially objectionable to those who were going over to the new universal religion from the old cults, was not proclaimed by Manichæism. In its rejection of this doctrine Manichæism agreed with Neo-Platonism; but, while the latter, notwithstanding all its attempts to conform itself to Christianity, could find no formula by which to inaugurate within its own limits the special veneration of Christ, the Western Manichæans succeeded in giving their teaching a Christian tinge. The only part of the Manichæan mythology that became popular was the crude, physical dualism. The barbaric elements were judiciously screened from view as a "mystery;" they were, indeed, here and there explicitly disavowed even by the initiated. The further Manichæism advanced into the West, the more Christian and philosophic did it become. In Syria it maintained itself in comparative purity. In North Africa it found its most numerous adherents, gaining secret support even among the clergy. The explanation of this perhaps lies in the fact that one part of the population of North Africa was of Semitic origin. Augustine was an

auditor for nine years, while Faustus was at that time the most esteemed Manichæan teacher in the West. Augustine in his later writings against the Manichæans deals chiefly with the following problems:—(1) the relation between knowledge and faith, and between reason and authority; (2) the nature of good and evil, and the origin of the latter; (3) the existence of free will, and its relation to the divine omnipotence; (4) the relation of the evil in the world to the divine government.

The Christian Byzantine and Roman emperors, from Valens onwards, enacted strict laws against the Manichæans. But at first these bore little fruit. The auditores were difficult to trace out, and besides they really gave little occasion for persecution. In Rome itself between 370 and 440 Manichæism gained a large amount of support, especially among the scholars and public teachers. It also made its way into the life of the people by means of a popular literature in which the apostles were made to play a prominent part (*Apocryphal Acts of the Apostles*). Manichæism in the West had also some experience of attempts at reformation from the ascetic side, but of these we know little. In Rome Leo the Great was the first who took energetic measures, along with the state authorities, against the system. Valentinian III. decreed banishment against its adherents, Justinian the punishment of death. In North Africa Manichæism appears to have been extinguished by the persecution of the Vandals. But it still continued to exist elsewhere, both in the Byzantine empire and in the West, and in the earlier part of the Middle Ages it gave an impulse to the formation of new sects, which remained related to it. And, if it has not been quite proved that so early as the 4th century the Priscillianists of Spain were influenced by Manichæism, it is at least undoubted that the Paulicians and Bogomiles as well as the Catharists and the Albigenses are to be traced back to Manichæism (and Marcionitism). Thus the system, not indeed of Mani the Persian, but of Manichæism as modified by Christian influences, accompanied the Catholic Church until the 13th century.

*Sources.*—(*a*) Oriental. Among the sources for a history of Manichæism, the most important are the Oriental. Of these the Mohammedan, though of comparatively late date, are distinguished by the excellent manner in which they have been transmitted to us, as well as by their impartiality. They must be named first, because ancient Manichæan writings have been used in their construction, while, with the exception of some small and rather unimportant pieces, we possess no other original Manichæan works dating from the 3d century. At the head of all stands En-Nedím, *Fihrist* (*circa* 980), edited by Flügel (1871–72); comp. the latter's work *Mani, seine Lehre u. seine Schriften*, 1862. See also Shahrastáni, *Kitáb al-milal wan-nuhal* (12th cent.), edited by Cureton (1846) and translated into German by Haarbrücker, 1851, and individual notes and excerpts by Tabarí (10th cent.), Al-Bírúní (11th cent.), and other Arabian and Persian historians.

Of the Christian Orientals those that afford most information are Ephraem Syrus (ob. 373), in various writings; the Armenian Esnik (see *Zeitsch. f. hist. Theol.*, 1840, ii.; Langlois, *Collection*, ii. 375 *sq.*), who wrote in the 5th century against Marcion and Mani; and the Alexandrian patriarch Eutychius (*ob.* 916), *Annales*, ed. Pococke, 1628. There are besides scattered pieces of information in Aphraates (4th cent.), Barhebræus (13th cent.), and others.

(*b*) Greek and Latin. The earliest mention of the Manichæans in the Græco-Roman empire is to be found in an edict of Diocletian (see Hänel, *Cod. Gregor.*, tit. xv.), which is held by some to be spurious, while others assign it to one or other of the years 287, 290, 296, 308 (so Mason, *The Persec. of Diocl.*, p. 275 *sq.*). Eusebius gives a short account of the sect (*H. E.*, vii. 31). It was the *Acta Archelai*, however, that became the principal source on the subject of Manichæism for Greek and Roman writers. These *Acta* are not indeed what they give themselves out for, viz., an account of a disputation held between Mani and the bishop Archelaus of Cascar in Mesopotamia; but they nevertheless contain much that is trustworthy, especially regarding the doctrine of Mani, and they also include Manichæan documents. They consist of various distinct pieces, and originated in the beginning of the 4th century, probably at Edessa. They were translated as early as the first half of the same century from the Syriac (as is maintained by Jerome, *De Vir. Illust.*, 72; though this is doubted by modern scholars) into Greek, and soon afterwards into Latin. It is only this secondary Latin version that we possess (edited by Zacagni, 1698; Routh, *Reliq. Sac.*, vol. v., 1848; translated in Clark's *Ante-Nicene Library*, vol. xx.); small fragments of the Greek version have been preserved. Regarding the *Acta Archelai*, see Zittwitz in *Zeitschr. f. d. histor. Theol.*, 1873, and Oblasinski, *Acta disp. Arch. et Manetis*, 1874. In the form in which we now possess them, they are a compilation after the pattern of the *Clementine Homilies*, and have been subjected to manifold redactions. These *Acta* were used by Cyril of Jerusalem (*Catech.*, 6), Epiphanius (*Hær.*, 66), and a great number of other writers. All the Greek and Latin heresiologists have included the Manichæans in their catalogues; but they seldom adduce any independent information regarding them (see Theodoret, *Hær. fab.*, i. 26). Important matter is to be found in the resolutions of the councils from the 4th century onwards (see Mansi, *Acta Concil.*, and Hefele, *Conciliengeschichte*, vol. i.–iii.), and also in the controversial writings of Titus of Bostra (6th cent.), Πρὸς Μανιχαίους (ed. Lagarde, 1859), and of Alexander of Lycopolis, Λόγος πρὸς τὰς Μανιχαίου δόξας (ed. Combefis; transl. in *Ante-Nic. Lib.*, vol. xiv. Of the Byzantines, the most worthy of mention are John of Damascus (*De Hæres.* and *Dialog.*) and Photius (*cod.* 179 *Biblioth.*). The struggle with the Paulicians and the Bogomiles, who were often simply identified with the Manichæans, again directed attention to the latter. In the West the works of Augustine are the great repertory for information on the subject of Manichæism (*Contra epistolam Manichæi, quam vocant fundamenti*; *Contra Faustum Manichæum*; *Contra Fortunatum*; *Contra Adimantum*; *Contra Secundinum*; *De actis cum Felice Manichæo*; *De Genesi c. Manichæos*; *De natura boni*; *De duabus animabus*; *De utilitate credendi*; *De moribus eccl. cathol. et de moribus Manichæorum*; *De hæres.*). The more complete the picture, however, which may here be obtained of Manichæism, the more cautious must we be in making generalizations from it, for it is beyond doubt that Western Manichæism adopted Christian elements which are wanting in the original and in the Oriental Manichæism.

*Literature.*—The most important works on Manichæism are Beausobre, *Hist. critique de Manichée et du Manichéisme*, 2 vols., 1734 *sq.* (the Christian elements in Manichæism are here strongly, indeed too strongly, emphasized); Baur, *Das manich. Religionssystem*, 1831 (in this work Manichæan speculation is exhibited from a speculative standpoint); Flügel, *Mani*, 1862 (a very careful investigation on the basis of the *Fihrist*); Kessler, *Untersuchung zur Genesis des manich. Religionssystems*, 1876; and the article "Mani, Manichäer," by the same writer in Herzog-Plitt's *R. E.*, ix. 223–59. This article is very thorough, and leads to most favourable expectations regarding the author's forthcoming work. The accounts of Mosheim, Lardner, Walch, and Schröckh, as well as the monograph by Trechsel, *Ueber Kanon, Kritik, und Exegese der Manichäer*, 1832, may also be mentioned as still useful. The various researches which have been made regarding Parsism, the ancient Semitic religions, Gnosticism, &c., are of the greatest importance for the investigation of Manichæism. (A. HA.)

MANILA (less correctly MANILLA), the capital of Luzon and the Philippine Islands, and the centre of Spanish commerce in the East, was founded by Legaspi in 1571, and is situated on the eastern shore of a circular bay 120 nautical miles in circumference, 14° 36′ N. lat. and 120° 52′ E. long. The country around the bay is more or less flat in character, and in the dry season almost bare of vegetation, so that, excepting the Mafonso and Matéo mountains behind Manila, and the chains of mountains running north and south of the entrance to the bay, there is really nothing attractive about the harbour. It is unsafe in the north-east and south-west monsoons, and vessels over 300 tons have to run for shelter to the naval port of Cavité, the smaller craft finding a safe anchorage behind a breakwater facing the mouth of the Pasig. A new breakwater, however, was commenced in 1880 for large vessels. This river Pasig, which is about 14 miles long, is fed by an inland lake called the Laguna de Bayo, and on its way into the harbour it divides Manila into two parts. On its northern bank are large commercial warehouses, a bazaar occupied chiefly by Chinese, known as the Escolta, and trending eastwards an extensive suburb of native dwellings extending some miles up the Pasig. Beyond the Escolta lie Binondo, the business part of Manila, and San Miguel, the fashionable quarter where Spaniards and foreigners have their residence, and where since the earthquake of 1880 two palaces

have been erected for the governor or captain-general and for the admiral of the fleet. There are numerous churches and barracks in this part of the town, and several public buildings, of which the following may be mentioned,—the hospital of St Lazarus, the *garnero* or large military storehouse, and the famous cigar factory, covering a space of about 6 acres, and employing daily 10,000 women. Beyond and blending as it were with Binondo are villages in which the governor has his country house, and where Europeans have built pretty villa residences. A stone bridge and a new suspension bridge connect Binondo or modern Manila with the suburb opposite and the old fort of St Iago, situated on the south bank and about a mile from the mouth of the Pasig. Within the fort wall lies the old city, or, as it is commonly called, the Plaza de Manila. It is approached by several gates—the principal being the Entrada, near which stands the custom-house. It has several squares, and the streets running at right angles with each other are fairly broad and clean, but, as no trade is carried on in this part of the town, they are dull by day, and, as only oil lamps are used, gloomy by night. The public edifices, such as the governor's palace, the town-hall, and the cathedral, are in a large square, in the centre of which is a statue of Charles IV. surrounded by a garden of flowers. To these may be added the civil and military hospitals, the mint and museum, the university and the academy of arts, the arsenal, the prison, and numerous barracks, convents, and monasteries. Beyond the walls is the *calzada* or esplanade, with a small *paseo* or promenade facing the bay, where three or four military bands play twice a week to a large concourse of people. This forms the chief out-door attraction for the élite of Manila. There are two theatres—occasionally visited by European companies; but there is a want of the cafés and bull fights so associated with Spanish life. Evening receptions are given by the Spaniards, where cards and music serve to while away the time, and the well-to-do *Tagalo*, besides imitating his masters in all their amusements, has another to which he is passionately addicted, viz., cock-fighting. This is under Government control, and in town can only be held in licensed cockpits, which in 1878 yielded above £33,000 to the revenue. The native officials may sometimes be a little officious and overbearing; but the natives generally, especially those out of Manila, are as hospitable to the stranger as the Spaniard.

The population in the walled town, inclusive of the garrison, is given in the consular reports for 1880 as 12,000, and that of Binondo and the suburbs as 250,000 to 300,000. In 1842 the total was rather more than 150,000.

The climate is healthy, and though hot is not unbearably so, the mean temperature being about 82°·6 Fahr. The hot season prevails from March to the end of June; the rest of the year may be said to be showery and stormy. The chief climatic drawbacks to a residence in Manila are hurricanes, earthquakes, and fearful thunderstorms. Great damage was done to property by a tornado of exceptional severity in October 1882.

The cemetery of Manila is well suited for a hot climate and the backward condition of its sanitary arrangements. It is a large circular area, surrounded by an outer and an inner wall, with horizontal recesses between them placed one above another in tiers. On the arrival of a body for sepulture it is taken out of its coffin and put into one of these recesses; quicklime is then spread upon it and the mouth of the recess bricked up. If the recess is the property of the relatives of the dead, the body remains undisturbed for ever. If otherwise, it remains until the recess is absolutely required for another inmate; when the bones, the only remains left of the deceased, are collected and carefully deposited in a large hollow or fosse kept for that purpose.

For two centuries after the Spanish settlement the trade of Manila with the Western world was carried on *via* Acapulco and Mexico; and it was not till 1764 that even the Spanish vessels began to come round by the Cape. The port, however, was opened with some restrictions to foreign vessels in 1789; permission for the establishment of an English commercial house was granted in 1809; the same liberty was before long extended to other nationalities; and in 1834 the privileges of the Royal Company of the Philippines expired and left the commercial movement to its natural tendencies. Since that time the trade of Manila has greatly increased. While in 1840 the port was entered by 187 vessels with a burden of about 57,000 tons, the corresponding figures for 1881 are, including 182 steamers, 317 vessels (British, 118; Spanish, 95; German, 38), with a burden of 244,000 tons. Manila hemp (*abaca*), sugar, cigars, and coffee are the chief articles of export; and sapan wood, mother of pearl, and gum are regular though secondary items. The quantity of hemp shipped at Manila has increased from 528,206 piculs (1 picul = 139 lb) in 1877 to 662,886 in 1881, and in the same period the quantity of sugar has risen from 1,215,066 piculs to 2,001,310. Britain and the United States are the great markets for both. The average number of cigars exported is 92,620,000, the greater proportion going to Singapore and China. The total value of the exports was £5,460,000 in 1881, against £2,679,000 in 1864; and a corresponding increase has taken place in the imports.

Telegraphic communication between Manila and Hong-Kong was established in 1880.

MANILA HEMP, the most valuable of all fibres for cordage, is the produce of the leaf-stalks of *Musa textilis*, a native of the Philippine Islands. The plant, called *abaca* by the islanders, throws up a spurious stem from its rhizome, consisting of a cluster of sheathing leaf-stalks which rise to a height of from 20 to 30 feet, and spread out into a crown of huge undivided leaves characteristic of the various species of *Musa* (plantain, banana, &c.). In its native regions the plant is rudely cultivated solely as a source of fibre; it requires little attention, and when about three years old develops flowers on a central stem, at which stage it is in the most favourable condition for yielding fibre. The stock is then cut down, and the sheathing stalks torn asunder and reduced to small strips. These strips in their fresh succulent condition are drawn between a sharp knife-edged instrument and a hard wooden block to which it is fixed, and by repeated scraping in this way the soft cellular matter which surrounds the fibre is removed, and the fibre so cleaned has only to be hung up to dry in the open air, when, without further treatment, it is ready for use. Each stock yields, on an average, a little under 1 lb of fibre; and two natives cutting down plants and separating fibre will prepare not more than 25 lb per day. The fibre yielded by the outer layer of leaf-stalks is hard, fully developed, and strong, but the produce of the inner stalks is increasingly thin, fine, and weak. The finer fibre is used by the natives, without spinning or twisting (the ends of the single fibres being knotted together), for making exceedingly fine, light, and transparent yet comparatively strong textures, which they use as articles of dress and ornament. The hemp exported for cordage purposes is a somewhat woody fibre, of a bright brownish-white colour, and possessing great durability and strain-resisting power. It contains a very considerable amount of adherent pectinous matter, and an unusually large proportion, as much as 12 per cent., of water in a dry condition. In a damp atmosphere the fibre absorbs moisture so freely that it has been found to contain not less than 40 per cent. of water, a circumstance which dealers in the raw fibre should bear in mind. The plant has been introduced into many tropical lands; but the cheapness of labour in its native regions, and its abundance there, prevent its being a profitable substance for general cultivation. The entire supply comes from Manila and Cebu in the Philippine Islands, where its cultivation and preparation must give employment to a very large population. The exports, which are increasing with great rapidity, amounted in 1881 to about 400,000 bales of 2½ cwts. each, almost the whole of which goes to the United Kingdom, the United States, and the Australian colonies. The quantity imported into

the United Kingdom in 1881 was 346,908 cwts., valued at £678,514. The fibre is now so valuable that manila hemp cordage is freely adulterated by manufacturers, chiefly by admixture of phormium (New Zealand flax) and Russian hemp.

MANILIUS, a Roman poet, was the author of a poem in five books called *Astronomica*. Nothing is recorded of the author; he is neither quoted nor mentioned by any ancient writer. His very name is uncertain, but was probably Marcus Manilius. From the work itself it may be gathered with much probability that the writer lived under Augustus or Tiberius, and that he was a citizen of and resident in Rome. He bears the name of a distinguished plebeian family. His work is one of great learning; he had studied his subject in the best writers, and generally represents the most advanced views of the ancients on astronomy. It is, however, destitute of poetical or literary merit. It is difficult to explain how a work of such learning on a subject which was studied with such interest by the ancients should have remained so neglected. Firmicus, who wrote in the time of Constantine, has so many points of resemblance with the work of Manilius that he must either have used him or have followed some work that Manilius also followed. As Firmicus says that hardly any Roman except Cæsar, Cicero, and Fronto had treated the subject, it is probable that he did not know the work of Manilius. The latest event referred to in the poem is the great defeat of 9 A.D.

MANIN, Daniele (1804–1857), president of the Venetian republic in 1848–49, and one of the principal founders of Italian independence, was born in Venice on the 13th May 1804. He studied at Padua, graduating as doctor of laws when only seventeen years of age, and soon after translated Pothier's large treatise *Sur le Droit Romain*. To his father, an eminent barrister, he was indebted not only for much of his skill in jurisprudence but for his strong republican bias, having as a boy constantly heard him denounce indignantly the injustice of Bonaparte in handing Venice over to Austria by the scandalous treaty of Campio Formio. In 1830 Manin commenced practice as an advocate, but only to become conscious of the harsh restrictions laid by Austria upon the administration of law. That and the following year showed some stirrings of political life in Italy; and Manin, already the leading spirit in Venetia of the new national party, strove to train his countrymen to united purpose and action. The question of a railway to Milan, for instance, or whether the Indian mail should go by Venice, was utilized to quicken the patriotic instinct by thwarting the Government, and that without neglecting the great principle "legality and publicity"—which till 1848 was his unswerving rule of conduct.

In 1847 he spoke ably on political economy at the scientific congress held in Venice, and soon after presented two petitions to the "congregation,"—a shadowy deliberative assembly which was tolerated by Austria. His principal demands were—separate government of Venice and Lombardy, revision of the code, an annual budget, freedom of the press, and religious equality. On the 18th January 1848, soon after Radetsky's cruel treatment of Milan, he was arrested, but only to intensify the patriotic enthusiasm of the people. The population of Venice marched past his prison silently and mournfully, every head uncovered. The carnival (that year spent in gloom) was scarcely over, however, when the glad news from Sicily, Naples, and Paris so worked upon their minds that the Austrian authorities were forced to feel that the revolutionary wave had reached Venice. On the 17th March Manin was carried in triumph to the Place St Mark, and virtually declared dictator. Now that the moment for action was come he immediately formed a civic guard, and by his energy and earnestness inspired all classes of the citizens to act as one man. On the 22d the dictator became president of the new republic of St Mark, to cope alone with all the difficulties of administration, organization, and finance. In March 1849, on the defeat of King Charles Albert, Venice had to prepare herself resolutely for defence; and on the 2d April there was passed in the palace of the Doges a decree in two clauses:— "(1) Venice will resist the Austrians at whatever cost; (2) the president Manin is invested with unlimited powers." On the 26th May one outlying fort was taken, but on the 3d July, when Rome and Mazzini had succumbed to the French, Venice and Manin were still strenuous in their heroic defence. Only when cholera had also attacked them, when food and ammunition were spent and people were dying of hunger, when every house not burned down was riddled by the shot and shell of the bombardment, and no gleam of hope from without was visible, was the capitulation signed, 24th August, on terms of amnesty to all except the president and thirty-nine other citizens.

Leaving Venice on the 27th, with his wife and two children, Manin spent the rest of his life in Paris, where he maintained a modest independence by teaching his native language. His energies were still devoted to the unification of Italy, so that, whether as a republic or as a kingdom, she might be freed from Austrian domination. He died of heart disease on the 22d September 1857, and was buried in the family tomb of Ary Scheffer. In 1868 the remains were removed to Venice, and honoured with a public funeral.

See Henri Martin, *D. Manin*, 1859, and *L'Unité Italienne*, 1861 (Martin also wrote the article in the *Biogr. Universelle*); C. L. Chassin, *Manin et l'Italie*; Errera's *Vita di D. Manin*, Venice, 1872; P. de La Faye's *Documents, &c., de D. Manin*, 1860. Other writers are Ernest Legouvé, A. de La Forge, and Edmund Flagg (New York).

MANIOC or Mandioc. See Cassava and Arrow-root.

MANIPUR, a native state in north-eastern India, lying between 24° 35′ and 24° 48′ 30″ N. lat., and between 93° and 94° 40′ E. long., is bounded on the N. by the Nága country and the hills overlooking the Assam valley, on the W. by Cáchár district, and on the E. by Independent Burmah. On the south the boundary is undefined, and abuts on the country inhabited by various independent wild hill tribes of Lushais, Kukis, &c. The state consists of an extensive valley, estimated at about 650 square miles in extent, and a large surrounding unsurveyed tract of difficult mountainous country stretching between Assam, Cáchár, Burmah, and Chittágong. The total area is estimated at about 7600 square miles. The population of the Manipur valley and the surrounding hills is supposed to be about 74,000 hill-men and 65,000 Manipuris. The hill ranges generally run north and south, with occasional connecting spurs and ridges of lower elevation between. Their greatest altitude is in the north, where they reach to upwards of 8000 feet above sea-level. The principal geographical feature in the valley is the Logtak Lake, an irregular sheet of water of considerable size, but said to be yearly growing smaller. The valley is watered by numerous rivers, the Bárak being the most important. The hills are densely clothed with tree jungle and large forest timber. There are large herds of wild elephants, as well as tigers, leopards, bears, buffaloes, &c. The country seems to be singularly free from poisonous snakes: the cobra does not appear to exist in the valley, but the boa constrictor is found in the dense forests to the south.

The first relations of the British with Manipur date from 1762, when the rájá solicited British aid to repel a Burmese invasion and a treaty was entered into. The force was recalled, and

but little communication between the two countries took place until 1824, on the outbreak of the first British Burmese war. British assistance was again invoked by the rájá, and the Burmese were finally expelled both from the Assam and Manipur valleys. A political agent acts as a means of communication between the state and the British Government. Manipur valley appears to have been originally occupied by several tribes which came from different directions. Although their general facial characteristics are Mongolian, there is a great diversity of feature among the Manipuris, some of them showing a regularity approaching the Aryan type. In the valley the people are chiefly Hindus, that religion being apparently of recent introduction. They have a caste system of their own, different from that of India, and chiefly founded on what is known as the system of *lallâp* or forced labour. Every male between the ages of seventeen and sixty is obliged to place his services at the disposal of the state for a certain number of days each year, and to different classes of the people different employments are assigned. About four hundred Mohammedan families, descendants of settlers from Bengal, reside to the east of the capital. The aboriginal hill-men belong to one of the two great divisions of Nágas and Kukis, and are subdivided into innumerable clans and sections with slight differences in language, customs, or dress. The state is noted for the excellence of its breed of ponies. The now popular English game of polo was introduced from Manipur, where it forms a great national pastime. The trade is but small, owing chiefly to the want of means of transport, none of the roads being available for wheeled carts.

MANIS. See PANGOLIN.

MANISA, or MANISSA, a town of Asia Minor or Anatolia, situated on the north side of Mount Sipylus, 28 miles north-east of Smyrna. This town was anciently called *Magnesia ad Sipylum* (see MAGNESIA). It is situated on the banks of the Hermus, and is noted as being one of the neatest and cleanest cities in Asia Minor. It contains above twenty mosques, two of which are adorned on the exterior with double minarets, and in the inside with paintings and other articles. The Armenians, Greeks, and Jews have also their respective places of worship. There is also a fine khan, and a citadel, which stands on a lofty rock, and commands an extensive view. The surrounding country is rich and productive, especially of saffron, which is exported. The town is the seat of some considerable trade, and many of the inhabitants are employed in the manufacture of cotton and silk goods and goats' hair shawls. Population about 40,000. The town is now connected with Smyrna by a railway, which is continued on to Ala-Shehr (Philadelphia). A few miles from Manisa is a colossal statue cut in the rock, which is generally supposed to be the figure of Niobe, alluded to by ancient authors.

MANISTEE, a city of the United States, the county seat of Manistee county, Michigan, is situated 135 miles north-west of Lansing, on the east side of Lake Michigan, at the mouth of the Manistee river, which is navigable for vessels drawing 10 to 12 feet of water for the distance of 1½ miles to Manistee Lake. It is a great seat of the lumber trade, shipping annually 200,000,000 feet of timber, and having a score of saw-mills and about as many shingle mills, the latter of which produce in the year 400,000,000 shingles,—the largest quantity made at any one place in the world. Planing-mills and foundries are also maintained; and, in consequence of the discovery in 1881 of a bed of solid salt 30 feet thick, extensive salt factories are being built. The surrounding district is especially adapted for fruit-growing; and sportsmen are attracted to the Manistee river and its tributaries by the abundance of the rarely found grayling. The population, 3373 in 1870, was 7080 in 1880.

MANITOBA, one of the western provinces of the Dominion of Canada, is situated midway between the Atlantic and the Pacific coasts of the Dominion, about 1090 miles due west of Quebec (see vol. iv. plate XXXV.). It is bounded on the S. by the parallel 49° N. lat., which divides it from the United States; on the W. by 101° 20′ W. long; on the N. by 52° 50′ N. lat.; and on the E. by the western boundary of Ontario. Manitoba formerly belonged to the HUDSON'S BAY COMPANY (*q.v.*), and was, after the transfer of their territory to Canada, admitted in 1870 as the fifth province of the Dominion. At that time the infant province had an area of 13,500 square miles, and some 12,000 people, chiefly Indian half-breeds. In 1881 the limits were increased to the extent indicated above, and now contain, taking the Lake of the Woods as the eastern boundary, upwards of 80,000 square miles, an area only 8782 square miles less than that of England and Scotland together, extending 264 miles from north to south and upwards of 300 from east to west. The old district of Assiniboia, the result of the efforts in colonization by the earl of Selkirk in 1811 and succeeding years, was the nucleus of the province. Manitoba was so called by the Dominion parliament after the lake of that name; the designation is usually considered to be a compound of the Ojibway words, Manito, great spirit, and Waba, straits between lakes, or a word meaning echo.

The drainage of Manitoba is entirely north-eastward to Hudson's Bay. The three lakes—whose greatest lengths are 250, 150, and 130 miles respectively—are Winnipeg, Winnipegoosis, and Manitoba. They are all of a very varying and irregular shape, but average respectively 30, 18, and 10 miles in width. They are fresh, shallow, and tideless. Winnipegoosis and Manitoba at high water, in spring time, discharge their overflow through small streams into Winnipeg. The chief rivers emptying into Lake Winnipeg are the Winnipeg, the Red, and the Saskatchewan. The Assiniboine river, with its source in the province, and navigable from 250 to 350 miles for steamers of light draught, enters the Red river 45 miles from Lake Winnipeg, and at the confluence of the rivers ("The Forks") is situated the city of Winnipeg. The Winnipeg, which flows from the territory lying south-east of Lake Winnipeg, is a noble river some 200 miles long, that after leaving Lake of the Woods, dashes with its clear water over many cascades, and traverses very beautiful scenery. At its falls from Lake of the Woods is one of the greatest and most easily utilized water-powers in the world. Like most rivers in the New World, the Red river is at intervals of years subject to freshets. In the seventy years' experience of the Selkirk colonists there have been four "floods." The highest level of the site of the city of Winnipeg is said to have been under 5 feet of water for several weeks in May and June in 1826, under 2½ feet in 1852, not covered in 1861, and only under water on the lowest levels in 1882. The extent of overflow has thus on each occasion been less. The loose soil on the banks of the river is every year carried away in great masses, and the channel has so widened as to render the recurrence of an overflow unlikely. The Saskatchewan, though not in the province, empties into Lake Winnepeg less than half a degree from the northern boundary. It is a mighty river, rising in the Rocky Mountains, and crossing eighteen degrees of longitude. Near its mouth are the Grand Rapids. Above these, steamers ply to Fort Edmonton, a point upwards of 800 miles north-west of the city of Winnipeg. Steamers run from Grand Rapids, through Lake Winnipeg, up Red river to the city of Winnipeg.

Geologically Manitoba may be said to be the resumption of the Secondary rocks left behind in the fertile portions of Ontario. The whole north-east of North America, running from Labrador, crossing the Ottawa, and skirting the Georgian Bay and Lake Superior, is a region of Laurentian or Primary rocks—containing copper, silver, and probably gold-bearing rocks. From Lake Superior north-westward to within 40 miles of Red river and up to the eastern shore of Lake Winnipeg the same region continues for about 500 miles, including near its western limits the Lake of the Woods. This barren region left behind, the

fertile plains of Manitoba begin—a district resting on Silurian limestones. For 100 or 150 miles these rocks continue. This is the first prairie steppe. At very few points does an outcrop of limestone occur. A range of hills running from south-east to north-west bounds this region on the west. These are Pembina Mountains, Riding Mountains, and Duck Mountain, varying from 200 to 700 feet in height. Before the Riding Mountains are reached, on the shores and islands of Lakes Manitoba and Winnipegoosis are found a few buff-coloured Devonian limestones. From this line of hills westward spreads out the second prairie steppe, extending some 400 or 500 miles. Beyond this for an equal distance, at a still higher elevation, is the third prairie steppe, till the Rocky Mountains are reached. From the Pembina and Riding Mountains to the Rocky Mountains, say 1000 miles, Cretaceous beds underlie the plains and crop out at long intervals. The most striking feature of this formation, of which only the eastern 100 or 150 miles are within Manitoba, is the presence of coal. It is, like most of the Tertiary varieties, a lignite; a specimen analysed gives water 7·82 per cent., volatile combustible matter 31·35 per cent., fixed carbon 54·97 per cent., and ash 5·86 per cent. The supply of this coal is, according to Professor Selwyn, practically inexhaustible. Mr G. M. Dawson, Government explorer, has figured exposures of lignite 1 foot, 7 feet, and even 18 feet in thickness in the Souris valley, 250 miles south-west of Winnipeg. As a fuel for domestic purposes, this coal in general answers very well. The drift deposit on the first and second prairie levels varies from 20 to 100 feet, and consists of clay and boulders. A clay lying near the surface is used for making the white brick of which Winnipeg is built. The most recent geologic deposit is a rich vegetable mould, sometimes 4 feet in thickness. It is this that gives the reputation for fertility which the soil of the province enjoys.

The surface of Manitoba is somewhat level and monotonous. It is chiefly a prairie region, with treeless plains of from 5 to 40 miles extent, covered in summer with an exuberant vegetable growth, which dies every year. The river banks are, however, fringed with trees, and in the more undulating lands the timber belts vary from a few hundreds of yards to 5 or 10 miles in width, forming at times forests of no inconsiderable size. The chief trees of the country are the aspen (*Populus tremuloides*), the ash-leaved maple (*Negundo aceroides*), oak (*Quercus alba*), elm (*Ulmus americana*), and many varieties of willow. The strawberry, raspberry, currant, plum, cherry, and grape are indigenous.

The climate of Manitoba, being that of a region of wide extent and of similar conditions, is not subject to frequent variations. Winter, with cold but clear and bracing weather, usually sets in about the middle of November, and ends with March. In April and May the rivers have opened, the snow has disappeared, and the opportunity has been afforded the farmer of sowing his grain. The month of June is often wet, but most favourable for the springing crops; July and August are warm, but, excepting two or three days at a time, not uncomfortably so; while the autumn months of August and September are very pleasant. Harvest generally extends from the middle of August to near the end of September. The chief crops of the farmer are wheat (which from its flinty hardness and full kernel is the specialty of the Canadian north-west), oats, barley, and pease. Hay is made of the native prairie grasses, which grow luxuriantly. From the richness and mellowness of the soil potatoes and all tap-roots reach a great size. Heavy dews in summer give the needed moisture after the rains of June have ceased. The traveller and farmer are at times annoyed by the mosquito. This troublesome insect is chiefly found near swampy ground or on the uncultivated prairie. It usually continues through June and July.

The population of the province is very mixed. In 1870 there were 2000 whites and 10,000 Indian half-breeds. Of the latter, one half are of English-speaking parentage, and chiefly of Orkney origin; the remainder are known as Metis or Bois-brûlés, and are descended from French-Canadian voyageurs. In 1875 a number of Russian Mennonites (descendants of the Anabaptists of the Reformation) came to the country. Some fifty years ago they originally emigrated from Germany to the plains of southern Russia, but came over to Manitoba to escape the conscription. They number nearly 8000. About 4000 French Canadians, who had emigrated from Quebec to the United States, have also made the province their home, as well as a number of Icelanders. The remainder of the population is chiefly made up of English-speaking people from the other provinces of the Dominion, from the United States, from England and Scotland and the north of Ireland. Though somewhat difficult to estimate, the population of Manitoba is estimated by competent authorities at upwards of 120,000 in 1882.

In 1881 the religious opinions of the people were as follows:—Episcopalians, 22 per cent; Presbyterians, 22; Roman Catholics, 19; Methodists, 14; Baptists, 2½; Lutherans, 1½ per cent.

There is a system of primary and secondary free school education for Protestants, and another for Roman Catholics. For the higher education there are the three colleges of St Boniface (Roman Catholic), St John's (Episcopalian), and Manitoba College (Presbyterian). These are affiliated to the university of Manitoba, which is an examining and degree-conferring body.

Like other provinces of the Dominion, Manitoba is under a lieutenant-governor, with a council of five ministers responsible to the local legislature, which again is composed of thirty-one members. The province is represented by three senators in the Dominion senate, and by five members in the Dominion house of commons. There are three judges of the superior court, and a number of county court judges. The whole province is divided into municipalities, each of which chooses a warden and six councillors annually.

The city of Winnipeg, the provincial centre of government, law, education, and religion, had in 1882 upwards of 20,000 inhabitants. The trade of the country has chiefly grown up since Winnipeg was connected in 1878 with the United States railroad system, and it has received a further impulse from the construction of the Canadian Pacific Railway, which traverses the territory. (G. BR.)

MANITOWOC, a city of the United States, the county seat of Manitowoc county, Wisconsin, is situated on the west side of Lake Michigan, at the mouth of Manitowoc river, 77 miles north of Milwaukee by the Milwaukee, Lake Shore, and Western Railway. It has a good harbour, and is the seat of an active trade in lumber, leather, and wheat. Shipbuilding is also extensively carried on. Population in 1870, 3059; in 1880, 6367.

MANKATO, a city of the United States, the county seat of Blue Earth county, Minnesota, is situated in the midst of a good agricultural district on the right bank of the Minnesota river, and is a station on the Chicago, Milwaukee, and St Paul, the Chicago and North Western, and the Chicago, St Paul, Minneapolis, and Omaha railways. From St Paul it is distant 86 miles. Besides carrying on an extensive trade Mankato manufactures woollen goods, linseed oil, flour, beer, carriages and waggons, iron wares, and furniture. It has a fine park and fair ground, three public halls, a public library, and a State normal school. The population increased from 3482 in 1870 to 5550 in 1880.

MANLEY, Mary de la Rivier (1672–1724), dramatist, political writer, and novelist, the most eminent female "wit" of the reign of Queen Anne, was the daughter of a studious and literary royalist, Sir Roger Manley, governor of the Channel Islands, part author of *The Turkish Spy*, and author of several military histories. Mrs Manley is herself the chief authority for such particulars of her private life as are known. Towards the close of Anne's reign, finding that Curll had announced *The Adventures of Rivella, or the History of the Author of Atalantis*, and suspecting this to be the work of an enemy, she contrived with dexterous tact to supplant Curll's author, and wrote her own biography under the announced title. Her mother died when she was a child, her father when she was a girl

of sixteen. A kinsman, already married, took advantage of her position, went through a mock ceremony of marriage, and deserted her basely three years afterwards. She was patronized for a short time by the duchess of Cleveland, and in 1696 made good a position among writers of established reputation by two plays, a comedy and a tragedy. The dialogue of the comedy, *The Lost Lover*, is extremely brilliant and witty, overflowing with high animal spirits; in freedom of speech it goes almost beyond the most licentious male writers of comedy in that generation. The play was at once published. In the preface she thanks the town for not keeping her long in suspense: her comedy was damned with promptitude. A similar fate befel her tragedy, *The Royal Mischief*, though great literary power was shown in it. The splendid energy of the characters, and the hyperbolical vigour of their language, may be compared with the undisciplined youth of the Elizabethan drama; but it was not without reason that even contemporary critics complained of the "warmth" of certain passages. She pleaded in defence the example of Dryden; but Dryden in his most indecent moments falls short of it. From 1696 Mrs Manley was a favourite member of witty and fashionable society; she admits that she never had any pretensions to beauty, but the charms of her eyes and her conversation made her very fascinating. She achieved her principal triumph as a writer by her *Secret Memoirs of Several Persons of Quality*, a scandalous chronicle "from the New Atalantis, an island in the Mediterranean," published in 1709. Henceforth she was known as "the author of *Atalantis*." The *Atalantis* had a political purpose. Mrs Manley was a warm Tory partisan, and she sought in this scandalous narrative to expose the private vices of the ministers whom Swift, Bolingbroke, and Harley combined to drive from office. There are many references to her in Swift's *Journal to Stella*. "She has very good principles for one of her sort, and a great deal of good sense and invention." Mrs Manley was in fact one of the most romantically public-spirited and disinterested politicians of that corrupt time, and next to Swift the most effective writer on the side of Harley and Bolingbroke. During the keen political campaign in 1711 she wrote several pamphlets, and many numbers of the *Examiner*, criticizing persons and policy with equal vivacity. After the accession of George, she wrote a tragedy *Lucius* (1717)—a failure, and two so-called novels, *Bath Intrigues*, and *A Stage-Coach Journey to Exeter*. The story in these novels is told in letters between the principal characters.

MANLIUS is the name of a Roman gens, chiefly patrician, but, in later times at least, also containing plebeian families. The Roman historians represent them as intrepid, but stern even to cruelty.

I. Marcus Manlius Capitolinus, a brave and distinguished soldier, was one of the garrison of the Capitol while besieged by the Gauls; when they attempted to scale the rock by night, Manlius, aroused by the cackling of the sacred geese, rushed to the spot and threw down the foremost. Several years after, seeing a centurion led to prison for debt, he freed him with his own money, and even sold his estate to relieve other poor debtors, while he accused the senate of embezzling public money. He was charged with aspiring to kingship, and condemned by the comitia, but not until the assembly had adjourned to a place without the walls, where they could no longer see the Capitol which he had saved. His house on the Capitol was razed, and the Manlii resolved that no patrician Manlius should henceforth bear the name of Marcus.

II. Titus Manlius Imperiosus Torquatus went to the tribune Pomponius, who had brought his father to trial for overstepping the limits of his office, and threatened to kill him unless he desisted from the accusation (365 B.C.) Shortly after he slew a gigantic Gaul in single combat, and took from him a torques or neck-ornament, whence his surname is said to have been derived. When the Latins demanded an equal share in the government of the confederacy, Manlius vowed to kill with his own hand the first Latin he saw in the senate-house. The Latins and Campanians revolted, and Manlius, consul for the third time, marched into Campania and gained two great victories, near Vesuvius (where Decius his colleague devoted himself to gain the day), and at Trifanum. In this campaign Manlius executed his own son, who had killed an enemy in single combat, and thus disobeyed the express command of the consuls.

Both these Manlii belong to a great extent to legend, much of which is probably due to attempts to explain their surnames.

III. Titus Manlius Torquatus in his first consulship (235 B.C.) subjugated Sardinia, recently acquired from the Carthaginians; he was consul again (224) during the Gallic war. In 216 he opposed the ransoming of the Romans taken prisoners at Cannæ; and in 215 he was sent to Sardinia and defeated a Carthaginian attempt to regain possession of the island.

IV. Cnæus Manlius Vulso, consul in 189 B.C., received Asia as his province. Starting from Ephesus in the spring, he marched into Pamphylia, levying enormous contributions. He then attacked the Celts of Galatia on the pretext that they had aided Antiochus. They took refuge in Mounts Olympus and Magaba, but the missiles of the Roman light troops won each position with great slaughter. In the winter, assisted by ten delegates sent from Rome, he settled the terms of peace with Antiochus. He returned to Rome in 187, and triumphed after much opposition. The discipline of his army was loose, and his soldiers brought into Rome many foreign luxuries.

MANN, Horace, one of the best-known of American educationists, was born at Franklin, Massachusetts, May 4, 1796, and died at Yellow Springs, Ohio, August 2, 1859. His childhood and youth were passed in great poverty. "It was the misfortune of his family that it belonged to the smallest district, had the poorest schoolhouse, and employed the cheapest teachers, in a town which was itself small and poor." His health was early injured by hard manual labour, which left him no time for recreation either in summer or winter. He lost his father at the age of thirteen. He was from his childhood an eager reader; but his only means of gratifying this desire was a very small library in his native town. Up to the age of fifteen he had never been able to attend school for more than eight or ten weeks in any one year. He remained at home, working for his mother and the rest of the family, till the age of twenty. At that age he was taught the rudiments of Latin and Greek and a little English grammar by an itinerant schoolmaster, and entered the junior classes in Brown University in the year 1816. Symptoms of consumption, poverty, the necessity of supporting himself while at college, and other circumstances interfered with his studies. He, however, graduated in 1819. In 1821 he entered the school of law at Litchfield, Connecticut, and was called to the bar in 1823. In 1827 he was elected to the State legislature of Massachusetts, and in 1833 he was returned to the upper house. He suggested and organized the State lunatic asylum of Worcester. In 1837 the legislature appointed a board of education to revise and reorganize the common school system of the State; and Mann was appointed secretary. To give his whole time to the work, he gave up his profession and also his seat in the senate. He was secretary for twelve years. For these twelve years he worked fifteen hours a day, held teachers'

conventions, gave lectures, and carried on an enormous correspondence. He started a periodical, *The Common School Journal*, in which he explained his views on education. He also published a series of *Annual Reports*; these American critics call "a classic on the subject." His seventh annual report gave the substance of his observations in Europe, and compared the systems of instruction followed in Prussia with those in use in Massachusetts, much to the disadvantage of the latter.[1]

In 1848 Mann was elected to Congress to fill the vacancy caused by the death of John Quincy Adams. He tried to induce the Government to establish a bureau of education at Washington, but this was not done till much later. He resigned his seat in Congress in 1853, and became the first president of Antioch College, at Yellow Springs,—a college for the combined education of men and women. Mann's chief work in American education is the reform which he brought about in the common and normal school system of Massachusetts; and this reform is largely due to his twelve annual reports.

Mann's other works are—*Lectures on Education*, 1848; *A Few Thoughts for a Young Man*, 1850; *Slavery, Letters and Speeches*, 1851; *Powers and Duties of Women*, 1853, &c. A complete edition of his writings, with a biography, was published in Cambridge, Massachusetts, in 1867; and a selection, under the title of *Thoughts Selected from the Writings of Horace Mann*, in 1869.

MANNA, a concrete saccharine exudation obtained by making incisions in the trunk of the flowering or manna ash tree, *Fraxinus Ornus*, L. At the present day the manna of commerce is collected exclusively in Sicily from cultivated trees, chiefly in the districts around Capaci, Carini, Cinisi, and Favarota, small towns 20 to 25 miles west of Palermo, and in the townships of Geraci, Castelbuono, and other places in the district of Cefalù, 50 to 70 miles east of Palermo. In the *frassinetti* or plantations the trees are placed about 7 feet apart, and after they are eight years old, and the trunk at least 3 inches in diameter, the collection of manna is begun. This operation is performed in July or August during the dry weather, by making transverse incisions 1½ to 2 inches long, and about 1 inch apart, through the bark, one cut being made each day, the first at the bottom of the tree, another directly above the first, and so on. In succeeding years the process is repeated on the untouched sides of the trunk, until the tree has been cut all round and exhausted. It is then cut down, and a young plant arising from the same root takes its place. The finest or flaky manna appears to have been allowed to harden on the stem. A very superior kind, obtained by allowing the juice to encrust pieces of wood or straws inserted in the cuts, and called *manna a cannolo*, is not found in commerce in England. The fragments adhering to the stem after the finest flakes have been removed are scraped off, and form the small or Tolfa manna of commerce. That which flows from the lower incisions is often collected on tiles or on a concave piece of the prickly pear (*Opuntia*), but is less crystalline and more glutinous, and is less esteemed.

Manna of good quality dissolves at ordinary temperatures in about 6 parts of water, forming a clear liquid. Its chief constituent is mannite or manna sugar, a hexatomic alcohol, $C_6H_8(OH)^6$, which likewise occurs, in much smaller quantity, in certain species of *Fucus* and in plants of several widely separated natural orders. Of this substance the best manna contains 70 to 80 per cent. It crystallizes in shining rhombic prisms from its solution in boiling alcohol. Manna possesses mildly laxative properties, and on account of its sweet taste is employed as a mild aperient for children. It is less used in England now than formerly, but is still largely consumed in South America. In Italy mannite is prepared for sale in the shape of small cones resembling loaf sugar in shape, and is frequently prescribed in medicine instead of manna.

The manna of the present day appears to have been unknown before the 15th century, although a mountain in Sicily with the Arabic name Gibelman, *i.e.*, "manna mountain," appears to point to its collection there during the period that the island was held by the Saracens, 827–1070. In the 16th century it was collected in Calabria in Italy, and until recently was produced in the Tuscan Maremma, but neither from that locality nor from the States of the Church is any now brought into commerce, although the name of Tolfa, a town near Civita Vecchia, is still applied to an inferior variety of the drug.

Various other kinds of manna are known, but none of these have been found to contain mannite. Alhagi manna (Persian and Arabic *tar-angubín*) is the produce of *Alhagi camelorum*, Fisch., a small, spiny, leguminous plant, growing in Persia, Afghanistan, and Baluchistan. This manna occurs in the form of small, roundish, hard, dry tears, varying from the size of a mustard seed to that of a coriander, of a light-brown colour, sweet taste, and senna-like odour. The spines and pods of the plant are often mixed with it. It is collected near Kandahar and Herat, and imported into India from Cabul and Kandahar to the extent of about 2000 lb. annually, and is valued at about thirty shillings per lb. Tamarisk manna (Persian *gaz-angubín*, tamarisk honey) exudes in June and July from the slender branches of *Tamarix gallica*, var. *mannifera*, Ehrenb., in the form of honey-like drops, which, in the cool temperature of the early morning, are found in the solid state. This secretion is caused by the puncture of an insect, *Coccus manniparus*, Ehrenb. In the valleys of the peninsula of Sinai, especially in the Wády el-Sheikh, this manna (Arabic *man*) is collected by the Arabs and sold to the monks of St Catherine, who supply it to the pilgrims visiting the convent. It is found also in Persia and the Punjab, but does not appear to be collected in any quantity. This kind of manna seems to be alluded to by Herodotus (vii. 31). Under the same name of *gaz-angubín* there are sold commonly in the Persian bazaars round cakes, of which a chief ingredient is a manna obtained to the south-west of Ispahan, in the month of August, by shaking the branches or scraping the stems of *Astragalus florulentus* and *A. adscendens*, Boiss. and Haussk.[2] *Shirkhist*, a kind of manna known to writers on materia medica in the 16th century, is still found in the bazaars of north-west India, being imported from Afghanistan and Turkestan to a limited extent. Haussknecht states that it is the produce of *Cotoneaster nummularia*, Fisch. and Mey. (*Rosaceæ*), and *Atraphaxis spinosa*, L. (*Polygonaceæ*), and that it is brought chiefly from Herat.

Oak manna, according to Haussknecht, is collected from the twigs of *Quercus Vallonea*, Kotschy, and *Q. persica*, Jaub. and Spach, on which it is produced by the puncture of an insect during the month of August. This manna occurs in the state of agglutinated tears, and forms an object of some industry among the wandering tribes of Kurdistan at the present day. It is collected before sunrise, by shaking the grains of manna on to linen cloths spread out beneath the trees, or by dipping the small branches in hot water and evaporating the solution thus obtained. A substance collected by the inhabitants of Laristan from *Purus glabra*, Boiss., strongly resembles oak manna in appearance.

Australian manna is found on the leaves of *Eucalyptus viminalis*, Lab.; the Lerp manna of Australia is of animal origin.

Briançon manna is met with on the leaves of the common Larch (*q.v.*), and a kind of manna was at one time obtained from the cedar, but none of these are now collected for commercial purposes.

The manna of Scripture, notwithstanding the miraculous circumstances which distinguish it in the Biblical narrative from anything now known, answers in its description very closely to the tamarisk manna.

See *Pharmacographia*, p. 409; Hanbury, *Science Papers*, p. 355–368; Stewart, *Punjab Plants*, Lahore, 1869, pp. 57–92; Geoffroy, *Mat. Med.*, ii. (1741) p. 584; Dobson, *Proc. Roy. Soc. Van Diemen's Land*, i. (1851) p. 234.

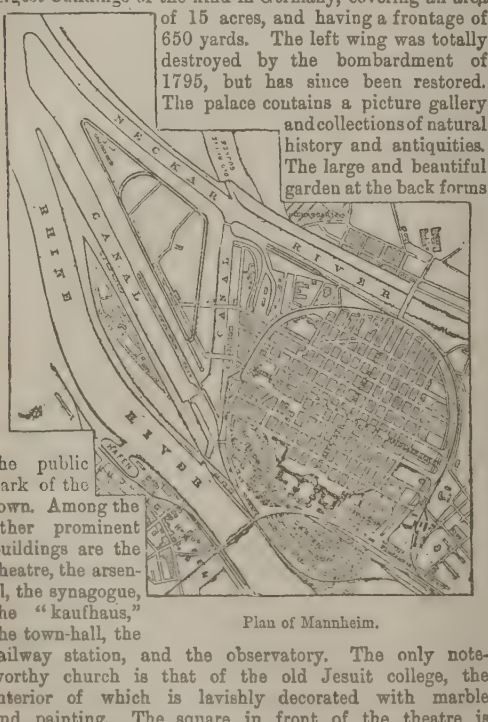
MANNHEIM, the most populous town and the second capital of the grand-duchy of Baden, lies on the right bank of the Rhine, in the triangular piece of low-lying ground enclosed between that river and the Neckar. It

[1] This report has been published and edited, with preface and notes, by Dr W. B. Hodgson, under the title of *Report of an Educational Tour in Germany, France, Holland, and parts of Great Britain and Ireland*, London, 1846.

[2] See *Bombay Lit. Tr.*, vol. i. art. 16, for details as to the gaz-angubín. A common Persian sweetmeat consists of wheat-flour kneaded with manna into a thick paste.

is the most regularly built town in Germany, consisting of twelve parallel streets intersected at right angles by ten others, which cut it up into about 130 square sections of equal size. These blocks are distinguished, after the American fashion, by letters and numerals. Except on the south side all the streets debouch on the promenade, which forms a circle round the town on the site of the old ramparts. Outside this ring are the suburbs of Schwetzinger Gärten to the south and Neckargärten to the north. Mannheim is connected by a handsome bridge with Ludwigshafen, a rapidly growing commercial and manufacturing town on the left bank of the Rhine, in Bavarian territory. The Neckar is spanned by a suspension bridge. In 1880 Mannheim contained 53,545 inhabitants, of whom about 4500 were Jews, and the rest Roman Catholics and Protestants in nearly equal proportions. Ludwigshafen contained 15,012 inhabitants.

Nearly the whole of the south-west side of the town is occupied by the palace, built in 1720–29, and formerly the residence of the elector of the Palatinate. It is one of the largest buildings of the kind in Germany, covering an area of 15 acres, and having a frontage of 650 yards. The left wing was totally destroyed by the bombardment of 1795, but has since been restored. The palace contains a picture gallery and collections of natural history and antiquities. The large and beautiful garden at the back forms the public park of the town. Among the other prominent buildings are the theatre, the arsenal, the synagogue, the "kaufhaus," the town-hall, the railway station, and the observatory. The only noteworthy church is that of the old Jesuit college, the interior of which is lavishly decorated with marble and painting. The square in front of the theatre is embellished with statues of Schiller, Iffland the actor, and Dalberg, intendant of the theatre in the time of Schiller. Mannheim is the chief commercial town on the upper Rhine, and yields in importance to Coblentz and Cologne alone among the lowei Rhenish towns. The staple commodities of its trade are tobacco, grain, petroleum, hops, timber, and coffee. Its new harbour, constructed at a cost of £650,000, and measuring 2300 yards in length, is the most extensive inland harbour in Germany. It is entered annually by 3000 river craft, carrying nearly 700,000 tons of goods. The railway goods station and warehouses in connexion with the harbour cover 400 acres of ground. The principal industrial products of Mannheim are machinery, iron, brass, india-rubber, sugar, mirrors, chemicals, wall-paper, and cigars. The manufactories of Ludwigshafen produce aniline dyes, soda, tartaric acid, alum, artificial manures, and lime. Mannheim is the seat of the central board for the navigation of the Rhine, of a chamber of commerce, and of the supreme court of Baden. Ten or twelve different countries are represented here by their consuls. The schools and public institutions of Mannheim include a gymnasium, a "realschule," an industrial school, a high school for girls, a public library, a large poorhouse, three hospitals, and an orphanage.



Plan of Mannheim.

*History.*—The name of Mannheim was connected with its present site as early as the 8th century, when a small village belonging to the abbey of Lorsch lay in the marshy district between the Neckar and the Rhine. To the south of this village, on the Rhine, was the castle of Eicholzheim, which acquired some celebrity as the place of confinement assigned to Pope John XXIII. by the council of Constance. The history of the modern Mannheim begins, however, with the opening of the 17th century, when Elector John Frederick IV. founded a town here, which he peopled chiefly with Protestant refugees from Holland. The strongly fortified castle which he erected at the same time had the unfortunate result of making the infant town an object of contention in the Thirty Years' War, during which it was five times taken and retaken. In 1689 Mannheim, which had in the meantime recovered from its former disasters, was captured by the French under Melac, and ruthlessly destroyed. Ten years later it was rebuilt on an extended scale and provided with fortifications. For its subsequent importance it was indebted to Elector Charles Philip, who, owing to ecclesiastical disputes, transferred his residence from Heidelberg to Mannheim in 1720. It remained the capital of the Palatinate for nearly sixty years. In 1794 Mannheim fell into the hands of the French, and in the following year it was retaken by the Austrians after a severe bombardment, which left scarcely a single building uninjured. In 1802 it was assigned to the grand-duke of Baden, who caused the fortifications to be razed. Ludwigshafen, originally only the *tête-du-pont* of Mannheim, received its present name in 1843, and became a town in 1859. Towards the end of last century Mannheim attained great celebrity in the literary world as the place where Schiller's early plays were performed for the first time. It was at Mannheim that Kotzebue was assassinated in 1819.

See Feder, *Geschichte der Stadt Mannheim*, 1875: and Unglenk, *Praktischer Führer durch Mannheim*, 1880.

MANNING, Robert, commonly known as Robert of Brunne, a monk of the priory of Brunne or Bourne in Lincolnshire, wrote in the beginning of the reign of Edward III. a metrical history of England from the landing of the imaginary Brute to the end of the reign of Edward I. The work has no independent historical value; it professedly follows Peter of Langtoft's *Chronicle* from the Anglo-Saxon or "Inglis" invasion downwards, and Wace for the previous "British" story. It is a lively narrative, written "not for the lered bot for the lewed," and it has a certain interest as a landmark, not only in the history of the English language, but also in the history of national sentiment. Manning is warm in praise of the deeds and the character of Edward I., "Edward of Inglond," although he deplores the Norman Conquest as a "bondage," and says concerning the death of Harold that "our freedom that day for ever took the leave." The old monk is our first avowedly "popular" historian. He wrote for the entertainment of men who knew neither Latin nor French, and in his prologue comments humorously on the "quaint English" and subtle rhymes of his predecessors, claiming for himself purity of language and simplicity of metre. A passage in this prologue has often been quoted as bearing on the authorship of the romance of *Sir Tristram*. Manning also translated William of Waddington's *Manuel des Pechiez* under the title of *Handlyng Synne*, in 1303, and is plausibly conjectured to be the author of *Medytacyuns of the Soper of oure Lorde Ihesu*, translated from Bonaventura's *Vitæ Christi*. He is not a bald rhymester, but uses language with skill and effect, and in some places where he departs from his originals shows genuine poetical rapture.

MANOMETER, or Pressure Gauge, is an instrument for measuring the hydiostatic pressure exerted by gases,

vapours, or liquids against the sides of the closed vessels in which they are confined,—as, for instance, the pressure of steam in a steam-boiler.

The simplest and at the same time most accurate form of manometer is that known as the "mercury manometer," sometimes also called the "free-air manometer," and represented in fig. 1. It consists essentially of two vertical communicating tubes. One of these, AB, open at both ends, and made of thick glass, with a narrow uniform bore, is fixed hermetically in the neck of a large wrought-iron cylinder C, its lower end dipping below the surface of mercury contained in the cylinder. The other tube, EF, is attached at its lower end to the cylinder by the cross pipe D, and at its upper end can be put in communication with the vessel the pressure in which is to be ascertained. Usually the tube EF, the cross pipe D, and the space above the mercury in C are filled with water. At first the tube EF is left open to the atmosphere, and the height of the mercury in AB noted. When EF is then put in communication with the vessel in which the pressure (above atmospheric) is to be determined, the mercury in AB rises, and from the height to which it rises the pressure is deduced. For accurate work corrections must be made for the fall of the mercury in C as it rises in AB, and for the temperature and the height of the barometer at the time of the experiment.

FIG. 1.—Mercury Manometer.

The great drawback to the employment of the simple mercury manometer for measuring very great pressures is the mechanical difficulty of obtaining a sufficiently long column of mercury. E. H. M. Amagat, however, has lately (1880) worked with a column *one-fifth of a mile* high. His experiments were undertaken to find out how the various gases, nitrogen, oxygen, air, hydrogen, &c., departed from Mariotte's law when subjected to enormous pressures. At the bottom of a coal-mine at Verpilleux, near St Étienne, which had a depth of 327 metres, was placed the glass manometer tube containing the compressed gas, while the mercury tube (made of steel) extended up the shaft, being gradually built up in sections. See *Nature*, vol. xxii. pp. 62, 63. By means of Amagat's tables of the volume and corresponding pressure of the several gases, and with special forms of manometer to suit particular circumstances, accurate and delicate measures of enormous pressures can now be obtained. Professor Tait, for instance, has recently applied these tables along with a manometer of his own devising for testing the behaviour of the thermometers supplied to the "Challenger" expedition under a pressure of as much as 10 tons to the square inch.

"Regnault's manometer" is shown in fig. 2. AB is a strong metal tube, closed at the lower end, and carrying at the upper a bent pipe for admitting the compressed gas and a stop-cock R pierced with holes in a T form. DE and FG are two graduated glass tubes communicating at their lower ends by a narrow passage in the metal block to which they are hermetically fixed. DE and AB also communicate at the upper ends by a passage in a metal piece attached hermetically to them. By the stop-cock R′, having radial holes at right angles to each other, DE can communicate either with AB or with the atmosphere at O; and by the stop-cock R″ it can communicate either with FG or with the open air. The three tubes are surrounded by a cylinder MM′ containing water to keep the temperature constant. The tube AB is filled with the compressed gas whose pressure is to be ascertained. The stop-cock R′ being then placed as in fig. 2, mercury is poured into FG till it fills DE and runs out at O. The stop-cocks R and R′ are then turned as in fig. 2*a*, so that AB and DE communicate with each other. Part of the compressed gas flows over into DE, and the mercury in FG rises. By manipulating the stop-cock R″ as shown in fig. 2*b*, part of the mercury is allowed to run out of DE till a conveniently measurable difference of level between the mercury surfaces in DE and FG is attained.

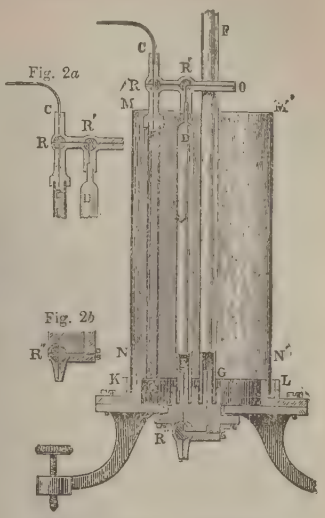


FIG. 2.—Regnault's Manometer.

Let $h$ be this difference. Also let $x$ be the pressure of the gas originally filling the volume V of AB, V′ the additional volume occupied by the expanded gas, and H be the height of the barometer at the time; then we have by Mariotte's law

$$xV=(V+V')(H+h),$$

from which

$$x=\frac{V+V'}{V}(H+h) \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

V′ is determined by weighing the mercury required to fill the space it occupies, and V can be calculated from (1) when AB is filled with dry air at pressure H.

In Regnault's apparatus the length of AB and DE was 1 metre, the diameter of AB 5 mm. and of DE 20 mm. The section of DE was thus sixteen times that of AB, and in this way a very great pressure could be measured by a comparatively small difference of level between the mercury surfaces in FG and DE. The instrument, however, is subject to errors, arising chiefly from the difficulty of measuring accurately the volumes V and V′.

The "compressed air manometer" (fig. 3) consists of a strong graduated glass tube of uniform narrow bore, closed at the top and fixed hermetically into the neck of a wide iron cylinder. The tube contains dry air, and its lower end dips below the surface of mercury contained in the cylinder. Attached to the side of the cylinder is a tube A, with a stop-cock, to afford communication with the vessel the pressure in which is to be measured. When the manometer is attached to the vessel containing compressed gas the mercury rises in the glass tube till the pressure of the air confined in the tube (reckoned in millimetres of mercury) plus the height of the mercury column above the level of the mercury in the cylinder is equal to the pressure on the surface of mercury in the cylinder.

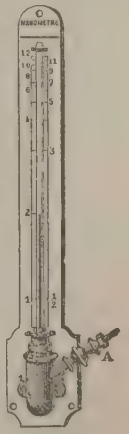

FIG. 3.—Compressed Air Manometer.

"Desgoffe's manometer" depends upon the same principle as the hydraulic press, and can be employed to measure the enormous pressure reached in the cylinder of that instrument. It is represented in perspective in fig. 4 and in section in fig. 5. V is a strong circular iron vessel, in which moves up and down for a short distance a flat piston D attached to a cylindrical plug T. The lower part of V contains mercury which has free communication with a graduated vertical glass tube AB fixed hermetically into the side of V. Above the mercury in V is placed a thin layer of water, and above that is stretched a thin membrane of india-rubber bolted down water-tight by an iron ring. The chamber C contains a cavity in which the plug T moves water-tight. By means of the tube *t* the instrument can be put in communication

with the vessel containing the fluid whose pressure is to be measured. The compressed fluid acting upon T depresses the piston D and causes the mercury to rise in AB.

Let $p$ be the pressure of the fluid per unit of area, $s$ the area of T, and S the area of D; also let P be the pressure per unit of area as recorded by the height of the mercury in AB. Thus evidently we have $ps = PS$, or $p = \frac{S}{s}P$.

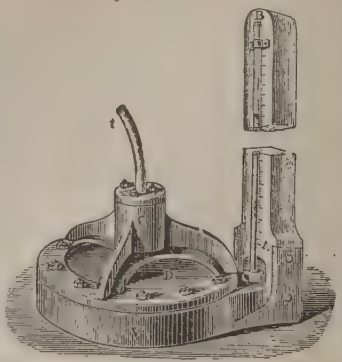

FIG. 4.—Desgoffe's Manometer.

Hence by making S very great and $s$ very small a very great pressure can be measured by a comparatively short column of mercury in AB. As part of the pressure $p$ is employed to stretch the india-rubber membrane, the ratio $S:s$ should be made very great, so that D will only sink a very short distance. Cailletet, who employed this manometer in his experiments on the compressibility of fluids, had it so arranged that (neglecting the stretching of the india-rubber) the mercury in AB rose 4·3 metres while the piston in D sunk only one-eighth of a millimetre.

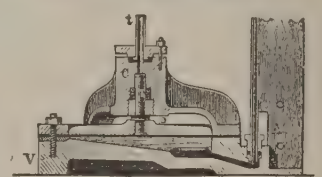

FIG. 5. Section of Desgoffe's Manometer.

Metallic manometers depend on the principle exemplified in the aneroid barometer. Suppose a long tube, preferably of elliptic section, and having thin walls of elastic material, to be closed at one end and either bent or coiled up in the form of a spiral. Let the open end be attached to an apparatus whereby the pressure inside the tube can be either increased or diminished. If the pressure inside the tube be made greater than that outside, the tube has a tendency to straighten or uncoil itself, but if the pressure outside be greater than that inside the tube has a tendency to bend or coil itself up farther. Fig. 6 represents an early form of metallic manometer made on this principle by Bourdon, the first to construct such instruments. A metallic tube $ab$, closed at $b$, is coiled in a spiral and rigidly attached at the open end $a$ to a tube with stop-cock $m$, whereby it can communicate with the compression apparatus. A light index $e$ is attached to $b$ and moves over a graduated scale. The scale is graduated by applying known pressures inside the tube. This form of manometer is very convenient for rough practical work, but has no pretensions to scientific accuracy, as changes of temperature affect the elasticity of the tube in a way which is difficult to discover and allow for. Various forms of metallic manometers have been recently invented, the best-known of which are perhaps those of Bourdon and Schäfer, in which the index is moved by a train of wheels actuated by the free end of the elastic tube.

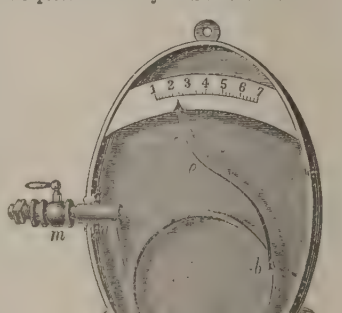

FIG. 6.—Bourdon's Metallic Manometer.

*Air-pump Manometer.*—For measuring pressures less than that of the atmosphere, as in the receiver of an air-pump, a special form of mercury manometer is employed, consisting of a glass U tube with each leg over 30 inches long and half filled with mercury. One leg communicates by an air-tight communication with the receiver of the air-pump, and the other is left open. As the exhaustion proceeds, the mercury falls in the open leg and rises in the other. When only considerable degrees of exhaustion are to be measured, the instrument takes the form of a short U tube closed at one end and open at the other, and has its closed leg completely filled with mercury, the mercury being held up by the atmospheric pressure. The whole is enclosed in a wide glass tube closed at the top and hermetically fixed at the lower end to a brass piece, provided with a stop-cock, whereby it can be screwed on to the sole plate of the air-pump. The difference of level in the two legs gives the degree of exhaustion obtained.

See Ganot's *Physics*; Wüllner's *Lehrbuch der Experimentalphysik*; Amagat in *Annales de Chemie et de Physique*, March 1880; *Report of H.M.S. Challenger*, in regard to pressure corrections supplied by thermometers, by Professor Tait. (J. Bl.)

MANOR, in English law, is an estate in land, to which is incident the right to hold certain courts called courts baron. It might be described as the unit of tenure under the feudal system, and it is historically connected with the territorial divisions of the mark and the parish or township.[1] The legal theory of the origin of manors refers them to a grant from the crown, as stated in the following extract from Perkins's *Treatise* on the laws of England:—"The beginning of a manor was when the king gave a thousand acres of land, or a greater or lesser parcel of land, unto one of his subjects and his heirs, which tenure is knight's service at the least. And the donor did perhaps build a mansion house upon parcel of the same land, and of 20 acres, parcel of that which remained, or of a greater or lesser parcel before the statute of *Quia Emptores* did enfeoff a stranger to hold of him and his heirs to plow 10 acres of land, parcel of that which remained in his possession, and did enfeoff another of another parcel thereof to go to war with him against the Scots, &c., and so by continuance of time made a manor." It is still, as Mr Joshua Williams terms it, a "fundamental rule" that all lands were originally derived from the crown, and that the queen is lady paramount mediate or immediate of all the land in the realm. A manor then arises where the owner of a parcel so granted or supposed to have been granted by the crown (and who is called in relation thereto the lord) has in turn granted portions thereof to others who stand to him in the relation of tenants. Of the portion reserved by the lord for his own use (his demesne) part was occupied by villeins, with the duty of cultivating the rest for the lord's use. These were originally tenants at will, and in a state of semi-serfdom, but they became in course of time the copyhold tenants of the later law. (See COPYHOLD.) It is of the essence of copyhold that it should be regulated by the custom of the manor; and that, according to some authorities, is one reason why a manor cannot be created at the present day. "Length of time being of the very essence of a manor, such things as receive their perfection by the continuance of time come not within the compass of a king's prerogative" (Scriven, *Copyholds*, chap. i.). But the effect of the statute of *Quia Emptores* was to make the creation of manors henceforward impossible, inasmuch as it enacted "that upon all sales or feoffments of land, the feoffee shall hold the same, not of his immediate feoffor, but of the chief lord of the fee of whom such feoffor himself held it." The statute did not apply to the king's tenants *in capite*, who might have aliened their land under a licence. Accordingly it is assumed that all existing manors are "of a date prior to the statute of *Quia Emptores*, except perhaps some which may have been created by the king's tenants *in capite* with licence from the crown" (Williams, *Real Property*, chap. iv.; see also Scriven, *Copyholds*, chap. i.). When a great baron had granted out smaller

[1] Laveleye (*Primitive Property*, chap. xviii.) observes that in the 10th century, even before the Norman Conquest, the mark had already been transformed into the manor, although the term was not yet in use. The country was covered with a great number of domains (*maneria*), of very different extent, from the maneriolum of one plough to the latifundium of fifty ploughs.

manors to others, the seignory of the superior baron was frequently termed an honour.

MANRESA, a town of Catalonia, Spain, 39 miles north-west of Barcelona, with a population of 15,264. It was formerly Bacasis, one of the cities of the Jaccetani, the most important of the small tribes at the foot of the Pyrenees. It lies on the left bank of the Cardonero, 2 miles above its junction with the Llobregat, in the midst of a fertile and well-irrigated district, and its chief manufactures are cloth, cotton, silk, gunpowder, and brandy. Building stone is quarried near the town. The Cardonero is crossed by two bridges,—one ancient, the other erected in 1804. The two principal sights of Manresa are the collegiate church, El Seo, commenced in 1328, and finished in the 15th century, and the Cueva de San Ygnacio. The late Mr G. E. Street has minutely described the church in his *Gothic Architecture of Spain*. Among its greatest treasures he specializes a magnificent altar frontal as "the most beautiful work of its age." It is 10 feet long by 2 feet 10 inches in height, and is divided into nine compartments, at the bottom of which is the inscription in Lombardic characters :—GERI : LAPI : RECHAMATORE : MEFECIT : INFLORENTIA. In the Cuevá de San Ygnacio, Ignatius Loyola lived for a year, fasting and submitting himself to the severest penances, constantly gazing at the shrine of the Virgin of Montserrat, who, he asserted, encouraged him in his austerities. A great monastery surrounds the cave, which is visited by thousands of pilgrims, and from the esplanade there is a magnificent view of the "pinnacles, spires, turrets, sugar-loaves, and pyramids of faint grey rocks," constituting the famous mountain of Montserrat. At Cardona, a little more than 20 miles to the north-west of Manresa, there is a remarkable hill of rock-salt 3 miles in circumference, and 350 feet in height, which is estimated to contain 400 million cubic yards of salt.

MANS, Le, a town of France, formerly capital of Maine and now of the department of Sarthe, lies 118 miles (131 by rail) W.S.W. from Paris, near the confluence of the Sarthe and the Huisne, on an elevation rising from the left bank of the former river. Three bridges besides that of the railway connect the town with the quarter on the right bank. Of the wide and commodious thoroughfares which are gradually superseding the old winding and narrow streets, the most worthy of notice is the tunnel by which the Place des Jacobins is connected with the river side. The principal building is the cathedral, originally founded by St Julian, to whom it is dedicated. Rebuilt in the 6th century by St Innocent, in the 9th by St Aldric, and a third or fourth time in the 11th by Vulgrin, who was at once architect and bishop, it was completed by the addition of two towers in the 12th. Destroyed by two fires, the roof was reconstructed in the Gothic style, and the transept and south portal were added. In the 13th century the choir was enlarged in the grandest and boldest style of that magnificent period. Finally a new transept and a bell tower were added in the 15th century. In the large window of the west front the ten divisions which have for their subject the legend of St Julian are the oldest extant specimens of stained glass in France (end of 11th century). The side portal (12th century) is richly decorated, and its statuettes exhibit many interesting costumes of the period. The aisles have ten bays, but the nave only five; the transept is much higher; from it rises the only tower of the building. The austere simplicity of the nave is in striking contrast with the lavish richness of the ornamentation in the choir and apse. The former is 115 feet in height, and has twelve chapels besides the sacristy; its windows almost entirely date from the middle of the 13th century. The glass of the north transept is of the 15th century, and represents the Last Judgment; it contains many historical figures. The cathedral has also curious tapestries and some remarkable tombs, including that of Berengaria, queen of Richard Cœur de Lion. The entire length of the building is 427 feet. Close to the western wall is a megalithic monument nearly 15 feet in height. The church of La Couture, which belonged to an old abbey founded in the 7th century by St Bertrand or Bertram, has a remarkable porch of the 13th century; the rest of the building is older. Of the other churches of Le Mans, none require special mention except that of Notre Dame du Pré, on the right bank of the Sarthe. Of the secular buildings may be mentioned the hôtel de ville, built about a century ago on the site of the former castle of the counts of Maine, and the prefecture, occupying the site of the monastery of La Couture (1760). The latter contains the library (50,000 volumes, 700 MSS.), the communal archives, and the museum of paintings, archæology, and natural history. Other prominent buildings are the general hospital, the lyceum, the seminary, the palais de justice, and the cavalry barracks; the house occupied by Scarron is still pointed out, and there are considerable remains of the old Gallo-Roman enceinte. The principal promenades are those of the Jacobins, of the horticultural garden, Du Greffier (on the right bank of the river), and Des Sapins (on the road to Tours). The industries of Le Mans, which are carried on chiefly in the faubourg of Pontlieue, include metal-working, the manufacture of agricultural implements, and weaving. For some years there has been a Government tobacco factory. A local specialty is the fattening of poultry. The population in 1876 was 50,175 (including 5282 representing the garrison, &c.). Le Mans is an important railway junction.

As the capital of the Aulerci Cenomani, Le Mans was called Suindinum or Vindinum. The Romans surrounded it with walls in the 3d century; it was evangelized by St Julian in the 4th. The countship of Maine was made hereditary by Hugh Capet in the 10th century. Le Mans was seized by William the Conqueror, but his son Robert was unable to retain it. Having chosen the side of Richard Cœur-de-Lion, it was taken by Philip Augustus, recaptured by John, subsequently confiscated, and afterwards ceded to the widow of Richard. Maine was next held by Margaret, the wife of St Louis, who gave it to his brother Charles of Anjou. Le Mans was five times besieged during the Hundred Years' War, and was subsequently devastated by the Huguenots in 1562. In 1793 it was seized by the Vendeans, who were expelled by Marceau after a sanguinary battle in the streets of the town. In 1799 it was again occupied by the Chouans; and in January 1871 the second army of the Loire sustained in the neighbourhood of Le Mans a defeat which made the relief of Paris impossible. The town is the birthplace of Henry II. of England, of John the Good, king of France, and of Chappe, the inventor of the aerial telegraph.

MANSEL, Henry Longueville (1820–1871), metaphysician and theologian, was born at Cosgrove, Northamptonshire (where his father was rector) in 1820, and educated at Merchant Taylors' School and St John's College, Oxford. He succeeded to a fellowship in 1842, graduated in 1843, and became tutor of his college. He was appointed reader in moral and metaphysical philosophy at Magdalen College in 1855, becoming Waynflete professor in 1859. In 1867 he succeeded Dean Stanley as professor of ecclesiastical history, and in the following year was appointed dean of St Paul's. He died July 31, 1871.

The philosophy of Mansel, like that of his older contemporary Sir W. Hamilton of Edinburgh, was mainly due to three sources,—the works of Aristotle, the speculations of Kant, and the philosophy of Reid. Like Hamilton, Mansel maintained the purely formal character of logical science, the duality of consciousness as testifying to both self and the external world, and the limitation of knowledge to the finite and "conditioned." His logical doctrines were developed in his edition of Aldrich's *Artis Logicæ Rudimenta* (1849)—his chief contribution to the reviving study of Aristotle—and in his *Prolegomena Logica,—an Inquiry into the Psychological Character of Logical Processes* (1851), in which the limits of logic as the "science of formal thinking" are rigorously determined. In his Bampton Lectures on *The Limits of Religious Thought* (1858)

he applied to Christian theology the metaphysical agnosticism which seemed to result from Kant's criticism, and which had been developed in Hamilton's *Philosophy of the Unconditioned*. Showing the contradictions which arise when we attempt to conceive God under the categories of substance or cause, Mansel contends that we can have no positive conception either of the metaphysical or moral attributes of the Absolute and Infinite Being, though we are compelled to believe in His existence, the religious consciousness being built up by reflexion from the feeling of dependence and the conviction of moral obligation. Hence he infers the invalidity of all objections to revelation from its alleged inconsistency with the Divine character, maintaining the dependence of its claim to acceptance upon the evidences accompanying it. While denying all knowledge of the supersensuous, Mansel deviated from Kant in contending that cognition of the ego as it really is is itself a fact of experience. Consciousness, he held,—agreeing thus with the doctrine of "natural realism" which Hamilton developed from Reid,—implies knowledge both of self and of the external world. The latter Mansel's psychology reduces to consciousness of our organism as extended; with the former is given consciousness of free-will and moral obligation. These views and a summary of his whole philosophy are contained in his article "Metaphysics" contributed to the 8th edition of the *Encyclopædia Britannica* (separately published, 1860). Mansel was also the author of an essay on *The Philosophy of the Conditioned* (1866) in reply to Mill's criticism of Hamilton, of other controversial and occasional writings republished in *Letters, Lectures, and Reviews* (1873), and of lectures on *The Gnostic Heresies* (edited by J. B. Lightfoot, 1875).

MANSFELD, Count Ernest of (1585–1626), a natural son of Peter Ernest, governor of Luxemburg and Brussels, was born in 1585. Trained by his godfather, the archduke Ernest of Austria, in the Roman Catholic religion, he devoted himself to the service of the king of Spain in the Netherlands, and to that of the emperor in Hungary. The emperor Rudolf II. conferred on him the rights of legitimate birth, and promised to put him in possession of his father's lands in the Netherlands. As this promise was not fulfilled, he joined the Reformed Church, and in 1610 formally associated himself with the Protestant princes. From the outbreak of the Thirty Years' War in 1618 he fought steadily on behalf of the elector of the Palatinate both in Bohemia and in the Rhine country. In 1625 he was able to collect a powerful force with which he intended to attack the hereditary territories of Austria, but, on the 25th of April 1626, he was defeated by Wallenstein at Dessau. He pressed forward to effect a junction with Bethlen Gabor, prince of Transylvania, but as the latter changed his policy Mansfeld had no alternative but to disband his army. When preparing to go to England by Venice, he became ill at a village near Zara, and died on the 20th of November 1626. He was a man of great courage and resource, and ranks among the most brilliant generals of his age.

See Reuss, *Graf Ernst von Mansfeld im böhmischen Kriege* 1618–21 (1865); Villermont, *Ernest de Mansfeld* (1866); and Graf Uetterodt zu Scharffenberg, *Ernest Graf zu Mansfeld, historische Darstellung* (1867).

MANSFIELD, a market-town in the county of Nottingham, England, is situated in Sherwood Forest, near the north bank of the river Mann or Maun, 17 miles north-west from Nottingham, and 140 north-north-west of London by rail. The town is built of stone, with regular streets radiating from the market place, and several good houses. The church of St Peter is partly Early Norman and partly Perpendicular. There is a grammar school founded by Queen Elizabeth in 1561, for which new buildings have lately been erected at a cost of £10,000. Twelve almshouses were founded by Elizabeth Heath in 1693, and to these six were afterwards added. In addition there are a number of other charities. The other principal buildings are the town-hall, the mechanics' institute, and the public baths. In the market place there is a monument to Lord George Bentinck. The industries of the town are the manufacture of lace thread, cotton hose, machines, engines, and bricks and tiles, iron-founding, and brewing. In the neighbourhood there are quarries of limestone, sandstone, and freestone. Population in 1871, 11,824; in 1881, 13,651.

From coins found at Mansfield and the remains of a Roman villa in the neighbourhood, it is believed to have been a Roman station. During the heptarchy it was occasionally the residence of the Mercian kings, and it was afterwards a favourite resort of Norman sovereigns. By Henry VIII. the manor was granted to the earl of Surrey. Afterwards it went by exchange to the duke of Newcastle, and from the Newcastles to the Portland family. The town obtained a fair from Richard II. in 1377.

MANSFIELD, the county seat of Richland county, Ohio, U.S., pleasantly situated on high ground, 54 miles south of Sandusky, in the midst of a prosperous farming district. It is the terminus of the North-Western Ohio Railroad, and is at the junction of the Baltimore and Ohio, the Pittsburgh, Fort Wayne, and Chicago, and the New York, Pennsylvania, and Ohio lines. It possesses a flourishing trade, and extensive manufactories of agricultural implements, machinery, flour, boilers, carriages, and household furniture, with many minor industries. Mansfield has public water-works on the "Holly" system, a public library, and an opera-house. The population was 8029 in 1870 and 9859 in 1880.

MANSFIELD, William Murray, Earl of (1705–1793), was born at Scone, in Perthshire, on 2d March 1705. He was the eleventh child and fourth son of David, fifth Viscount Stormont, a nobleman whose family possessions had shrunk within so narrow limits that he had to bring up his numerous family with exceedingly strict economy. The family was Jacobite in its politics, and the second son, being apparently mixed up in some of the plots of the time, joined the court of the Pretender at the accession of George I., and was created by him earl of Dunbar. William Murray was sent first to the grammar school at Perth, where he remained until he was thirteen, and at that age was sent to Westminster at the suggestion of his exiled brother, who had been in close relation with Atterbury (then dean of Westminster), and probably desired to bring the boy under his influence. He was elected a king's scholar a year after his entrance, and in 1723 was first on the list of scholars sent on the foundation to Christ Church, where he remained for nearly four years. It had been originally intended that he should enter the English church, as, although his own inclination while at school pointed strongly towards the bar, the circumstances of his family seemed to forbid the expense of a legal education. But this obstacle was removed by the kindness of the father of one of his schoolfellows, and he was entered at Lincoln's Inn. Soon after he went to Oxford. In 1727 he took chambers in Lincoln's Inn, and in 1730 was called to the bar. His studies from the time he left Westminster seem to have been steadily directed towards his future profession, but in a manner far more liberal than was then usual among lawyers. He had made himself at Westminster and Oxford an admirable classical scholar; he paid particular attention to English composition and to the art of debate; his historical studies were extensive, and in the more strictly professional sphere his wide view of the education necessary for a lawyer was shown by the knowledge he acquired of Roman law and of the juridical writers of Scotland and France. At the same time he enjoyed the advantage of mixing extensively with the best literary society. He had early become an intimate friend of Pope, and his own ability and accomplishments soon made him everywhere a man of mark.

For two or three years he made little or no progress at the bar, but at length his appearance in some important Scotch appeal cases brought him into notice, and in Scotland at least he acquired an immense reputation by his appearance for the city of Edinburgh when it was

threatened with disfranchisement for the affair of the Porteous mob. His English business had as yet been scanty, but in 1737 a single speech in a jury trial of note may be said to have placed him at the head of the bar, and from this time he enjoyed a great business. In 1738 he married Lady Elizabeth Finch, daughter of the earl of Winchelsea. His political career commenced in 1742 with his appointment as solicitor-general. Probably his political opinions were not of a marked party character; he had been bred a Jacobite, and many of his earlier associates belonged to the high Tory camp, but his calm sense and temper disinclined him to extreme factions, and indeed his interest in politics seems at all times to have been subordinate to the love of his profession. He had kept entirely aloof during the struggles which preceded the fall of Sir Robert Walpole; he refused any purely political appointment, and only took office as solicitor when he felt assured of the permanence of the new administration. During the next fourteen years Murray was one of the most conspicuous figures in the parliamentary history of the time. Although holding an office of subordinate rank, and not sharing, nominally at least, in the councils of the administration, he was the chief defender of their measures in the House of Commons, and during the time that Pitt was in opposition had to bear the brunt of his attacks. He was especially conspicuous in the great debates on the employment of the Hanoverian troops, the treaty of Aix-la-Chapelle, and the Regency Bill. In 1754 he became attorney-general, and for the next two years acted as leader of the House of Commons under the administration of the duke of Newcastle. During these years he had to defend a weak Government against the incessant, vehement assaults of Pitt, and, according to the testimony of contemporaries, acquitted himself brilliantly in the contest. But in 1756, when the Government was evidently approaching its fall, an unexpected vacancy occurred in the chief justiceship of the king's bench, and he claimed the office. Newcastle made every effort to retain him in the House of Commons, feeling as he did that his departure would hasten the fall of the Government, but Murray was inexorable. He seems to have been thoroughly tired of his parliamentary life, and to have long looked forward to the bench as the proper sphere of his work. He was at the same time raised to the peerage as Baron Mansfield.

From this time the chief interest of his career lies in his judicial work, but he did not wholly dissever himself from politics. He became by a singular arrangement, only once repeated subsequently in the case of Lord Ellenborough, a member of the cabinet, and remained in that position through various changes of administration for nearly fifteen years, and, although he persistently refused the chancellorship, he acted as speaker of the House of Lords while the great seal was in commission. During the time of Pitt's ascendency he took but little part in politics, but while Lord Bute was in power his influence was very considerable, and seems mostly to have been exerted in favour of a more moderate line of policy. He was on the whole a supporter of the prerogative, but within definite limits. Macaulay terms him, justly enough, "the father of modern Toryism, of Toryism modified to suit an order of things in which the House of Commons is the most powerful body in the state." In this spirit he continued to act a conspicuous though not a foremost part in political life during the rest of his career. During the stormy session of 1770 he came into violent collision with Lord Chatham and Lord Camden in the questions that arose out of the Middlesex election and the trials for political libel, and in the subsequent years he was made the subject of the bitter attacks of Junius, in which his early Jacobite connexions, and his apparent leanings to arbitrary power, were used against him with extraordinary ability and virulence. In 1776 he was created earl of Mansfield. In 1783, although he declined to re-enter the cabinet, he acted as speaker of the House of Lords during the coalition ministry, and with this his political career may be said to have closed. He continued to act as chief justice until his resignation in June 1788, and after five years spent in quiet retirement died peacefully on 20th March 1793. He left no family, but his title had been re-granted (in 1792) with a direct remainder to his nephew, Lord Stormont.

Lord Mansfield's great reputation rests chiefly on his judicial career. The political trials in which he presided, although they gave rise to numerous accusations against him, were conducted with singular fairness and propriety. He was accused with especial bitterness of favouring arbitrary power by the law which he laid down in the trials for libel which arose out of the publications of Junius and Horne Tooke, and which at a later time he reaffirmed in the case of the dean of St Asaph (see LIBEL). But, although his political opinions led him to look with disfavour on the popular view, and although it was unquestionably unfortunate that in some of these instances he was a member of the cabinet which directed the proceedings, we must remember that his view of the law was concurred in by the great majority of the judges and lawyers of that time, and was supported by undoubted precedents. In other instances, when the Government were equally concerned, he was wholly free from suspicion. He supported Lord Camden's decision against general warrants, and reversed the outlawry of Wilkes. While on the whole he leaned in opinion to a view of the law which we should now call oppressive, there is no instance in which he can justly be accused of wresting it, and in every instance he treated the accused with a fairness and decency which had not always been shown by his predecessors. In another way he came into conflict with popular prejudices. He was always ready to protect the rights of conscience, whether they were claimed by Dissenters or Catholics, and the popular fury which led to the destruction of his house during the Gordon riots was directed against him very much because a Catholic priest, who was accused of saying mass, had escaped the penal laws by his charge to the jury. His chief celebrity, however, is founded upon the consummate ability with which he discharged the civil duties of his office. He has always been recognized as the founder of English mercantile law. The common law as it existed before his time was wholly inadequate to cope with the new cases and customs which arose with the increasing development of commerce. The facts were left to the jury to decide as best they might, and no principle was ever extracted from them which might serve as a guide in subsequent cases. Lord Mansfield found the law in this chaotic state, and left it in a form that was almost equivalent to a code. Working patiently with the guildhall juries, whom he trained to act in thorough understanding with him, he defined almost every principle that governed commercial transactions in such a manner that his successors had only to apply the rules he had laid down. His knowledge of Roman and foreign law, and the general width of his education, freed him from the danger of relying too exclusively upon narrow precedents, and afforded him a storehouse of principles and illustrations, while the grasp and acuteness of his intellect enabled him to put his judgments in a form which almost always commanded assent. A similar influence was exerted by him in other branches of the common law; and although, after his retirement, a reaction took place, and he was recarded for a while as one who had corrupted the ancient principles of English law, these prejudices passed rapidly away, and the value of his work in bringing the older law in harmony

with the needs of modern society has long been fully recognized.

The chief defect of Lord Mansfield's character was a certain coldness and want of moral courage. He had no very warm attachment either to persons or opinions, although invariably kindly and considerate in his demeanour. Even his greatest speeches owe their impressiveness to a certain intellectual nobleness and breadth of view. His attachment to justice was not impassioned, but of the type which is bred from highest professional custom, and from the kind of intellectual taste which led him so frequently to the ethical writings of Cicero. He could not always face the enthusiasm of Chatham, and we cannot feel certain that his courage would have sustained him through any very perilous stand for righteousness. But in the sphere in which he was chiefly famous these defects were scarcely disadvantages. His sense of duty and of personal dignity was amply sufficient to bear him perfectly unstained through life. No suitor had ever to complain of delay or neglect. His want of strong feeling only permitted him to use his magnificent intellect with greater impartiality; and, if at any time he was affected by personal prejudice, no trace of it was ever allowed to appear. Nothing ever disturbed the perfect dignity and propriety of his judicial conduct, which is apparent in every trial at which he presided. He impressed himself on the mind of his contemporaries as one of the best examples of what a great judge ought to be, and from that estimate a closer examination of his claims will scarcely lead us to differ. (A. GI.)

MANSLAUGHTER. See MURDER.

MANSON, GEORGE (1850–1876), a Scottish water-colour painter, was born in Edinburgh on the 3d of December 1850. When about fifteen he was apprenticed as a woodcutter with Messrs W. & R. Chambers, with whom he remained for over five years, designing and engraving vignettes distinguished by singular rightness and directness of technical method, diligently employing all his spare time in the study and practice of art, and producing in his morning and evening hours water-colours of much delicacy and beauty, like the Milking Time and the Cottage Door. In 1871 he left the Messrs Chambers, and devoted himself exclusively to painting. His subjects were derived from humble Scottish life—especially child life, varied occasionally by portraiture, by landscape, and by views of picturesque architecture. In 1873 he visited Normandy, Belgium, and Holland; in the following year he spent several months in Sark; and in 1875 he resided at St Lô, and in Paris, where he mastered the processes of etching. He afterwards produced a series of plates which promised excellence in the art. Meanwhile in his water-colour work he had been adding more of breadth and power to the tenderness and richness of colour which distinguished his early pictures, and he was planning more complex and important subjects. But his health had been gradually failing, and he was ordered to Lympstone in Devonshire, where he died on the 27th of February 1876. Among his chief productions are the High School Wynd; the Companions—a gipsy girl and her donkey; Waiting for the Boats; What is It?—a child examining an antique clock; and his own portrait as a Sark fisherman. Since his death several exhibitions of his works have been held in London and Edinburgh, and a volume of photographs from his water-colours and sketches, with a memoir by J. M. Gray, was published in 1880. For an account of Manson's technical method as a wood engraver see P. G. Hamerton's *Graphic Arts*, p. 311.

MANSUR, MANSOOR, or more properly, with the article, AL-MANṢÚR, "the victorious," a surname (*laḳab*) assumed by not a few Mohammedan princes. Among the personages commonly referred to by this title the following may be noticed.

1. Abú Ja'far ibn Mohammed, second caliph of the house of 'Abbás, who reigned 754–775 A.D. See MOHAMMEDAN EMPIRE.

2. Abú Ṭáhir Isma'íl ibn Al-Ḳáim, third Fatimite caliph of Africa (946–953). Under Al-Ḳáim, his father, the Fatimites, already weakened by their conflict with the Omayyads of Spain, were threatened with utter ruin by a Berber rising under Abú Yezíd, a poor nonconformist (Ibádí) schoolmaster, who appeared as a religious reformer, and gathered round him the Sunnites, who detested the Fatimites. In 944 Abú Yezíd conquered the capital Ḳairawán, and recognized the spiritual headship of the Spanish caliph. While the Spanish caliph and his vassals stripped the Fatimite of his remoter possessions, Abú Yezíd pressed him at home, and during the siege of Súsa Al-Ḳáim died, and was succeeded by Al-Manṣúr. Then the fortunes of war rapidly turned. Abú Yezíd alienated many of his followers by lapsing into habits of arrogant luxury and by treachery towards the Sunnites. At length he lost all he had won, fell into the hands of Al-Manṣúr, and was put to death (947). The caliph built the city of Mansúríyah on the field of the decisive battle and made it his residence; the empire was rapidly restored, and the Spanish vassals driven from Africa. Al-Manṣúr died at Mansúríyah, and was succeeded by Al-Mo'izz, the conqueror of Egypt (see vol. vii. p. 750 *sq.*).

3. Ibn Abí 'Ámir Moḥammed, commonly called Almanzor by European writers, of an ancient but not illustrious Arab family, which had its seat at Torrox near Algeciras, was born 939 A.D., and began life as a lawyer at Cordova. In 967 he obtained a place at the court of Ḥakam II., the Andalusian caliph, and by an unusual combination of the talents of a courtier with administrative ability and address in dealing with men, rapidly rose to distinction, enjoying in particular the powerful support of Ṣubḥ, the favourite of the caliph and mother of his heir Hishám. On the death of Ḥakam (976) the accession of a minor gave fresh scope to the genius of Ibn Abí 'Ámir, who threaded his way with consummate but unscrupulous talent through the intrigues of the court, and in 978 became prime minister. He now aimed at absolute dominion. The weak young caliph, absorbed in exercises of piety, was easily reduced to a cipher, but at first Ibn Abí 'Ámir had to share the power with his father-in-law Ghálib, the best general of Andalusia, and his chief aid, along with the mother of Hishám, in the steps that had raised him to power. At last a rupture took place between the two ministers, and ended in a war, in which Ghálib professed himself the champion of the caliph and called in the aid of the Christians of Leon. But his rival had anticipated the struggle; he had long before found means to add military to administrative reputation, and since he rose to the direction of affairs had remodelled the army so as to make it more formidable and more devoted to his cause. Ghálib fell in battle (981); a victorious campaign chastised the Leonese; and on his return to Cordova the victor assumed the regal surname of Al-Manṣúr billah, and became practically sovereign of Andalusia. The caliph was a mere prisoner of state, holding a nominal dignity, and Al-Manṣúr ultimately assumed the title as well as the prerogatives of king (996). Unscrupulous in the means by which he rose to power, he wielded the sovereignty nobly. His strict justice and the enlightened excellence of his internal administration were not less notable than his military prowess. But it is by the latter that he is best known. His arms were the terror of the Christians, and raised the Moslem power in Spain to a pitch it had never before attained. He fought more than

fifty campaigns, all glorious, and destroyed many cities, including the three capitals of Leon, Pampeluna, and Barcelona, and the sacred shrine of Santiago de Compostella. In Africa his armies were for a time hard pressed by the revolt of Zírí, viceroy of Mauretania, but before his death this enemy had also fallen. Al-Mansúr died at Medinaceli 10th August 1002, and was succeeded by his son Modaffar.[1]

4. Abú Yúsuf Ya'kúb ibn Yusuf (Jacob Almanzor), of the Moorish dynasty of the Almohades, the conqueror of Alphonso III. in the great battle of Alarcos (1195), reigned 1184-99.

MANTEGNA, Andrea (1431–1506), one of the chief heroes in the advance of painting in Italy, was born in or near Padua, of very humble parentage. It is said that in his earliest boyhood Andrea was, like Giotto, put to shepherding or cattle-herding; but this can have lasted only a very short while, as his natural genius for art developed with singular precocity, and excited the attention of Francesco Squarcione, who entered him in the guild of painters before he had completed his eleventh year.

Squarcione, whose original vocation was tailoring, appears to have had a remarkable enthusiasm for ancient art, and a proportionate faculty for acting, with profit to himself and others, as a sort of artistic middleman; his own performances as a painter were merely mediocre. He travelled in Italy, and perhaps in Greece also, collecting antique statues, reliefs, vases, &c., forming the largest collection then extant of such works, making drawings from them himself, and throwing open his stores for others to study from, and then undertaking works on commission for which his pupils no less than himself were made available. As many as one hundred and thirty-seven painters and pictorial students passed through his school, established towards 1440, which became famous all over Italy. Mantegna was, as he deserved to be, Squarcione's favourite pupil. Squarcione adopted him as his son, and purposed making him the heir of his fortune. Andrea was only seventeen when he painted, in the church of St Sophia in Padua, a Madonna picture of exceptional and recognized excellence. He was no doubt fully aware of having achieved no common feat, as he marked the work with his name and the date, and the years of his age. This painting was destroyed in the 17th century.

The affectionate relation between Squarcione and Mantegna was not destined to continue long. As the youth progressed in his studies, he came under the influence of Jacopo Bellini, a painter considerably superior to Squarcione, father of the celebrated painters Giovanni and Gentile, and of a daughter Niccolosia; and at some date, which may have been towards 1450, Jacopo gave Niccolosia to Andrea in marriage. This connexion of Andrea with the pictorial rival of Squarcione is generally assigned as the reason why the latter became alienated from the son of his adoption, and always afterwards hostile to him. Another suggestion, which rests, however, merely on its own internal probability, is that Squarcione had at the outset used his pupil Andrea as the unavowed executant of certain commissions, but that after a while Andrea began painting on his own account, thus injuring the professional interests of his chief, and incurring his animosity. The remarkably definite and original style formed by Mantegna may be traced out as founded on the study of the antique in Squarcione's atelier, followed by a diligent application of principles of work exemplified by Paolo Uccello and Donatello, with the practical guidance and example of Jacopo Bellini in the sequel.

Among the other early works of Mantegna are the fresco of two saints over the entrance-porch of the church of S. Antonio in Padua, 1452, and an altarpiece of St Luke and other saints for the church of St Justina, now in the Brera Gallery in Milan, 1453. It is probable, however, that before this time some of the pupils of Squarcione, including Mantegna, had already begun that series of frescos in the chapel of St Christopher, in the church of S. Agostino degli Eremitani, by which the great painter's reputation was fully confirmed, and which remain to this day conspicuous among his finest achievements.[2] The now censorious Squarcione found much to carp at in the earlier works of this series, illustrating the life of St James; he said the figures were like men of stone, and had better have been coloured stone-colour at once. Andrea, conscious as he was of his great faculty and mastery, and of the transcendent display he had here made of these, seems nevertheless to have felt that there was something in his old preceptor's strictures; and the later subjects, from the legend of St Christopher, combine with his other excellences more of natural character and vivacity. Trained as he had been in the study of marbles and the severity of the antique, and openly avowing that he considered the antique superior to nature as being more eclectic in form, he now and always affected precision of outline, dignity of idea and of figure, and he thus tended towards rigidity, and to an austere wholeness rather than gracious sensitiveness of expression. His draperies are tight and closely folded, being studied (as it is said) from models draped in paper and woven fabrics gummed. Figures slim, muscular, and bony, action impetuous but of arrested energy, tawny landscape, gritty with littering pebbles, mark the athletic hauteur of his style. He never changed, though he developed and perfected, the manner which he had adopted in Padua; his colouring, at first rather neutral and undecided, strengthened and matured. There is throughout his works more balancing of colour than fineness of tone. One of his great aims was optical illusion, which he carried out by a mastery of perspective that, though not always impeccably correct, nor absolutely superior in principle to the highest contemporary point of attainment, was worked out by himself with strenuous labour, and an effect of actuality astonishing in those times.

Successful and admired though he was in Padua, Mantegna left his native city at an early age, and never afterwards resettled there; the hostility of Squarcione has been assigned as the cause. The rest of his life was passed in Verona, Mantua, and Rome—chiefly Mantua; Venice and Florence have also been named, but without confirmation.

It may have been in 1450 that he went to Verona; and he painted, though not on the spot, a grand altarpiece for the church of S. Zenon, a Madonna and angels, with four saints on each side. The Marquis Lodovico Gonzaga of Mantua had for some time been pressing Mantegna to enter his service; and the following year, 1460, was perhaps the one in which he actually established himself at the Mantuan court, residing at first from time to time at Goito, but, from December 1466 onwards, with his family in Mantua itself. His engagement was for a salary of 75 lire (about £30) a month, a sum so large for that period as to mark conspicuously the high regard in which his art was held. He was in fact the first painter of any eminence

[1] His life is brilliantly described in vol. iii. of Dozy, *Histoire des Musulmans d'Espagne*.

[2] His fellow-workers were Bono of Ferrara, Ansuino of Forlì, and Niccolò Pizzolo, to whom considerable sections of the fresco-paintings are to be assigned. The acts of St James and St Christopher are the leading subjects of the series. St James Exorcising may have been commenced by Pizzolo, and completed by Mantegna. The Calling of St James to the Apostleship appears to be Mantegna's design, partially carried out by Pizzolo; the subjects of St James baptizing, his appearing before the judge, and going to execution, and most of the legend of St Christopher, are entirely by Mantegna.

ever domiciled in Mantua. He built a stately house in the city, and adorned it with a multitude of paintings. The house remains, but the pictures have perished. Some of his early Mantuan works are in that apartment of the Castello which is termed the Camera degli Sposi,—full compositions in fresco, including various portraits of the Gonzaga family, and some figures of genii, &c. In 1488 he went to Rome at the request of Pope Innocent VIII., to paint the frescos in the chapel of the Belvedere in the Vatican; the duke of Mantua created him a cavaliere before his departure. This series of frescos, including a noted Baptism of Christ, was ruthlessly destroyed by Pius VI. in laying out the Museo Pio-Clementino. The pope treated Mantegna with less liberality than he had been used to at the Mantuan court; but on the whole their connexion, which ceased in 1490, was not unsatisfactory to either party. Mantegna then returned to Mantua, and went on with a series of works—the nine tempera-pictures, each of them 9 feet square, of the Triumph of Cæsar—which he had probably begun before his leaving for Rome, and which are now in Hampton Court. These superbly invented and designed compositions, gorgeous with all splendour of subject-matter and accessory, and with the classical learning and enthusiasm of one of the master-spirits of the age, have always been accounted of the first rank among Mantegna's works. They were sold in 1628 along with the bulk of the Mantuan art treasures, and were not, as is commonly said, plundered in the sack of Mantua in 1630. They are now greatly damaged by patchy repaintings. Another work of Mantegna's later years was the so-called Madonna della Vittoria, now in the Louvre. It was painted in tempera about 1495, in commemoration of the battle of Fornovo, which Gonzaga found it convenient to represent to his lieges as an Italian victory, though in fact it had been a French victory; the church which originally housed the picture was built from Mantegna's own design. The Madonna is here depicted with various saints, the archangel Michael and St Maurice holding her mantle, which is extended over the kneeling Francesco Gonzaga, amid a profusion of rich festooning and other accessory. Though not in all respects of his highest order of execution, this counts among the most obviously beautiful and attractive of Mantegna's works,—from which it must be said that the qualities of beauty and attraction are often excluded, in the stringent pursuit of those other excellences more germane to his severe genius, tense energy passing into haggard passion.

Vasari eulogizes Mantegna for his courteous, distinguished, and praiseworthy deportment, although there are indications of his having been not a little litigious in disposition. With his fellow-pupils at Padua he had been affectionate; and for two of them, Dario da Trevigi and Marco Zoppo, he retained a steady friendship. That he had a high opinion of himself was natural, for no artist of his epoch could produce more manifest vouchers of high and progressive attainment. He became very expensive in his habits, fell at times into difficulties, and had to urge his valid claims upon the duke's attention. After his return to Mantua from Rome his prosperity was at its height, until the death of his wife. He then formed some other connexion, and became at an advanced age the father of a natural son, Giovanni Andrea; and at the last, although he continued launching out into various expenses and schemes, he had serious tribulations, such as the banishment from Mantua of his son Francesco, who had incurred the duke's displeasure. Perhaps the aged master and connoisseur regarded as barely less trying the hard necessity of parting with a beloved antique bust of Faustina. Very soon after this transaction he died in Mantua, on 13th September 1506. In 1517 a handsome monument was set up to him by his sons in the church of S. Andrea, where he had painted the altarpiece of the mortuary chapel.

We have spoken as yet of Mantegna as a painter and architect; he was no less eminent as an engraver, and is reported to have been a sculptor and poet as well, though we are not aware that any verses of his are extant, or that his sculptural practice extended beyond making a drawing for a statue of Virgil. As an engraver his history is somewhat obscure, partly because he never signed or dated any of his plates, unless in one single disputed instance, 1472. The account which has come down to us is that Mantegna began engraving in Rome, prompted by the engravings produced by Baccio Baldini of Florence after Sandro Botticelli; nor is there anything positive to invalidate this account, except the consideration that it would consign all the numerous and elaborate engravings made by Mantegna to the last sixteen or seventeen years of his life, which seems a scanty space for them. To get over this difficulty, it has been suggested, but without any evidence, that he began engraving while still in Padua, under the tuition of a distinguished goldsmith, Niccolò. He engraved about fifty plates, according to the usual reckoning; some thirty of them are indisputable—often large, full of figures, and highly studied. Among the principal examples are Roman Triumphs (not the same compositions as the Hampton Court pictures), A Bacchanal Festival, Hercules and Antæus, Marine Gods, Judith with the Head of Holophernes, the Deposition from the Cross, the Entombment, the Resurrection, the Man of Sorrows, the Virgin in a Grotto. Mantegna has sometimes been credited with the important invention of engraving with the burin on copper. This claim cannot be sustained on a comparison of dates, but at any rate he introduced the art into upper Italy. Several of his engravings are supposed to be executed on some metal less hard than copper. The technique of himself and his followers is characterized by the strongly marked forms of the design, and by the oblique formal hatchings of the shadows. The prints are frequently to be found in two states, or editions. In the first state, the prints have been taken off with the roller, or even by hand-pressing, and they are weak in tint; in the second state, the printing press has been used, and the ink is stronger.

The influence of Mantegna on the style and tendency of his age was very marked, and extended not only to his own flourishing Mantuan school, but over Italian art generally. His vigorous perspectives and trenchant foreshortenings pioneered the way to other artists: in solid antique taste, and the power of reviving the aspect of a remote age with some approach to system and consistency, he distanced all contemporary competition. He did not, however, leave behind him many scholars of superior faculty. His two legitimate sons were painters of only ordinary ability. His favourite pupil was known as Carlo del Mantegna; Caroto of Verona was another pupil, Bonsignori an imitator. Giovanni Bellini, in his earlier works, obviously followed the lead of his brother-in-law Andrea.

The works painted by Mantegna, apart from his frescos, are not numerous; thirty-three or thereabouts are regarded as fully authenticated. We may name, besides those already specified—in the Naples museum, St Euphemia, a fine early work; in Casa Melzi, Milan, the Madonna and Child with Chanting Angels, 1461; in the Tribune of the Uffizi, Florence, three pictures remarkable for scrupulous finish; in the Berlin Museum, the Dead Christ with two Angels; in the Louvre, the two celebrated pictures of mythic allegory—Parnassus, and Minerva Triumphing over the Vices; in the London National Gallery, the Virgin and Child enthroned, with the Baptist and the Magdalen, a late example; the monochrome of Vestals, lately bought from Hamilton Palace; the Triumph of Scipio (or Phrygian Mother of the Gods received by the Roman Commonwealth), a tempera in chiaroscuro, painted only a few months before the master's death; in the Brera, Milan, the Dead Christ, with the two Maries weeping, a remarkable *tour de force* in the way of foreshortening, which, though it has a stunted appearance, is in correct technical perspective as seen from all points of view. With all its exceptional merit, this is an eminently ugly picture. It remained in Mantegna's studio unsold at his death, and was disposed of to liquidate debts. (W. M. R.)

MANTELL, Gideon Algernon (1790–1852), born in 1790 at Lewes, Sussex, rose to eminence as a popular exponent of geology, and contributed many original papers to the literature of the science. Educated for the medical profession, he first practised in his native town, afterwards in Brighton, and finally at Clapham, near London. While devoting himself with industry and success to the duties of a medical man, he yet found time to prosecute researches in the palæontology of the Secondary rocks, particularly in Sussex—a region which he has made for ever classical in the history of discovery. While he was still a country

doctor at Lewes his eminence as a geological investigator was fully recognized on the publication of his work on *The Fossils of the South Downs*, 1822. His most remarkable discoveries were made in the Wealden formations, whence he brought to light and described the remarkable Dinosaurian reptiles known as *Iguanodon*, *Hylæosaurus*, *Pelorosaurus*, and *Regnosaurus*. The memoirs in which he sketched the structure of these strange creatures, and pointed out the probable conditions in which they lived, were recognized by the Geological Society as deserving of its highest honour—the Wollaston medal. The Royal Society also awarded him a Royal medal. Besides these and other contributions to the literature of palæontology and geology, he published from time to time various popular works which had a large sale and did much to spread a knowledge of and interest in the science.[1] Towards the end of his life Dr Mantell retired to London. Though for many years suffering from a severe spinal disease, the result of an accident, he continued with unabated enthusiasm the prosecution of his favourite scientific pursuits, sparing neither pains nor expense towards the attainment of his objects, and kindling in others a spirit of eager desire to further the cause of science. He wrote with great clearness and attractiveness, so that his general works were deservedly popular. As a lecturer also he was almost unrivalled for fluency and eloquence. His name appeared on the list of membership of many learned societies both at home and abroad. He died in 1852

MANTINEIA was one of the most famous cities of Arcadia. It was situated in the long narrow valley, running north and south, which is now called after the chief town Tripolitza. Tegea was in the same valley, about 10 miles south of Mantineia, and the two cities continually disputed the supremacy of the valley. In every great war we find them ranged on opposite sides, except when superior force constrained both. In the Peloponnesus the disputes between Argos and Sparta lasted for centuries; and Mantineia was always an ally of the former. In the war between Sparta and Athens, Mantineia was at first forced to be an ally of Sparta, but in 421 it joined Argos in making an alliance with Athens. The city is said by Strabo to have been founded under Argive instigation, by the union of several villages of the valley; there can be no doubt that this was done in order to maintain a party in the valley hostile to Tegea and Sparta. It is impossible here to trace the varying history of the town. It was one of the chief members of the Arcadian league that helped Epaminondas to break the power of Sparta. It was one of the original members of the Achæan league, but deserted it for the Ætolian. The Achæans and Antigonus Doson captured the city in 222 B.C., and changed its name to Antigoneia, but the emperor Hadrian restored the ancient name. The worship and mysteries of Cora at Mantineia were famous. The valley in which the city lies has no opening to the coast, and the water finds its way, often only with much care and artificial aid, through underground passages (*catabothra*) to the sea. It is bounded on the west by Mount Mænalus, on the east by Mount Artemision. The river Ophis flowed through the city. The position of the town in the centre of this valley route made it of great military importance, and five important battles were fought beside it: in 418 B.C. Sparta defeated the alliance above mentioned; in 362 Epaminondas defeated the Spartans and lost his own life; in 295 Demetrius Poliorcetes defeated the Spartans; in 242 Aratus defeated the Spartans; in 207 Philopœmen defeated the Spartans. In the beginning of the 4th century B.C. Mantineia had 3000 citizens capable of bearing arms.

MANTIS. Probably no other insect has been the subject of so many and widespread legends and superstitions as the common "praying mantis," *Mantis religiosa*, L. (see INSECTS, *Orthoptera*, fam. *Mantidæ*, vol. xiii. p. 152). The ancient Greeks endowed it with supernatural powers (*μάντις*, "a diviner"); the Turks and Arabs hold that it prays constantly with its face turned towards Mecca; the Provençals call it *Prega-Diou* (*Prie-Dieu*); and numerous more or less similar names—preacher, saint, nun, mendicant, soothsayer, &c.,—are widely diffused throughout southern Europe. Children ask it to show them the way, and Mouffet assures us that it rarely or never deceives them; and it is even recorded that one specimen, which alighted on the hand of St Francis Xavier, and which he commanded to sing the praise of God, loudly intoned a very beautiful canticle. In Nubia it is held in great esteem, and the Hottentots, if not indeed worshipping the local species (*M. fausta*), as one traveller has alleged, at least appear to regard its alighting upon any person both as a token of saintliness and an omen of good fortune.

Praying Mantis (*Mantis religiosa*).

Yet these are "not the saints, but the tigers, of the insect world." The front pair of limbs are very peculiarly modified,—the coxa being greatly elongated, while the strong third joint or femur bears on its curved underside a channel armed on each edge by strong movable spines. Into this groove the stout tibia is capable of closing like the blade of a penknife, its sharp, serrated edge being adapted to cut and hold. The arrangement is essentially similar to the sub-chela of *Squilla* and Amphipods among CRUSTACEA (*q.v.*), as well as to the cheliceræ of spiders (see ARACHNIDA). Thus armed, with head raised upon the much-elongated and semi-erect prothorax, and with the half-opened fore limbs held outwards in the characteristic devotional attitude, it rests motionless upon the four posterior limbs waiting for prey, or occasionally stalks it with slow and silent movements, finally seizing it with its knife-blades and devouring it. Although apparently not daring to attack ants, these insects destroy great numbers of flies, grasshoppers, and caterpillars, and the larger South-American species even attack small frogs, lizards, and birds. They are very pugnacious, fencing with their sword-like limbs "like hussars with sabres," the larger frequently devouring the smaller, and the females the males. The Chinese keep them in bamboo cages, and match them like fighting cocks.

The elytra of the common mantis have been compared to a withering willow leaf, a circumstance which not improbably aids in concealing them from their prey. Some of the tropical forms exhibit as perfect mimicry of the leaves as the leaf insects proper (*Phasmidæ*). Bates found a mantis on the Amazon which exactly resembled the

[1] Of these the following may be enumerated—*The Wonders of Geology*, 2 vols.; *The Medals of Creation*, 2 vols.; *Thoughts on a Pebble, or First Lessons in Geology*; *A Geological Excursion round the Isle of Wight*; *Pictorial Atlas of Fossil Remains*; *Thoughts on Animalcules, or a Glimpse at the Invisible World as revealed by the Microscope*; *Petrifactions and their Teachings*.

white ants it preyed upon, while Wallace mentions a Javanese species which mimics a pink orchid flower, and "is said to feed largely on butterflies,—so that it is really a living trap, and forms its own bait!"

The common species fixes its somewnat nut-like egg capsules on the stems of plants in September. The young are hatched in early summer, and resemble the adults, but are without wings.

See Westwood's *Introd. Mod. Class. of Insects*, 1840, and forthcoming monograph of the family.

MANTUA (Italian, *Mantova*), a fortified city of Italy, the chief town of a province, the see of a bishop, and the centre of a military district, lies 95 miles east-south-east of Milan, and 25 miles by rail south of Verona on the way to Modena, occupying, at the height of 88 feet above the level of the Adriatic, an almost insular site in the midst of the swampy lagoons of the Mincio, with their vast reaches of reeds and bulrushes. As the belt of marshy ground along the south side can be laid under water at pleasure, the site of the city proper, exclusive of the considerable suburbs of Borgo di Fortezza to the north and Borgo di San Giorgio to the east, may still be said to consist, as it formerly did more distinctly, of two islands separated by a narrow channel and united by a number of bridges. On the west side lies Lago Superiore, on the east side Lago Inferiore —the boundary between the two being marked by the *Argine del Mulino*, a long covered wooden bridge stretching northward from the north-west angle of the city. As approached from the north by the old road, Mantua presents a beautiful prospect with its "towers and walls and waters." On the highest ground in the city rises the cathedral, built after his death according to the plans of Giulio Romano on the site of the ancient church of Sts Peter and Paul; it has double aisles, a dome-covered transept, and a large tower, popularly assigned to the Roman governor Arius. Architecturally much more important is the church of St Andrew, built towards the close of the 15th century, after plans by Leon Battista Alberti, and consisting of a single barrel-vaulted nave 350 feet long by 62 feet wide. It has a noble façade, with a deeply recessed portico, and a brick campanile of earlier date than the main building. The interior is richly decorated with 18th century frescos. S. Maria delle Grazie, consecrated in 1399 as an act of thanksgiving for the cessation of the plague, has a curious collection of *ex voto* pictures and the tombs of the Gonzaga family. The old ducal palace—one of the largest buildings of its kind in Europe—was commenced in 1302 for Guido Bonaccolsi, and probably completed in 1328 for Ludovico Gonzaga; but many of the accessory apartments are of much later date, and the interior decorations are for the most part the work of Giulio Romano and his pupils. Outside of the city, to the south of Porta Pusterla, stands the Palazzo del Te, Giulio's architectural masterpiece, erected for Frederick Gonzaga; of the numerous fresco-covered chambers which it contains, perhaps the most celebrated is the Sala dei Giganti, where, by a combination of mechanical with artistic devices, the rout of the Titans still contending with artillery of uptorn rocks against the pursuit and thunderbolts of Jove appears to rush downwards on the spectator. Among the educational institutions in Mantua are an academy of arts and sciences (*Accademia Vergiliana*) occupying a fine building erected by Piermarini, a public library founded in 1780 by Maria Theresa, a museum of antiquities dating from 1779, a good botanical garden, and an observatory. The Monte di Pietà was established in 1484, the civil hospital in 1449. Oil, beer, leather, and playing cards are the chief products of the limited local industry. The population increased from 26,687 in 1871 to 28,048 in 1881. As a fortress Mantua was long one of the most formidable in Europe, a force of thirty to forty thousand men finding accommodation within its walls; but it had two serious defects—the marshy climate told heavily on the health of the garrison, and effective sorties were almost impossible.

Mantua was originally an Etruscan town, and had still a strong Etruscan element in its population during the Roman period. It was a Roman municipium; but Martial calls it little Mantua, and, had it not been for Virgil's interest in his native place and in the expulsion of a number of the Mantuans from their lands in favour of Octavian's soldiers, we should probably have heard almost nothing of its existence. In 568 the Lombards found Mantua a walled town of some strength; recovered from their grasp in 590 by the exarch of Ravenna, it was again captured by Agilulf in 601. The 9th century was the period of episcopal supremacy, and in the 11th the city formed part of the vast possessions of Bonifacio, marquis of Canossa. From him it passed to Geoffrey, duke of Lorraine, and afterwards to the Countess Matilda, whose support of the pope led to the conquest of Mantua by the emperor Henry IV. in 1090. Reduced to obedience by Matilda in 1113, the city obtained its liberty on her death, and instituted a communal government of its own, *salva imperiali justitia*. It afterwards joined the Lombard League; and the unsuccessful attack made by Frederick II. in 1236 brought it a confirmation of its privileges. But after a period of internal discord Ludovico Gonzaga attained to power (1328), and was recognized as imperial vicar (1329); and from that time till the death of Ferdinando Carbo in 1708 the Gonzagas were masters of Mantua (see GONZAGA, vol. x. p. 772). Under Gian Francesco II., Ludovico, and Federico II., the first duke of Mantua, the city rose rapidly into importance as a seat of industry and culture. Claimed in 1708 as a fief of the empire by Joseph I., it was governed for the greater part of the century by the Austrians. In June 1796 it was besieged by Napoleon; but in spite of terrific bombardments it held out till February 1797. A three days' bombardment in 1799 again placed Mantua in the hands of the Austrians; and, though restored to the French by the peace of Lunéville (1801), it became Austrian once more from 1814 till 1866. In the years between 1849 and 1859 the city was the scene of violent political persecution.

Besides Virgil, Mantua counts among its celebrities Sordello the Provençal poet, Castiglioni, Folengo the writer of macaronics, and Pomponazzi the philosopher; and it has a long roll of local historians—Donesmondi (ecclesiastical affairs), Possevino, Daino, Amedei, Visi, Tonelli, and Count Carlo d'Arco.

Gaet. Susani, *Nuovo prospetto delle pitture, &c., di Mantova*, Mantua, 1830; Carlo d'Arco, *Delle arti e degli artefici di Mantova*, Mantua, 1857, and *Storia di Mantova*, Mantua, 1874.

MANUCODE, from the French, an abbreviation of *Manucodiata*, and the Latinized form of the Malay *Manuk-dewata*, meaning, says Crawfurd (*Malay and Engl. Dictionary*, p. 97), the "bird of the gods," and a name applied for more than two hundred years apparently to Birds-of-paradise in general. In the original sense of its inventor, Montbeillard (*Hist. Nat. Oiseaux*, iii. p. 163), *Manucode* was restricted to the King Bird-of-paradise and three allied species; but in English it has curiously been transferred[1] to a small group of species whose relationship to the *Paradiseidæ* has been frequently doubted, and must be considered uncertain. These Manucodes have a glossy steel-blue plumage of much beauty, but are easily distinguished from other birds of similar coloration by the outer and middle toes being united for some distance, and they are very remarkable for the extraordinary convolution of the trachea, in the males at least, with which singular structure is correlated the loud and clear voice of the birds. The convoluted portion of the trachea lies on the breast, between the skin and the muscles, much as is found in the females of the genus *Rhynchæa*, in the males of the Curassows (*Cracidæ*), and in a few other birds, but wholly unknown elsewhere among the *Passeres*. The Manucodes are peculiar to the Papuan Sub-region (including therein

[1] *Manucodiata* was used by Brisson (*Ornithologie*, ii. p. 130) as a generic term equivalent to the Linnæan *Paradisea*. In 1783 Boddaert, when assigning scientific names to the birds figured by Daubenton, called the subject of one of them (*Pl. enlum.* 634) *Manucodia chalybea*, the first word being apparently an accidental curtailment of the name of Brisson's genus to which he referred it. Nevertheless some writers have taken it as evidence of an intention to found a new genus by that name, and hence the importation of *Manucodia* into scientific nomenclature, and the English form to correspond.

the peninsula of Cape York), and comprehend, according to Mr Sharpe (*Cat. B. Brit. Museum*, iii. p. 164), two genera, for the first of which, distinguished by the elongated tufts on the head, he adopts Lesson's name *Phonygama*, and for the second, having no tufts, but the feathers of the head crisped, that of *Manucodia*; and Mr W. A. Forbes (*Proc. Zool. Society*, 1882, p. 349) observes that the validity of the separation (which has not yet been generally acknowledged) is confirmed by what is now known of their tracheal formation. Of *Phonygama* Mr Sharpe recognizes three species, *P. keraudreni* (the type) and *P. jamesi*, both from New Guinea, and *P. gouldi*, the Australian representative species; but the first two are considered by Mr Elliot (*Ibis*, 1878, p. 56) and Count Salvadori (*Ornitol. della Papuasia*, ii. p. 510) to be inseparable. There is a greater unanimity in regard to the species of the so-called genus *Manucodia* proper, of which four are admitted — *M. chalybeata* or *chalybea* from north-western New Guinea, *M. comriei* from the south-eastern part of the same country, *M. atra* of wide distribution within the Papuan area, and *M. jobiensis* peculiar to the island which gives it a name. Little is known of the habits of these birds, except that they are as already mentioned remarkable for their vocal powers, which, in *P. keraudreni*, Lesson describes (*Voy. de la Coquille*, Zoologie, i. p. 638) as enabling them to pass through every note of the gamut. Mr Wallace (*Ann. Nat. History*, ser. 2, xx. p. 476) remarked that *M. atra* was very powerful and active, clinging suspended to the smaller branches of trees, on the fruits of which alone it appears to feed. *M. gouldi*, according to an informant quoted by Mr Forbes (*ut supra*), frequents in pairs the dense palm-forests, perching high up, uttering a very deep and loud guttural note; it is graceful in its movements, evincing more curiosity than timidity on being approached. As with members of the *Paradiseidæ* generally, the nidification of the Manucodes is still shrouded in mystery. (A. N.)

MANUEL I., Comnenus, emperor of Constantinople from 1143 to 1184, was the fourth son of John II. (Calo-Joannes), and was born about the year 1120. He succeeded to the imperial crown on April 8, 1143, having for his martial qualities been nominated by John to the inheritance in preference to his elder surviving brother. During his reign of thirty-seven years he was involved in almost perpetual war, in which he displayed much more of the courage of a soldier than of the prudence and skill of a commander. In 1144 the imperial general Demetrius Branas brought back Raymond, the Latin prince of Antioch, to his allegiance, and in 1145 Manuel in person drove out the Turks who had invaded Isauria, and compelled them to accept peace on his own terms. In 1147 he granted a passage through his dominions to the crusaders under Louis VII. of France and Conrad III. of Germany, but secretly harassed them by every means in his power, and sent word to the Turks of their approach. In the following year he became involved, along with the Venetians, in a war with Roger of Sicily, who had taken Corfu and invaded Greece; an episode of the campaign towards its beginning was his repulse beyond the Danube of the Patzenegues, of whom he took hostages for their future good behaviour. Disembarking his host at Corfu before the end of the year, he invested the fortress in co-operation with the Venetian army; the inhabitants, after a long siege, in which he displayed prodigies of personal strength and valour, surrendered in 1149. Manuel was now prevented from invading Sicily by a diversion made by the Servians and Hungarians on the Danube, who were not completely vanquished until 1152. In that year Manuel was repulsed by the Turks in Cilicia, but in the west his troops obtained possession of Bari, Brundisium, and other places of importance in Apulia and Calabria. The course of Italian politics, however, deprived him of the means on which he had reckoned for enabling him to reunite southern Italy with the Byzantine empire, and after the defeat of his fleet at Negropont he concluded a peace with William, Roger's successor, in 1155. The next important war of Manuel's reign was waged against the Hungarians from 1163 to 1168; it came to an end in the latter year with the hard-won victory of the Byzantine arms at Zeugminum (Semlin). Less successful was the expedition under Andronicus Contostephanus against Egypt in 1169, when the combined forces of Manuel and King Amalric were compelled to withdraw from before Damietta. From 1171 to 1174 Manuel had a war with the Venetians; and in 1176 he led in person an expedition against Kilidj Arslan, the sultan of Iconium when he sustained a disastrous defeat at Myriocephalus, and was compelled to sign a dishonourable peace. This disgrace, although partially retrieved by a somewhat more successful expedition in 1177, so preyed upon the spirit of Manuel that he ultimately succumbed to a slow fever on September 24, 1180. He was first married to Bertha (Irene), a relative of Conrad III. of Germany, and afterwards to Maria (Xene), daughter of Raymond of Antioch; Alexis II., his son by the latter, succeeded him.

MANUEL II., Palæologus, emperor of Constantinople, was born in 1348, and succeeded his father, John VI. (with whom he had been associated since 1375), in 1391. At the time he was a hostage at the court of Bajazet at Nicæa, but succeeded in making his escape; he was forthwith besieged in Constantinople by the sultan, whose victory over the Christians at Nicopolis, however (September 28, 1395), did not secure for him the capital. Manuel subsequently set out in person to seek help from the West, and for this purpose visited Italy, France, and Germany, but without material success; the victory of Timur in 1402, and the death of Bajazet in the following year, were the first events to give him a genuine respite from Ottoman oppression. He stood on friendly terms with Mahomet I., but was again besieged in his capital by Amurath II. in 1422. He died in 1425, and was succeeded by his son, John VII.

MANUEL I., emperor of Trebizond, surnamed the Great Captain (ὁ στρατηγικώτατος), was the second son of Alexius I., first emperor of Trebizond, and ruled from 1238 to 1263. Whatever may have been his military skill, or his personal character for bravery, he was unable to deliver his empire from vassalage first to the Seljuks and afterwards to the Mongols. He was the founder of the church and monastery of St Sophia at Trebizond. His predecessor was John I., Axuchus, and his eldest son, Andronicus II., succeeded him.

Manuel II., the descendant of Manuel I., reigned only a few months in 1322–23. Manuel III. reigned from 1390 to 1417, but the only interest attaching to his name arises from his connexion with Timur, whose vassal he was.

See Finlay, *Mediæval Greece and Trebizond*, 1851.

MANURE. The term "manure," though formerly applied only to the excrements of animals, either alone or mixed with straw, is now more widely used, and is given to all substances, or mixtures of substances, which are added to the soil in order to increase its productiveness or to restore the natural fertility lost by repeated cropping.

The subject of manures and their application involves a prior consideration of plant life and its requirements. The plant, growing as it does in the soil, and surrounded by the atmosphere, derives from these two sources its nourishment and means of growth through the various stages of its development. From these sources, each equally indispensable, the plant obtains the materials which it has the power of elaborating and building up to form its own structure.

Chemical analysis has shown that plants are composed

of water, organic or combustible matters, and inorganic, incombustible, or mineral matters. These last are left as the ash when the plant is burnt. The elements forming the organic portion of plants are carbon, hydrogen, oxygen, and nitrogen; the mineral portion, or ash, consists principally of lime, magnesia, potash, soda, oxide of iron, phosphoric acid, sulphuric acid, chlorine, and silica.

The atmosphere is the great storehouse of organic plant-food. The carbonic acid always present in the air is, as is well known, eagerly taken up by the leaves of plants, all of which have the power of decomposing carbonic acid, giving off its oxygen, and assimilating its carbon. Roughly speaking, three-fourths of the dry substance of all plants is derived from the atmosphere.

Under conditions of natural growth and decay, when no crops are gathered in, or consumed on the land by live stock, the herbage on dying down and decaying returns to the atmosphere and the soil the elements taken from them during life; but under cultivation a succession of crops deprives the land of the constituents which are essential to healthy and luxuriant growth. Without an adequate return to the land of the matters removed in the produce, its fertility cannot be maintained for many years. In newly-opened countries, where old forests have been cleared and the land brought into cultivation, the virgin soil often possesses at first a high degree of fertility, but gradually its productive power decreases from year to year. Generally speaking, it is more convenient to clear fresh forest land than to improve more or less exhausted virgin land by the application of manure, labour, and skill. In all densely peopled countries where such a mode of cultivation cannot be followed it is necessary to resort to artificial means to restore the natural fertility of the land and maintain and increase its productiveness.

The researches of Liebig, Wiegmann, Polstorff, and others have proved beyond doubt the important functions of the mineral constituents of the soil in relation to plant life. The gradual removal of phosphate of lime in the tillage of dairy districts, or the removal of other mineral matters essential to the healthy growth of farm crops, certainly impoverishes the land. The exhaustion of the soil is caused in a much more marked way, however, by the rapid loss in available nitrogenous plant food which soils sustain when under cultivation without manure.

Agricultural improvements manifest themselves in two different directions—the mechanical and the chemical. Under mechanical improvement the physical condition of the soil is bettered and its latent stores of plant food brought into action by mechanical means, such as ploughing, subsoiling, steam cultivation, &c. The introduction of new and superior agricultural implements, good systems of drainage, and intelligent division of labour characterize the first stage of progress in agriculture. The second stage is marked by the application of chemical principles to practical agriculture, an application shown by the introduction of a rational system of feeding, a proper rotation of crops, and chiefly the use of chemical, or artificial, manures for the purpose of restoring the natural fertility of the soil and increasing its productive powers.

The aid which chemistry has rendered during the last twenty-five or thirty years to practical agriculture has greatly promoted agricultural improvements; and farming, which is in a large measure dependent for success upon an economical use of manures, is now being carried on much more rationally than in former times. The proper application of various kinds of manures is one of the most prominent features of successful modern farming.

In considering the economical use of manures on the land, regard must be had to the following points:—(1) the requirements of the crops intended to be cultivated; (2) the physical condition of the soil; (3) the composition of the soil; and (4) the composition of the manure. Briefly stated, the guiding principle of manuring economically and profitably is to meet the requirements of the crops intended to be cultivated, by incorporating with the soil, in the most efficacious states of combination, the materials in which it is deficient, or which the various crops usually grown on the farm do not find in the land in a sufficiently available condition to ensure an abundant harvest.

Soils vary greatly in composition, and hence it will be readily understood that in one locality or on one particular field a certain manure may be used with great benefit, while in another field the same manure has little or no effect upon the produce. Although increased attention has of recent years been paid to the chemical composition and properties of soils, there is still much room left for improvement, for many farmers disregard almost altogether the composition of their fields in buying artificial manures.

It has been pointed out by Sir John Lawes that in actual English farm-practice there is, speaking practically, a standard of natural produce which varies within certain limits, as influenced by seasons and management, and which cannot be permanently increased or reduced by cultivation; and further, when land is spoken of as being in "good condition," reference is made only to the temporary rise of fertility by means of the manures employed, while by land "out of condition" is signified the exhaustion of the manures by the removal of crops, loss by drainage, &c., and that the soil has merely gone back to its standard of natural productiveness. Some soils, indeed, contain in their natural condition hardly a sufficient proportion of available elements of plant food to yield remunerative crops; such soils are naturally barren, and, although by the constant use of manures they may be improved and may attain some degree of fertility, they will, if left unmanured, speedily revert to their former natural unproductive state.

The principal constituents of manures are—nitrogen, in the form of ammonia, nitrates, and nitrogenous organic matters; organic matters not containing nitrogen (humus); phosphoric acid, potash, soda, lime, magnesia, silica, sulphuric acid, and chlorine. Of these constituents by far the most important are the nitrogen, phosphoric acid, and potash, and these will be considered more in detail.

1. *Nitrogen.*—Nothing so much affects the productiveness of soils as nitrogen, when it is supplied to plants in a form in which it can be assimilated by them, and nothing is more readily removed from the land, either in the crop grown or, in the form of nitrates, by drainage. The "good condition" of land, to which allusion has been made already, is, in a great measure, the fertility which has been imparted to the soil by the nitrogen supplied to it, while the "natural productiveness" may be taken as that due to the phosphoric acid, potash, and other mineral constituents of the soil.

*Supply of Nitrogenous Plant Food.*—In the case of a crop growing under natural conditions, and not removed from the land, the mineral constituents taken from the soil, and carbonaceous as well as some nitrogenous organic matter, principally derived from the atmosphere, are returned to the land, and a rich carbonaceous soil or humus is produced in the course of years. Such a soil is capable of supplying for a considerable number of years, when under cultivation, the nitrogen needed by the crops grown on the land. This supply of nitrogen, however, gradually becomes exhausted by repeated cropping. The atmosphere, in addition to free nitrogen gas, which constitutes about four-fifths of its volume, contains but very little combined nitrogen in the forms of ammonia or nitric acid.

M. Boussingault's experiments clearly show that plants

do not possess the power of taking up by their leaves and of assimilating the free nitrogen of the air. This conclusion has been verified by the extensive researches of Messrs Lawes, Gilbert, and Pugh. The nitrogen contained as nitric acid and ammonia in the air, and descending upon the land in the shape of rain, dew, or snow, though, without doubt, adding to the supply of nitrogen in the soil, is altogether insufficient to meet the requirements of remunerative crops. The experiments of Messrs Lawes and Gilbert and Professor Way show that the average proportion of nitrogen deposited annually upon one acre of land at Rothamsted, St Albans, amounts to 7·21 lb, of which quantity 6·46 lb occur as ammonia and ·75 lb as nitric acid.

The further investigations of Dr Voelcker, Professor Frankland, and Messrs Lawes and Gilbert upon the drainage water from cultivated soils show that a considerable quantity of nitrogen in the shape of nitric acid passes into land drainage, and that this loss of nitrogen is much greater than the total amount supplied to the land by the rain and dew. The results which Messrs Lawes and Gilbert obtained in their experiments on the continuous growth of barley at Rothamsted from 1852 to 1875 afford, as is shown in the following table (I.), direct evidence of the insufficiency of the atmospheric supply of nitrogen, and of that present in the soil in the form of nitrogenous organic matter.

TABLE I.—*Messrs Lawes and Gilbert's Experiments on the Growth of Wheat and Barley, year after year on the same Land, without Manure, and with different kinds of Manure.*

| Manures per Acre per Annum. | Produce per Acre (Average per Annum). | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | Dressed Corn. | | | | | | Total Straw. | | |
| | Quantity. | | | Weight per Bushel. | | | | | |
| | 12 Years 1852–63. | 12 Years 1864–75. | 24 Years 1852–75. | 12 Years 1852–63. | 12 Years 1864–75. | 24 Years 1852–75. | 12 Years 1852–63. | 12 Years 1864–75. | 24 Years 1852–75. |
| *Wheat.*[1] | bush. | bush. | bush. | lb | lb | lb | cwts. | cwts. | cwts. |
| 1. Unmanured continuously | 15½ | 12⅜ | 14 | 56½ | 59 | 57¾ | 14½ | 9¾ | 12⅜ |
| 2. Mineral manures alone (200 lb sulphate of potash, 100 lb sulphate of soda, 100 lb sulphate of magnesia, and 3½ cwts. of superphosphate made from 200 lb bone ash, 150 lb sulphuric acid of 1·7 specific gravity, and water) | 18½ | 13⅜ | 16⅛ | 57⅞ | 59½ | 58⅞ | 16⅞ | 14⅛ | 14⅛ |
| 3. Ammonia salts alone for 1845, and each year since; mineral manure in 1844 (equal parts of sulphate and muriate of ammonia of commerce) | 22⅝ | 21⅛ | 21⅞ | 55⅞ | 58 | 56⅝ | 23½ | 18½ | 20⅞ |
| 4. Ammonia salts and minerals. (The same minerals as in No. 2, and 600 lb ammonia salts.) | 38 | 37 | 37½ | 57⅜ | 60½ | 59 | 42½ | 40½ | 41½ |
| 5. Farmyard manure (14 tons every year) | 35⅜ | 35 | 35⅛ | 59½ | 60⅝ | 60 | 34⅜ | 32⅜ | 33⅜ |
| *Barley.*[2] | | | | | | | | | |
| 1. Unmanured continuously | 21⅞ | 15⅞ | 18⅜ | 51⅛ | 53½ | 52⅛ | 12⅞ | 9½ | 11 |
| 2. Mineral manure alone (200 lb sulphate of potash, 100 lb sulphate of soda, 100 lb sulphate of magnesia, and 3½ cwts. of superphosphates) | 30⅜ | 21½ | 25⅞ | 52½ | 54½ | 53½ | 15⅞ | 10⅞ | 13⅜ |
| 3. Superphosphate alone (3½ cwts.) | 27½ | 20⅜ | 24⅛ | 52½ | 54⅜ | 53½ | 14⅜ | 10½ | 12⅜ |
| 4. Ammonia salts alone (200 lb) | 34½ | 29 | 31⅜ | 51½ | 53½ | 52½ | 19⅞ | 15⅜ | 17½ |
| 5. Nitrate of soda (275 lb) | 30⅝ | 32½ | 36 | 51 | 53⅜ | 52½ | 23⅝ | 18⅜ | 21⅜ |
| 6. Ammonia salts and minerals. (The same minerals as in No. 2, and 200 lb ammonia salts.) | 47⅛ | 44 | 45½ | 52⅜ | 55⅜ | 54½ | 29⅜ | 26½ | 27⅞ |
| 7. Nitrate of soda and minerals. (The same minerals as in No. 2, and 275 lb nitrate of soda.) | 50⅜ | 46⅜ | 48½ | 51⅞ | 55½ | 53⅜ | 34⅜ | 28 | 31½ |
| 8. Farmyard manure (14 tons every year) | 46⅝ | 50½ | 48⅞ | 53½ | 55½ | 54⅜ | 27⅞ | 29⅜ | 28⅞ |

The Rothamsted soil is a moderately stiff one, of considerable depth, and contains naturally the mineral elements of plant food in abundance; thus it has been possible to grow corn crops for over twenty-five years without any manure (Plots 1). The crops in the second period of twelve years were, however, less than those of the first period, and in neither case were full crops obtained. While the application of mineral manures alone (Plots 2) produced only a slight increase in the case of the wheat, and rather better, though poor, results with barley, nitrogenous manures, applied to the land either in the shape of ammonia salts or nitrate of soda, produced a strikingly large increase. The experiments further show that while good crops, both of wheat and barley, can be grown by the annual application of 14 tons of farmyard manure per acre, the best results are obtained by the use of a mixture of mineral and nitrogenous manures.

In Messrs Lawes and Gilbert's experiments the amount of nitrogen removed in different crops was determined with the following results:—over a period of thirty-two years (to 1875), wheat yielded an average of 20·7 lb of nitrogen per acre per annum without any manure, but the annual yield has decreased from an average of over 25 lb in the first eight to less than 16 lb in the last twelve years, and since 1875 it has been still less; over a period of twenty-four years, barley, when unmanured, yielded an average of 18·3 lb nitrogen per acre per annum, but with a decline from 22 lb in the first twelve to 14·6 in the last twelve years. Experiments similar to those on wheat and barley have been made on oats, root crops, leguminous and grass crops, all showing the gradual decline in produce when grown continuously without nitrogenous manures, and proving that the soil and not the atmosphere is the chief source of nitrogen in plants. In face of these results the "mineral theory" of Liebig, which attached but small value to nitrogen applied to the soil in the form of nitrogenous manures, and maintained the sufficiency of the ammonia of the atmosphere for supplying the needs of the plant, cannot be accepted without reserve.

Notwithstanding the great effect produced by the nitrogenous manures, two-thirds of the nitrogen supplied was unrecovered in the increase of crops when the ammonia salts were supplied to wheat in autumn. When, however, nitrate of soda was used, which is always applied in the spring, the quantity left unrecovered was not much more than half that supplied.

The following table (II.), by Messrs Lawes and Gilbert, shows the amount of nitrogen recovered, and the amount not recovered, in the increase of the crop for 100 supplied in manure, to wheat and to barley respectively, the result being in each case the average over a period of twenty years:—

[1] Previous cropping:—1839, turnips with farmyard manure; 1840, barley; 1841, pease; 1842, wheat; 1843, oats; the last four crops unmanured. First experimental wheat crop in 1844. Wheat every year since; and, with some exceptions, nearly the same description of manure on the same plots each year—especially during the last twenty-six years (1852 and since). Unless otherwise stated, the manures are sown in the autumn before the seed. Area under experiment about 13 acres.

[2] Previous cropping:—1847, swedish turnips with dung and superphosphate of lime, the roots carted off; 1848, barley; 1849, clover; 1850, wheat; 1851, barley manured with ammonia salts. First experimental crop in 1852. Barley every year since.

TABLE II.

| Manuring quantities per Acre per Annum. | Wheat. 20 Years 1852–71. Recovered in Increase. | Wheat. 20 Years 1852–71. Not recovered in Increase. | Barley. 20 Years 1852–71. Recovered. | Barley. 20 Years 1852–71. Not recovered. |
|---|---|---|---|---|
| Complex mineral manure and 41 lb of nitrogen as ammonia | 32·4 | 67·6 | 48·1 | 51·9 |
| Complex mineral manure and 53·3 lb of nitrogen as ammonia | ... | ... | 49·8 | 50·2 |
| Complex mineral manure and 82 lb of nitrogen as ammonia | 32·9 | 67·1 | ... | ... |
| Complex mineral manure and 123 lb of nitrogen as ammonia | 31·5 | 68·5 | ... | ... |
| Complex mineral manure and 164 lb of nitrogen as ammonia | 28·5 | 71·5 | ... | ... |
| Complex mineral manure and 82 lb of nitrogen as nitrate | 45·3 | 54·7 | ... | ... |
| Complex mineral and rape cake (61·75 lb of nitrogen) | ... | ... | 36·3 | 63·7 |
| Farmyard manure (about 200 lb of nitrogen) | 14·6 | 85·4 | 10·7 | 89·3 |

The question will naturally be raised, What becomes of the one-half or two-thirds of the nitrogen which is not recovered in the increase of the crops? The examination of some seventy samples by Dr Voelcker, and a number of independent determinations by Dr Frankland, of the drainage-water from the experimental wheat plots which yielded the above results throw much light on this loss. The following table (III.) contains a summary of some of the more important results obtained.

TABLE III.—*Nitrogen as Nitrates and Nitrites, per* 100,000 *parts of Drainage Water from Plots differently Manured, in the Experimental Wheat-field at Rothamsted, Wheat every year, commencing* 1844.

| Mean of Dr Voelcker's and Dr Frankland's Results. | Experiments. | Nitrogen. |
|---|---|---|
| Farmyard manure | 6 | 1·264 |
| Without manure | 11 | 0·353 |
| Complex mineral manure | 11 | 0·428 |
| Do. and 41 lb nitrogen as ammonia | 11 | 0·822 |
| Do. and 82 lb nitrogen as ammonia | 11 | 1·439 |
| Do. and 123 lb nitrogen as ammonia | 11 | 1·815 |
| Do. and 82 lb nitrogen as nitrate | 10 | 1·437 |

These experiments show how great may be the loss of nitrogen by drainage when ammonia salts or nitrates are liberally applied to the land in autumn, should there be much wet weather in winter, or even when applied in spring if there be much heavy rain; also, that the quantity of nitrogen in drainage water as nitrates is increased in proportion to the amounts of ammonia or nitrate employed on the land. Assuming that from one-quarter to nearly one-half the annual rainfall descends more than 40 inches below the surface, every inch of rain passing through the drains and carrying with it one part of nitrogen in 100,000 of water, there will be a loss of 2½ lb of nitrogen per acre from the manure. Dr Voelcker's analysis of the drainage water of a wheat field manured in autumn by ammonia salts supplying 82 lb of nitrogen per acre shows that for every inch of rain passing through the drains in January a loss took place of about 8½ lb of nitrogen, costing about 1s. per lb as manure. The loss of nitrogen thus is very large, and shows that by far the largest proportion of the nitrogen of manure which is not recovered in the crop is lost in drainage. In addition to the nitrogen removed in the crop and to that lost in drainage, some small proportion is found by analysis to be retained in the soil itself. The nitrogen may be of advantage to crops grown subsequently, according to the source from which it was derived; for while ammonia salts and nitrates yield but very small residues, and exert little or no effect beyond the first year, from bones, cake, and other such materials we get large residues of nitrogen in the soil, which tell markedly on future crops. The experiments on drainage water have further shown the absorbent power of soils, and that manuring matters when in contact with soils undergo remarkable changes, being taken up by plants, not in the simple state in which they are applied, but in quite different kinds of combination. Professor Way has the merit of having first proved that all soils possess, in different degrees, the power of absorbing ammonia from its solution in water, and that in passing solutions of salts of ammonia through soils the ammonia alone is absorbed, and the acids of the ammonia salts pass through in combination, generally with lime, or, if lime be deficient, with magnesia or other mineral bases of the soil.

In the drainage investigations at Rothamsted, it was found that, although large quantities of ammonia salts were applied to some of the plots, the drainage water from them contained mere traces of ammonia, but at all times of the year nitrates were present in quantity; from this it would appear that it is chiefly, if not solely, from nitrates that crops build up their nitrogenous organic constituents. Before leaving the subject of drainage water it is worthy of note here that phosphoric acid and potash, the most valuable mineral fertilizing constituents of the manures, passed but little into the drainage water, but were retained almost entirely in the land, while the more abundant and less important mineral matters, such as lime, magnesia, soda, chlorine, sulphuric acid, and soluble silica, passed in large quantities into the drainage water. It follows from these investigations, first, that much more nitrogenous material must be applied to the land than would be needed to produce a given increase in the crop, supposing all the nitrogen to be recoverable; and secondly, that nitrogenous organic matters when applied to the land undergo decomposition, and are gradually resolved into ammonia compounds, which, after being retained a short time by the soil, are finally oxidized into nitrates, in which form they are most available and beneficial to plants, but are not absorbed by the soil, and are readily washed out by rain. Nitrogen has great forcing properties, and is most beneficial when applied to crops in their early stages. Grass land on which nitrate of soda has been put as a top dressing shows very rapidly and markedly the effects of the manure.

Nitrate of soda, unless applied just at the time the crop is ready to take it up, will be largely wasted in drainage; hence it is usual to apply nitrate of soda as a top dressing in spring. Ammoniacal manures, such as Peruvian guano, soot, sulphate of ammonia, &c., when used for winter wheat, are best applied in autumn, either before the wheat is sown or when it is fairly above ground. On light land they are often used as top dressings for wheat early in spring. The gradual decomposition of farmyard manures gives a more constant supply of nitrogen than the manures already noticed, and as the fermentation of dung proceeds but slowly it is best to apply it, when quite fresh, in autumn or winter, allowing it to decompose in the land and to yield nitrogen as nitrates when required in spring by the fresh growth of vegetation. In the case of nitrogenous organic materials, such as wool or hair refuse, which take even longer than farmyard manure to decompose, it is necessary to apply them some three or four months before the seed is sown.

2. *Phosphoric Acid.*—Next in value to nitrogen as a constituent of manures comes phosphoric acid. Of all the mineral or ash constituents of plants, this is the most important, for the simple reason that it occurs in most soils in comparatively small proportions, and is required alike by corn and forage crops in larger quantities than lime, magnesia, and other mineral matters, which occur in most soils in almost inexhaustible quantities, or which, if deficient, can be easily and cheaply incorporated with the land.

Phosphoric acid occurs in soils principally in combination with lime as phosphate of lime, a constituent which enters

largely into the composition of recent and fossil bones, coprolites, and guano, and of a variety of phosphatic minerals, such as Norwegian and Canadian apatite, Sombrero and Curaçoa rock phosphate, South Carolina phosphate, Spanish and Portuguese phosphorite, &c. These and other phosphatic materials are now used largely in the manufacture of superphosphate and other artificial manures.

Phosphate of lime is so sparingly soluble in pure water that, for all practical purposes, it may be considered to be insoluble in water; it is, however, attacked by the natural agencies at work in the soil, and rendered available as plant food. According to the more or less porous condition of the phosphatic manuring materials, phosphate of lime is rendered more or less readily assimilable. Thus, while bone dust and guano, on account of their porous condition, may be used with good effect as suppliers of phosphoric acid to the soil, others, such as hard and crystalline Canadian or Norwegian apatite, produce but little or no result when used as manures merely in a powdered state. It was in 1840 that Liebig suggested the treatment of bones with sulphuric acid in order to make their action more rapid. This treatment of bones by acid converts the phosphate of lime into a soluble lime salt called superphosphate, or, speaking chemically, transforms the original tribasic phosphate of lime into the monocalcic phosphate, sulphate of lime being at the same time produced. Following on this, Mr (now Sir) John Lawes treated mineral phosphates similarly with sulphuric acid, and with results which led to the establishment of a new industry, the manufacture of superphosphate and other artificial manures. The yearly importation of phosphatic minerals, &c., into England for this manufacture alone exceeds 500,000 tons.

The acid or soluble phosphate of lime in superphosphate, when applied to the soil, is first dissolved by the rain, and equally distributed in a portion of the soil, in which it must be precipitated and rendered insoluble before it can be assimilated by the plant. It is this intimate distribution and subsequent precipitation in a most finely divided state that would seem to constitute the beneficial effects of superphosphate, and its superiority over undissolved phosphates. It supplies at once phosphoric acid, lime, and sulphuric acid to the soil, and is much used in conjunction with nitrogenous materials. Superphosphates are manufactured of various strengths, the percentage of tribasic phosphate of lime, rendered soluble by acid, being taken as the basis of valuation.

3. *Potash.*—The next to rank after phosphoric acid as a valuable constituent of manures is potash. It enters largely into the composition of all crops, especially root crops. Sandy soils, as a rule, are poor in potash, for which reason they are benefited to a greater extent by the application of potash salts than most clay soils, which contain sufficient potash to meet the requirements of farm crops. In clay soils potash mainly occurs in the form of insoluble silicate of potash together with other silicates. By autumn cultivation, subsoiling, and similar means of facilitating the free access of the air to clay-land potash is gradually liberated from the insoluble silicates and is rendered available as plant food. Lime also seems to be an important agent in the liberation of potash. Potash also occurs in farmyard manure, urine, all excrements in oil cakes, and largely in wood ashes.

Most potash salts are very soluble in water; this explains their greater abundance in the liquid than the solid excrements of animals. On this account it is a matter of importance, in making farmyard manure, to preserve the urine, and not lose the benefit of the potash salts it contains. On most soils in a good agricultural condition the addition of potash manures produces little or no effect, but on poor sandy soils or worn-out pasture land the use of potash salts, in conjunction with superphosphate, dissolved bones, and guano, is followed by most beneficial results. Potash salts as an addition to manures for potatoes have been found advantageous, while their effect on pasture seems to be to improve the quality of the herbage rather than to increase the yield of grass per acre.

4. *Soda.*—Most soils contain in abundance all the soda that farm crops require. With the exception of chloride of sodium (common salt), which occasionally is applied with more or less benefit to light sandy soils, and of nitrate of soda, which is employed as a nitrogenous manure, soda salts are not used for manuring purposes.

5. *Lime.*—Lime is essential for the production of healthy crops. Experience has shown that, when a soil is deficient in lime, farmyard manure, Peruvian guano, and other manures, though used in abundance, produce comparatively but little effect. Again, on poor sandy soils, lime, marl, or chalk not unfrequently produces better crops than farmyard or expensive artificial manures. Lime not only supplies an essential constituent of plants, but also prevents the loss by drainage of fertilizing matters such as potash, ammonia, and phosphoric acid. One of the functions of lime in the soil is to combine with the acids of the potash and ammoniacal salts of guano and of farmyard and other manures, and to liberate potash and ammonia, which are retained in the land, while the inexpensive lime salts pass into the land drainage.

Lime is used in agriculture in the form of quicklime, chalk (carbonate of lime), gypsum (sulphate of lime), marl, and shell-sand. For liming purposes gas-lime also is frequently employed, and, if well exposed to the air before being put on the land, may be used with safety and advantage.

6. *Magnesia.*—Magnesia is of but slight importance in manures; it occurs with potash in kainite and other potash salts, and the sulphate is sometimes used in making up artificial manures, but apparently without benefit.

7. *Silica.*—Silica is a constituent of the ashes of all plants, and occurs specially in large proportion in the straw of cereal crops. All soils contain such an abundance of silica that no necessity exists of supplying it artificially.

8. *Chlorine, Sulphuric Acid, and Oxide of Iron.*—These ash constituents are of little practical importance, inasmuch as most soils contain a sufficiency of them to meet the requirements of the crops usually cultivated on the farm. It may be observed, however, that chlorine has been found to be essential to plant life, and that iron is necessary for imparting to plants their green colour.

9. *Organic Matter or Humus.*—The importance of organic matter in manures was formerly much exaggerated. It has been conclusively proved that the carbon of which the bulk of the dry substance of all agricultural produce consists is derived from the carbonic acid of the atmosphere, and not from humus of the soil or the non-nitrogenous organic matters supplied in the manure. The organic matters present in dung in the shape of more or less decomposed or rotten straw exert a beneficial effect by improving the physical condition of both light and heavy land.

*Farmyard Manure.*—Farmyard manure is composed of the urine and solid excrements of animals collected in the stalls or yards, together with the straw used as litter. Its

[1] Containing ·297 of nitrogen, equal to ·36 of ammonia.
[2] Containing ·309 of nitrogen, equal to ·375 of ammonia. The whole manure containing ammonia in free state, ·046; in form of salts, ·057.

composition varies greatly, according to the quantity of straw used as an absorbent, the nature of the animals, the food they have consumed to produce it, the length of time and way in which it has been kept, &c. The analysis by Dr Voelcker of well-made farmyard manure from horses, cows, and pigs, given in Table IV., p. 509, will show its approximate composition.

This analysis shows that farmyard manure contains all the constituents, without exception, which are required by cultivated crops to bring them to perfection, and hence it may be called a perfect manure. Dung, it will be observed, contains a great variety of organic and inorganic compounds of various degrees of solubility, and this complexity of composition—difficult, if not impossible, to imitate by art—is one of the reasons which render farmyard manure a perfect as well as a universal manure.

The excrements of different kinds of animals vary in composition, and those of the same animal will vary according to the nature and quantity of the food given, the age of the animal, and the way it is generally treated. Thus a young animal which is growing needs food to produce bone and muscle, and voids poorer dung than one which is fully grown and only has to keep up its condition. The solid and liquid excrements differ much in composition, for, while the former contains a good deal of phosphoric acid, lime, magnesia, and silica, and comparatively little nitrogen, the urine is almost destitute of phosphoric acid, and abounds in alkaline salts and nitrogenous organic matters, which on decomposition yield ammonia. Unless, therefore, the two kinds of excrements are mixed, a perfect manure supplying all the needs of the plant is not obtained; care must accordingly be taken to absorb all the urine by the litter. Farmyard manure, it is well known, is much affected by the length of time and the way in which it has been kept. Fresh dung is soluble in water only to a limited extent, and in consequence it acts more slowly on vegetation, and the action lasts longer than when dung is used which has been kept some time; fresh dung is therefore generally used in autumn or winter, and thoroughly rotten dung in spring, when an immediate forcing effect is required.

The changes which farmyard manure undergoes on keeping are illustrated by the following table of analyses, by Professor Wolff of Hohenheim in Würtemberg, of farmyard manure in its different stages of decomposition:—

TABLE V.—*Average Percentage Composition of Farmyard Manure.*

| | Fresh. | Moderately Rotten. | Thoroughly Rotten. |
|---|---|---|---|
| Water | 71·0 | 75·0 | 79·0 |
| Organic matters | 24·6 | 19·2 | 14·5 |
| Ash | 4·4 | 5·8 | 6·5 |
| | 100·0 | 100·0 | 100·0 |
| Potash | ·52 | ·63 | ·50 |
| Soda | ·15 | ·19 | ·13 |
| Lime | ·57 | ·70 | ·88 |
| Magnesia | ·14 | ·18 | ·18 |
| Phosphoric acid | ·21 | ·26 | ·30 |
| Sulphuric acid | ·12 | ·16 | ·13 |
| Chlorine | ·15 | ·19 | ·16 |
| Silica | 1·25 | 1·68 | 1·79 |
| Nitrogen | ·45 | ·50 | ·58 |

These figures represent the composition of farmyard manure of rather poor quality. Well-made good dung, produced by fattening cattle fed upon a fair allowance of cake, roots, hay, and straw, on an average may be said to contain—

| | |
|---|---|
| Potash | ·50 per cent. |
| Phosphoric acid | ·53 ,, |
| Nitrogen | ·64 ,, |

Forty tons of dung, according to this estimate, contain in round numbers 448 lb of potash, 475 of phosphoric acid, and 573 of nitrogen.

During the fermentation of dung a large proportion of the non-nitrogenous organic matters disappears in the form of carbonic acid and water, while another portion is converted into humic acids which effectually fix the ammonia gradually produced from the nitrogenous constituents of the solid and liquid excrements. The mineral matters remain behind entirely in the rotten dung, if care be taken to prevent loss by drainage.

Well-fermented dung, it will be noticed from the preceding table, is more concentrated and consequently more efficacious than fresh farmyard manure. Neither fresh nor rotten dung contains any appreciable quantity of volatile ammonia, and hence there is no necessity for applying gypsum, dilute acid, green vitriol, or other substances recommended as fixers of ammonia. If dung is carted out into the field and spread out at once it may be left for weeks together before it is ploughed in without the slightest risk of sustaining loss in fertilizing matter by evaporation, for dung does not lose ammonia by evaporation on exposure to the air, and any mineral soluble salts will be washed into the soil where they are wanted. If, however, dung is kept for a length of time in shallow heaps, or in open straw-yards and exposed to rain, it loses by drainage a considerable proportion of its most valuable soluble fertilizing constituents.

With a view to ascertaining the loss in fertilizing substances which farmyard manure sustains when it is kept for a long time exposed in open yards to the deteriorating influences of rain, Dr Voelcker spread a weighed quantity of fresh dung of known composition in an open yard, and after a period of twelve months again weighed the dung and submitted it to analysis, when the results shown in Table VI. were obtained:—

TABLE VI.—*Showing the Loss which Dung sustains by Drainage in Open Yards.*

| | | Fresh Manure. | | After 12 Months' Exposure. |
|---|---|---|---|---|
| Weight of the manure | | 1652 | | 793·65 |
| Amount of water in the manure | | 1093 | | 622·80 |
| ,, dry substances | | 559 | | 170·85 |
| The dry substances consist of— | | | | |
| A. Soluble organic matters | | 40·07 | | 3·05 |
| B. Soluble mineral matters | | 23·43 | | 5·52 |
| C. Insoluble organic matters | | 423·67 | | 94·45 |
| D. Insoluble mineral matters | | 66·93 | | 66·93 |
| Whereof | | 559·00 | | 170·85 |
| A contains nitrogen | | 3·28 | | ·32 |
| Equal to ammonia | 3·98 | | ·39 | |
| B contains nitrogen | | 6·21 | | 3·56 |
| Equal to ammonia | 7·54 | | 4·25 | |
| Total amount of nitrogen in manure | | 9·49 | | 3·88 |
| Equal to ammonia | 11·52 | | 4·64 | |
| The whole manure contained— | | | | |
| Ammonia in free state | | ·55 | | ·0055 |
| Ammonia in the form of salts readily decomposed by quicklime | | 1·45 | | ·28 |
| Total amount of organic matters | | 466·64 | | 98·40 |
| ,, ,, mineral matters | | 92·36 | | 72·45 |

These tabulated results showed that the manure lost 69·8 per cent. of its fertilizing matters; or, in round numbers, two-thirds of the dung was wasted and only one-third left behind. Thus, after twelve months' exposure to the weather, nearly all the soluble nitrogen and 78·2 per cent. of the soluble mineral matters were lost by drainage. To prevent this loss, farmyard manure, as had been already pointed out, should, when possible, be carted into the field, spread out at once, and ploughed in at the convenience of the farmer. It is, however, not always practicable to apply farmyard manure just at the time it is made, and, as the manure heap cannot be altogether dispensed with, it is necessary to see how the manure may best be kept. For proper decomposition both air and moisture are requisite, while extreme dryness or too much water will arrest it. Farmyard manure is either prepared in dung-pits, which

are put in a separate place, or is accumulated under the animal in the feeding-boxes; of the two plans the latter is the better, the urine being more thoroughly absorbed, and, owing to the box manure being more compact through constant treading on it, air enters less freely and the decomposition goes on less rapidly, the volatile matters in consequence not being so readily lost. External agents, such as rain, wind, sun, &c., do not affect it as they would in the case of dung-pits. If farmyard manure must be stored in heaps, care should be taken to have the bottom and sides of the pit impermeable to water, and the bottom slightly inclined to allow any liquid manure which collects to run off into a tank below, from which, by means of a pump, it may be again poured over the heap. A concrete bottom for the pit is best, or, failing that, one of thick clay or well-beaten earth. The manure heap should be kept as compact as possible, and always moist. The advantage of farmyard manure lies, not only in its supplying all the constituents of plant food, but also in the improved physical condition of the soil through its application, as the land is kept porous, and air is allowed free access. While, however, farmyard manure has these advantages, experience has shown that artificial manures, properly selected to meet the requirements of the crops intended to be grown, due regard being had to the chemical composition of the soil, may be employed to greater advantage. In farmyard manure about two-thirds of the weight is water and one-third dry matter; a large bulk thus contains only a small proportion of fertilizing substances, and expense is incurred for carriage of much useless matter when dung has to be carted to distant fields. When a plentiful supply of good farmyard manure can be produced on the farm or bought at a moderate price in the immediate neighbourhood, it is economy to use it either alone or in conjunction with artificial manures; but when food is dear and fattening does not pay, or farmyard manure is expensive to buy, it will be found more economical to use artificial manures.

*Manures from Feeding Stuffs.*—The investigations of Messrs Lawes, Gilbert, and Mure have shown that, in estimating the value of animal manure, 90 per cent. of the nitrogen of the food may be reckoned to be recovered in the case of feeding cakes, pulse, and other highly nitrogenous feeding stuffs; 85 per cent. in the case of foods comparatively poor in nitrogen, such as cereals and roots; and less than 65 per cent. in the case of bulky feeding stuffs, such as hay and straw. As a source of manure, the value of fattening foods is greater the more nitrogen they contain. Practically speaking, the whole of the mineral constituents and about nine-tenths of the nitrogen of the food are recovered in the dung and urine. For the same weight of dry substance consumed, oxen void more manure than sheep, and sheep more than pigs. The composition of the different foods given to fattening animals being well known, it is easy to calculate the amounts of nitrogen, phosphoric acid, and potash of the food which will be recovered in the manure. Each constituent having its market value as a manuring constituent, the money value of the manure obtained from the consumption of a ton of any ordinary food of which the composition is known can be determined. Assuming ammonia to be worth 8d. per lb, potash 2d. per lb, and phosphate of lime 1d. per lb, the money value of the manure produced by the consumption of a ton of various foods is given by Mr Lawes in the following table (VII.), which also shows the general composition of the different foods as far as their manurial value is concerned.

In these estimates it is presumed that the manure can be put on the land without loss, but in practice some loss is unavoidable; it may be but slight, as, for instance, when sheep are fed on the land, or when the manure is made in feeding-boxes, but it will be considerable when the food has been consumed in open yards in a very rainy season. Allowances must thus be made for the circumstances under which the manure was produced.

*Artificial Manures.*—By some a distinction has been drawn between those manures which, like superphosphate, dissolved bones, &c., are manufactured in chemical works and those which are produced naturally, such as guano, nitrate of soda, &c. However, the term artificial manure is generally applied to all manures, natural or manufactured, which are not produced on the farm, as distinguished from farmyard manure and manure from purchased foods, which are essentially farm products. The value of all manures mainly depends on their chemical composition

As compared with farmyard manure, artificial manures have the disadvantage that they, unlike it, do not improve the physical condition of the soil. Artificial manures have, on the other hand, the advantage over farmyard manure that they can supply in a small compass, and even if used in small quantity, the needed nitrogen, phosphoric acid, and potash, &c., which crops require, and which farmyard manure has but in small proportion; they present the expensive fertilizing matters in a concentrated form, and by their application save expense in labour and carriage.

The following are the principal artificial manures in use:—

1. *Nitrogenous Manures.—Peruvian Guano.*—This is a natural manure, valuable on account of the ammonia, phosphoric acid, and potash it contains. It is the excrement, &c., of sea birds accumulated in parts where no rain falls. The earliest deposits found contained as much as 14 to 17 per cent. of ammonia, *e.g.*, Chinchas Island guano; those now (1882) imported seldom exceed 8 per cent., and generally vary from 4 to 8 per cent., of ammonia. In using guano it should be mixed with earth, &c., to prevent injury to the seeds or plants. Peruvian guano is also treated with sulphuric acid, which renders the phosphates soluble and fixes the ammonia, thereby preventing any loss of it; this constitutes dissolved guano, and is frequently sold upon a guarantee of 20 per cent. of soluble phosphates, 4 per cent. of insoluble phosphates, and 9 per cent. of ammonia. Peruvian guano is used as a top dressing for wheat and barley; in addition to insoluble phosphates, it contains soluble phosphates of the alkalies.

*Ammonia Salts.*—The principal one is sulphate of ammonia, largely produced in gas works by neutralizing gas liquor with sulphuric acid; it is usually sold on a basis of 24 to 25 per cent. of ammonia.

*Soot* is valuable on account of the sulphate of ammonia it contains; the percentage of ammonia varies from 1½ to 4.

*Nitrate of soda* is a natural deposit; it is greatly used as a top dressing for wheat and barley. It usually contains common salt, and when purified is sold on a basis of 95 per cent. of pure nitrate.

*Organic Nitrogenous Substances.*—Wool, hair, fish, flesh, horn, blood, rape cake, damaged cotton cake and other oil cakes. Wool refuse (shoddy), according to its quality, contains from 4 to 8 per cent. of nitrogen, flesh 14 to 15 per cent., blood (dried) 13 to 15 per cent., rape cake 4 to 5 per cent., linseed cake about 4 per cent., cotton cake (undecorticated) nearly 4 per cent., and cotton cake (decorticated) over 6 per cent. of nitrogen.

2. *Phosphatic Manures.*—(*a*) The following phosphatic minerals are used for the manufacture of superphosphate of various strengths, and of compound manures:—coprolites (Cambridge, Suffolk, and Bedfordshire), containing 50 to 55 per cent. of phosphate of lime; phosphorite (Spanish and Portuguese); apatite (Norwegian and Canadian), containing often as much as 80 per cent. phosphate of lime; South Carolina (land and river) phosphate, 52 to 56 per cent. phosphate of lime; French phosphate; Sombrero phosphate, 70 per cent. phosphate of lime; Curaçoa phosphate, 80 per cent. phosphate of lime; Navassa phosphate; Aruba phosphate, &c.

(*b*) *Bones.*—Raw bones, as ½ inch and ¼ inch bones; bonemeal; bone dust, having about 48 per cent. phosphate of lime and 4½ per cent. of ammonia; boiled bones, with 60 per cent. phosphate of lime and about 1·8 per cent. of ammonia; dissolved bones; bone ash, with 70 per cent. phosphate of lime; animal charcoal, with 70 to 80 per cent. phosphate of lime.

(*c*) *Phosphatic Guanos.*—Lacepede Island guano; Mexillones guano; Malden Island guano; Fanning Island guano; and many others varying in composition from 60 to 90 per cent. phosphate of lime.

3. *Saline Materials.*—Potash salts (chloride and sulphate); kainite, with 20 to 25 per cent. sulphate of potash, and also sulphate of magnesia and common salt; wood ashes, with about 10 per cent. of potash; common salt.

4. *Calcareous Manures.*—Lime, chalk, marl, gypsum, shell sand, gas lime, coal ashes, road scrapings, &c.

5. *Carbonaceous Manures.*—Sawdust, peat, sea-weed, vegetable refuse, &c.

6. *Special and Compound Manures.*—The basis of these is superphosphate, which is mixed with other manuring materials to meet the special requirements of particular crops and soils.

The foregoing remarks made on the application of manures to different kinds of crops may now in conclusion be summed up. Farmyard manure, in order to be most beneficial, should be applied as quickly as possible after it is made, the best time being in autumn or early winter. Nitrate of soda should be applied as a top dressing early in spring; its effect will be seen in the first season only. Ammonia salts, guano, dung, &c., are best applied to heavy land in autumn or winter, either before the seed is sown, or after the plant is fairly above ground, but in the case of light land early in spring. The effect of bones in the various form of dissolved bones, bone dust, raw bones, &c., will last two or more seasons according to the quantities used and their respective solubility. Lastly, it may be observed that the presence of lime is essential to the economical use of manures.

As regards cereal crops, it has been found that mineral manures alone, whether simple or complex, do not produce appreciable increase of crop, but that nitrogenous manures, whether as ammonia salts, nitrate of soda, or farmyard manure, greatly benefit the crop; that nitrate of soda does rather better than ammonia salts; and that, while on fairly heavy land farmyard manure will yield good crops, the best results are obtained by using mineral and nitrogenous manures together. On clay soils a top dressing of nitrate of soda often answers all practical purposes, but on light soils nitrate of soda or ammonia salts should not be used without mineral manures, while it is advisable even on heavy land to use superphosphate as well.

For root crops, on cold clays nothing answers so well as mineral superphosphate alone, but on light land dissolved bones, bone dust precipitated phosphate, or a compound artificial manure will be found to be much preferable to superphosphate. Bone meal mixed with mineral superphosphate makes, for instance, a good manure for roots; for mangolds Peruvian guano and common salt in addition are useful, and for potatoes potash salts with phosphatic and nitrogenous manures.

For pasture land the use of artificial manures is, as a rule, not economical; nitrogenous manures raise the quantity and phosphatic and potash manures improve the quality of the herbage, while, for worn-out pastures, potash with dissolved bones or superphosphate or superphosphate and guano will do much good. The most economical way of manuring pasture land is to apply farmyard manure liberally, or feed it off with cattle, giving cotton cake in addition.

The employment of artificial manures in a judicious manner has shown the occupier of land that it is not necessary for him to be bound down to any system of rotation of crops which may be practised in his particular district, but that he has the means of pursuing the course of cropping, system of manuring, and general management of his farm which will yield him the best returns. No more striking instance of this could be put forward than the experience of Mr Prout, who at Sawbridgeworth, Herts, has grown with much success cereal crops, year after year, on heavy clay land, selling the whole of the growing crops, and restoring the fertility of the soil by artificial manures. The land was purchased in 1861, and up to the present time (1882) the crops have been as good as ever, and the land has not been deteriorated, but on the other hand improved, by continuous corn growing. The experiments of Messrs Lawes and Gilbert at Rothamsted and of Dr Voelcker at Woburn have been thus verified on a large scale in the experience of Mr Prout, and have shown beyond all possibility of doubt the efficacy and economy of a liberal use of artificial manures. (A. V.)

MANUSCRIPTS, Ancient. See Diplomatics and Palæography.

MANUTIUS. I. Aldus Manutius (1450–1515). Teobaldo Mannucci, better known as Aldo Manuzio, the founder of the Aldine press, was born in 1450 at Sermoneta in the Papal States. He received a scholar's training, studying Latin at Rome under Gasparino da Verona, and Greek at Ferrara under Guarino da Verona. Having qualified himself for the career of a humanist, according to the custom of the century, he went in 1482 to reside at Mirandola with his old friend and fellow-student, the illustrious Giovanni Pico. There he stayed two years, prosecuting his studies in Greek literature. Before Pico removed to Florence, he procured for Aldo the post of tutor to his nephews Alberto and Lionello Pio, princes of Carpi. To Alberto Pio the world owes a debt of gratitude, inasmuch as he supplied Aldo with funds for starting his printing press, and gave him lands at Carpi. It was Aldo's ambition to secure the literature of Greece from further accident by committing its chief masterpieces to type; and the history of his life is the record of the execution of this gigantic task. Before his time four Italian towns had won the honours of Greek publications:—Milan, with the grammar of Lascaris, Æsop, Theocritus, a Greek Psalter, and Isocrates, between 1476 and 1493; Venice, with the *Erotemata* of Chrysoloras in 1484; Vicenza, with reprints of Lascaris's grammar and the *Erotemata*, in 1488 and 1490; Florence, with Alopa's Homer, in 1488. Of these works, only three, the Milanese Theocritus and Isocrates and the Florentine Homer, were classics. Aldo selected Venice as the most appropriate station for his labours. He settled there in 1490, and soon afterwards gave to the world editions of the *Hero and Leander* of Musæus, the *Galeomyomachia*, and the Greek Psalter. These have no date; but they are the earliest

tracts issued from his press, and are called by him "Precursors of the Greek Library."

At Venice Aldo gathered an army of Greek scholars and compositors around him. His trade was carried on by Greeks, and Greek was the language of his household. Instructions to type-setters and binders were given in Greek. The prefaces to his editions were written in Greek. Greeks from Crete collated MSS., read proofs, and gave models of calligraphy for casts of Greek type. Not counting the craftsmen employed in merely manual labour, Aldo entertained as many as thirty of these Greek assistants in his family. His own industry and energy were unremitting. In 1495 he issued the first volume of his Aristotle. Four more volumes completed the work in 1497–98. Nine comedies of Aristophanes appeared in 1498. Thucydides, Sophocles, and Herodotus followed in 1502; Xenophon's *Hellenics* and Euripides in 1503; Demosthenes in 1504. The troubles of Italy, which pressed heavily on Venice at this epoch, suspended Aldo's labours for a while. But in 1508 he resumed his series with an edition of the minor Greek orators; and in 1509 appeared the lesser works of Plutarch. Then came another stoppage. The league of Cambray had driven Venice back to her lagoons, and all the forces of the republic were concentrated on a struggle to the death with the allied powers of Europe. In 1513 Aldo reappeared with Plato, which he dedicated to Leo X. in a preface eloquently and earnestly comparing the miseries of warfare and the woes of Italy with the sublime and tranquil objects of the student's life. Pindar, Hesychius, and Athenæus followed in 1514.

These complete the list of Aldo's prime services to Greek literature. But it may be well in this place to observe that his successors continued his work by giving Pausanias, Strabo, Æschylus, Galen, Hippocrates, and Longinus to the world in first editions. Omission has been made of Aldo's reprints, in order that the attention of the reader might be concentrated on his labours in editing Greek classics from MSS. Other presses were at work in Italy; and, as the classics issued from Florence, Rome, or Milan, Aldo took them up, bistowing in each case fresh industry upon the collation of codices and the correction of texts. Nor was the Aldine press idle in regard to Latin and Italian classics. The *Asolani* of Bembo, the collected writings of Poliziano, the *Hypnerotomachia Poliphili*, Dante's *Divine Comedy*, Petrarch's poems, a collection of early Latin poets of the Christian era, the letters of the younger Pliny, the poems of Pontanus, Sannazzaro's *Arcadia*, Quintilian, Valerius Maximus, and the *Adagia* of Erasmus were printed, either in first editions, or with a beauty of type and paper never reached before, between the years 1495 and 1514. For these Italian and Latin editions Aldo had the elegant type struck which bears his name. It is said to have been copied from Petrarch's handwriting, and was cast under the direction of Francesco da Bologna, who has been identified by Panizzi with Francia the painter.

Aldo's enthusiasm for Greek literature was not confined to the printing-room. He burned with a humanist's enthusiasm for the books he printed; and we may well pause astonished at his industry, when we remember what a task it was in that age to prepare texts of authors so numerous and so voluminous from MSS. Whatever the students of this century may think of Aldo's scholarship, they must allow that only vast erudition and thorough familiarity with the Greek language could have enabled him to accomplish what he did. In his own days Aldo's learning won the hearty acknowledgment of ripe scholars. To his fellow workers he was uniformly generous, free from jealousy, and prodigal of praise. His stores of MSS. were as open to the learned as his printed books were liberal given to the public. While aiming at that excellence of typography which renders his editions the treasures of the book-collector, he strove at the same time to make them cheap. We may perhaps roughly estimate the current price of his pocket series of Greek, Latin, and Italian classics, begun in 1501, at 2s. per volume of our present money. The five volumes of the Aristotle cost about £8. His great undertaking was carried on under continual difficulties, arising from strikes among his workmen, the piracies of rivals, and the interruptions of war. When he died, bequeathing Greek literature as an inalienable possession to the world, he was a poor man. In order to promote Greek studies, Aldo founded an academy of Hellenists in 1500 under the title of the New Academy. Its rules were written in Greek. Its members were obliged to speak Greek. Their names were Hellenized, and their official titles were Greek. The biographies of all the famous men who were enrolled in this academy must be sought in the pages of Didot's *Alde Manuce*. It is enough here to mention that they included Erasmus and the English Linacre.

In 1499 Aldo married Maria, daughter of Andrea Torresano of Asola. Andrea had already bought the press established by Nicholas Jenson at Venice. Therefore Aldo's marriage combined two important publishing firms. Henceforth the names Aldus and Asolanus were associated on the title pages of the Aldine publications; and after Aldo's death in 1515, Andrea and his two sons carried on the business during the minority of Aldo's children. The device of the dolphin and the anchor, and the motto *festina lente*, which indicated quickness combined with firmness in the execution of a great scheme, were never wholly abandoned by the Aldines until the expiration of their firm in the third generation.

II. Paulus Manutius (1512–1574). By his marriage with Maria Torresano, Aldo had three sons, the youngest of whom, Paolo, was born in 1512. He had the misfortune to lose his father at the age of two. After this event his grandfather and two uncles, the three Asolani, carried on the Aldine press, while Paolo prosecuted his early studies with unremitting industry at Venice. Excessive application hurt his health, which remained weak during the rest of his life. At the age of twenty-one he had acquired a solid reputation for scholarship and learning. In 1533 Paolo undertook the conduct of his father's business, which had latterly been much neglected by his uncles. In the interregnum between Aldo's death and Paolo's succession (1514–33) the Asolani continued to issue books, the best of which were Latin classics. But, though their publications count a large number of first editions, and some are works of considerable magnitude, they were not brought out with the scholarly perfection at which Aldo aimed. The Asolani attempted to perform the whole duties of editing, and to reserve all its honours for themselves, dispensing with the service of competent collaborators. The result was that some of their editions, especially their Æschylus of 1518, are singularly bad. Paolo determined to restore the glories of the house, and in 1540 he separated from his uncles. The field of Greek literature having been well-nigh exhausted, he devoted himself principally to the Latin classics. He was a passionate Ciceronian, and perhaps his chief contributions to scholarship are the corrected editions of Cicero's letters and orations, his own epistles in a Ciceronian style, and his Latin version of Demosthenes. Throughout his life he combined the occupations of a student and a printer, winning an even higher celebrity in the former field than his father had done. Four treatises from his pen on Roman antiquities deserve to be commemorated for their erudition no less than for the elegance of their Latinity. Several Italian cities contended for the possession of so

rare a man; and he received tempting offers from the Spanish court. Yet his life was a long struggle with pecuniary difficulties. To prepare correct editions of the classics, and to print them in a splendid style, has always been a costly undertaking. And, though Paolo's publications were highly esteemed, their sale was slow. In 1556 he received for a time external support from the Venetian Academy, founded by Federigo Badoaro. But Badoaro failed disgracefully in 1559, and the academy was extinct in 1562. Meanwhile Paolo had established his brother, Antonio, a man of good parts but indifferent conduct, in a printing office and book shop at Bologna. Antonio died in 1559, having been a source of trouble and expense to Paolo during the last four years of his life. Other pecuniary embarrassments arose from a contract for supplying fish to Venice, into which Paolo had somewhat strangely entered with the Government. In 1561 Pope Pius IV. invited him to Rome, offering him a yearly stipend of 500 ducats, and undertaking to establish and maintain his press there. The profits on publications were to be divided between Paolo Manuzio and the apostolic camera. Paolo accepted the invitation, and spent the larger portion of his life, under three papacies, with varying fortunes, in the city of Rome. Ill health, the commercial interests he had left behind at Venice, and the coldness shown him by Pope Pius V., induced him at various times and for several reasons to leave Rome. But of these excursions it is not necessary to take particular notice. As was natural, his editions after his removal to Rome were mostly Latin works of theology and Biblical or patristic literature.

Paolo married his wife, Caterina Odoni, in 1546. She brought him three sons and one daughter. His eldest son, the younger Aldus, succeeded him in the management of the Venetian printing house when his father settled at Rome in 1561. Paolo had never been a strong man, and his health was overtaxed with studies and commercial worries. Yet he lived into his sixty-second year, and died at Rome in 1574.

III. Aldus Manutius, Junior (1547–1597). The younger Aldo, born in the year after his father Paolo's marriage, cradled in scholarship, and suckled as it were with printer's ink, proved what is called an infant prodigy. When he was nine years old, his name was placed upon the title page of the famous *Eleganze della lingua Toscana e Latina*. What his share was in that really excellent selection cannot be ascertained; but it is hardly possible that a boy of nine could have compiled it without assistance. The *Eleganze* was probably a book made for his instruction and in his company by his father. In 1561, at the age of fourteen, he produced a work upon Latin spelling, called *Orthographiæ Ratio*. During a visit to his father at Rome in the next year, he was able to improve this treatise by the study of inscriptions, and in 1575 he completed his labours in the same field by the publication of an *Epitome Orthographiæ*. Whether Aldo was the sole composer of the work on spelling, in its first edition, may be doubted; but he appropriated the subject and made it his own. Probably his greatest service to scholarship is this analysis of the principles of orthography in Latin.

Aldo remained at Venice, prosecuting studies in literature and superintending the Aldine press. But in these days of early manhood he was not satisfied with the career of scholarship and business. At one time he hankered after the more worldly honours of the law, at another he built a country house at Asola, perplexing his father, who had given him too easy independence, with the humours of his age. A marriage came to make these matters straight. The Giunta family had been steadily rising in the world as printers, in proportion as the Aldi declined through want of concentration upon commerce. In 1572 Aldo took for his wife Francesca Lucrezia, daughter of Bartolommeo Giunta, and great-grandchild of the first Giunta, who founded the famous printing house in Venice. This was an alliance which augured well for the future of the Aldines, especially as the young husband, in the midst of distractions, had recently found time to publish a new revised edition of Velleius Paterculus. Two years later the death of his father at Rome placed Aldo at the head of the firm. In concert with his new relatives, the Giunta, he now edited an extensive collection of Italian letters, and in 1576 he appeared again before the public as a critic with his commentary upon the *Ars Poetica* of Horace. Printing, in this case, as in the case of his father, went hand in hand with original authorship. About the same time, that is to say, about the year 1576, he was appointed professor of literature to the Cancelleria at Venice. The Aldine press continued through this period to issue books, but none of signal merit; and in 1585 Aldo determined to quit his native city for Bologna, where he occupied the chair of eloquence for a few months. In 1587 he left Bologna for Pisa, and there, in his quality of professor, he made the curious mistake of printing Alberti's comedy *Philodoxius* as a work of the classic Lepidus. Sixtus V. drew him in 1588 from Tuscany to Rome; and at Rome he hoped to make a permanent settlement as lecturer. But his public lessons were ill attended, and he soon fell back upon his old vocation of publisher under the patronage of a new pope, Clement VIII. In the tenth year of his residence at Rome, that is, in 1597, he died, leaving children, but none who cared or had capacity to carry on the Aldine press. Aldo himself, though a precocious student, a scholar of no mean ability, and a publisher of some distinction, was the least remarkable of the three men who gave books to the public under the old Aldine ensign. Times had changed in Italy since Aldo the elder conceived the great idea of reaping for the press the harvest of Greek literature. And his posterity had changed with the times for the worse. This does not of necessity mean that we should adopt Scaliger's critique of the younger Aldo without reservation. Scaliger called him "a poverty-stricken talent, slow in operation; his work is very commonplace; he aped his father." What is true in this remark lies partly in the fact that scholarship in Aldo's days had flown beyond the Alps, where a new growth of erudition, on a basis different from that of the Italian Renaissance, had begun.

Renouard's *Annales de l'Imprimerie des Aldes*, Paris, 1834, and Didot's *Alde Manute*, Paris, 1873, contain all necessary information regarding the lives of the Manutii and their publications. (J. A. S.)

MANZONI, Alessandro Francesco Tommaso Antonio (1785–1873), founder of the romantic school in Italian literature, was born at Milan, March 7, 1785. Don Pietro, his father, then about fifty, represented an old family settled near Lecco, but originally feudal lords of Barzio, in the Valsassina, where the memory of their violence is still perpetuated in a local proverb, comparing it to that of the mountain torrent. The poet's maternal grandfather, Cesare Beccaria, was a well-known author, and his mother Giulia a woman of some literary ability. Manzoni's intellect was slow in maturing, and at the various colleges where his school days were passed he ranked among the dunces. At fifteen, however, he developed a passion for poetry, and wrote two sonnets of considerable merit. On the death of his father in 1805, he joined his mother at Auteuil, and spent two years there, mixing in the literary set of the so-called "idealogues," philosophers of the 18th century school, among whom he made many friends, notably Claude Fauriel. There too he imbibed the negative creed of Voltairianism, and only after

his marriage, and under the influence of his wife, did he exchange it for that fervent Catholicism which coloured his later life. In 1806–7, while at Auteuil, he first appeared before the public as a poet with two pieces, one entitled *Urania*, in the classical style, of which he became later the most conspicuous adversary, the other an elegy in blank verse, on the death of Count Carlo Imbonati, from whom, through his mother, he inherited considerable property, including the villa of Brusuglio, thenceforward his principal residence.

Manzoni's marriage in 1808 to Henriette Blondel, daughter of a Genevese banker, proved a most happy one, and he led for many years a retired domestic life, divided between literature and the picturesque husbandry of Lombardy. His intellectual energy at this period was devoted to the composition of the *Inni Sacri*, a series of sacred lyrics, and a treatise on Catholic morality, forming a task undertaken under religious guidance, in reparation for his early lapse from faith. In 1818 he had to sell his paternal inheritance, as his affairs had gone to ruin in the hands of a dishonest agent. The beautiful villa Il Galeotto, where he had spent his childish years amid the scenery he afterwards immortalized, then passed from his hands, to his great regret. His characteristic generosity was shown on this occasion in his dealings with his peasants, who on settling their accounts were found heavily indebted to him. He not only cancelled on the spot the record of all sums owing to him, but bade them keep for themselves the whole of the coming maize harvest.

In 1819 Manzoni published his first tragedy, *Il Conte di Carmagnola*, which, boldly violating all classical conventionalisms, excited a lively controversy. It was severely criticized in the *Quarterly Review*, in an article to which Goethe replied in its defence, "one genius," as Count de Gubernatis remarks, "having divined the other." The death of Napoleon in 1821 inspired Manzoni's powerful stanzas *Il Cinque Maggio*, the most popular lyric in the Italian language.

The political events of that year, and the imprisonment of many of his friends, weighed much on Manzoni's mind, and the historical studies in which he sought distraction during his subsequent retirement at Brusuglio, suggested his great work. Round the episode of the *Innominato*, historically identified with Bernardino Visconti, *I Promessi Sposi* began to grow into shape, and was completed in September 1822. The work when published, after revision by friends in 1825–27, at the rate of a volume a year, at once raised its author to the first rank of literary fame. In the interim of its composition in 1822, Manzoni published his second tragedy *Adelchi*, turning on the overthrow by Charlemagne of the Lombard domination in Italy, and containing many veiled allusions to the existing Austrian rule.

With these works Manzoni's literary career was practically closed. The end of the poet's long life was saddened by domestic sorrows. The loss of his wife in 1833 was followed by that of several of his children, and of his mother, to whom he was fondly attached. In 1837 he married his second wife, Teresa Borri, widow of Count Stampa, whom he also survived, while of nine children born to him in his two marriages, all but two preceded him to the grave. The death of his eldest son, Pier Luigi, on April 28, 1873, was the final blow which hastened his end; he fell ill immediately, and died of cerebral meningitis, May 22, aged eighty-eight. His country mourned him with almost royal pomp, and his remains, after lying in state for some days, were followed to the cemetery of Milan by a vast cortége, including the royal princes and all the great officers of state. But his noblest monument was Verdi's *Requiem*, specially written to honour his memory.

Manzoni's position in literature is unique; for, while the romantic Renaissance produced in other countries a galaxy of genius, in Italy it remained embodied in him alone, since none of his disciples came near enough to be classed with him. Scott declared *I Promessi Sposi* the finest novel ever written; and, if we take as our standard loftiness of aim combined with ingenuous simplicity of style, and Titianesque power of character painting relieved by an undercurrent of subtle irony giving point to every trivial incident, we need scarcely dispute his verdict. It occupies the same place in Italian as *Don Quixote* in Spanish literature, overshadowing in similar fashion the whole field of subsequent fiction. Manzoni's poetry cannot be classed so high, and, despite its nervous diction and epigrammatic intensity of thought, it is as a great master of Italian prose that he will go down to posterity.

Of exalted private character, Manzoni furnishes an almost solitary instance of a poet whose life contains no note of discord with the loftiest standard presented by his works. The highest genius, disciplined by still higher moral self-control, produced in him the rare spectacle of a perfect equilibrium of forces in a powerful mind. His presence was impressive, and his speech, though retarded by a slight impediment, so full of wisdom that Tommaseo declared he had learned more from his conversation than from all the books he had ever read. At the same time he had that exquisite courtesy in listening which gave to those who addressed him the sense of having spoken well. No man ever attained to greater honour from his contemporaries, or sought it less, and few have joined such rare intellectual gifts to so much gracious humility of mind and manners. His warmth of affection, tenderness of sympathy, and universal benevolence endeared him to his friends and fellow-citizens, while by his countrymen at large he was revered as the sage and patriarch of Italian letters.

In addition to the works already named, he wrote *La Storia della Colonna Infame*, and a small treatise on the Italian language. *I Promessi Sposi*, laboriously revised by the author in accordance with the Tuscan idiom, has gone through 118 Italian, 19 French, 17 German, and 10 English editions.

Biographical sketches of Manzoni have been recently published by Cesare Cantù (1882), Benedetto Prina, Giulio Carcano, Angelo de Gubernatis, Antonio Stoppani (his early years), and others. Some of his letters have been published by Giovanni Sforza, and a work entitled, *Commento Storico su I Promessi Sposi*, by Cesare Cantù. See also the essay on "Fauriel" in Sainte-Beuve's *Portraits Contemporains*, vol. iv.

MAP. 1. *First Essays in Map-making.*—As each man stands in the centre of his horizon and the portion of the earth's surface which lies within his range of vision has the appearance of a disk, the whole world was in ancient times conceived as a disk surrounded by the sea. It was consequently not uncommon for a people to imagine—as was the case we know with the Chinese, the Hindus, the Chaldæans, the Jews, the Arabs, and even the ancient Peruvians—that it occupied the middle part of the world. The wider a people's range of vision, the wider was the disk of the world represented. A circular surface is thus the simplest form for a *mappa mundi* or map of the world; and it is met with both in antiquity and in the Middle Ages. The extent of the circle of vision depends among uncivilized peoples on their way of life. Wandering tribes have seen more of the world than settled tribes; and hunters, fishers, and seamen make the widest excursions. Among them consequently we find the beginnings of map-making; and Eskimo, Indians, and Polynesians, for example, show in this matter astonishing quickness of apprehension, while among the settled Negro tribes, on the other hand, there are no maps. A map drawn by an Eskimo woman enabled Sir Edward Parry to discover Fury and Hecla Strait; M'Clintock during his endeavours to clear up the fate of the Franklin expedition repeatedly got the Eskimo to draw coast-maps of the Arctic lands; and many similar instances are given by Andree, "Beginnings of Cartography," *Globus*, xxxi. pp. 24–27, 37–43.

Turning to civilized peoples, it is among the Egyptians that we find the earliest recorded examples of cartographic representation. Apollonius of Rhodes (born 230 B.C.) reports in his *Argonautica* (iv. 279) that the Egyptians of Colchis, a colony dating from the time of Ramses II. (?), had preserved as heirlooms certain wooden tablets (*κύρβεις*) on which land and sea, roads and highways, were accurately indicated; Eustathius, in his commentary

on Dionysius Periegetes, mentions that Sesostris the Egyptian king caused route-maps to be prepared; and Strabo also refers to certain old maps in the library of Eratosthenes in which Meroe and the south end of the peninsula of India were placed on the same parallel of latitude. These statements have been confirmed by the actual discovery of such maps and plans on old Egyptian papyrus-rolls. Birch has, for instance, identified a drawing on a papyrus in the Turin Museum as the topographical map of a gold-mining district in Nubia. The perspective in this case is very childish: in order to show that the road leads between two mountain-chains, the mountains on one side of the road are inverted (comp. Lepsius, *Urkundenbuch*, pl. xxii.). This map is one thousand years older than that of Anaximander, who was considered by the Greeks as the inventor of cartography. On another sheet appears a representation of the victorious return of Sethos I. (1443–1392 B.C.) from Asia, showing the road from Pelusium by Leontopolis to Heroopolis, Lake Timsah with fish in it, the canal from the Nile with crocodiles, and at Heroopolis a bridge over the canal. Similar picture-maps were discovered by Layard in Assyria (*Nineveh and Babylon*, p. 231 *sq.*, 1867). The ancient Babylonians have also the high distinction of having divided space and time in a way that allowed scientific measurements to be made after the still customary method. It was they who originated the division of the ecliptic into twelve signs and later into 360 degrees; and the division of the circle into 360 degrees with 60 minutes to the degree and 60 seconds to the minute, as well as the corresponding division of the hour, was the outcome of their sexagesimal system of numeration. This method of division was introduced among the Greeks by Hipparchus (150 B.C.), and obtained general currency through the geographer Ptolemy (150 A.D.). By this means were provided the elements necessary for the astronomical determination of geographical position. Among the Egyptians and Babylonians map-making remained in its first infantile stage; its scientific development was received at the hands of the Greeks.

2. *Development of Map-making among the Greeks.*— In Homer the "circumfluent ocean" represents the horizon which bounds the disk of the world; the scientific treatment of geography and map-making has its origin among the Ionic Greeks of Asia Minor. Anaximander, a pupil of Thales (about 560 B.C.), sketched the first map (*γεωγραφικὸς πίναξ*), and was the first who sought to determine the compass of the earth (the world-disk) and the sea. As the Greeks gradually extended their journeys as far as India in the East and the Atlantic in the West, the conviction gained ground that the world-disk could not be bounded by a regular circular outline. About one hundred years after Anaximander, Democritus of Abdera ventured to draw a new map on the basis of his own observations (for in his extensive wanderings he had been as far as Persia and perhaps even India); and in opposition to the circular form of the Ionians he gave the world an oblong shape, and taught that from east to west it was half as long again as from north to south. Although after the time of Aristotle the tabular or flat-surface theory of the figure of the earth was expelled by the spherical or globe theory, the portion of the earth's surface which was really known retained the same oblong shape which it had with Democritus; and hence we still speak of longitude and latitude, that is, length and breadth. It was on this basis also that the far-travelled Hecatæus of Miletus, who wrote his *Γῆς περίοδος* between 520 and 500 B.C., drew up his map; for the representation of the world on a brazen tablet, which was shown by Aristagoras, tyrant of Miletus, to King Cleomenes of Sparta, was probably nothing else than the world-map of Hecatæus. The first application of astronomy to geography was made by the famous Arctic navigator Pytheas of Marseilles, about 326 B.C.; it is from him that we obtain the first observation of latitude, and, what is of some importance, this is for Marseilles. His voyage to the extreme North (Thule) was undertaken partly for the purpose of satisfying himself in regard to the figure and size of the earth. Dicæarchus of Messana in Sicily, a pupil of Aristotle's (310 B.C.), made the first approach to a projection. He divided the inhabited (*i.e.*, the known) world, which he reckoned to be one and a half times as long as it was broad, into a northern and a southern half by means of what he considered a straight line drawn from the pillars of Hercules, through Sicily, the Peloponnesus, Caria, Lycia, Pamphylia, Cilicia, and across the Taurus to the Imaus (Himalaya). He thus drew the first parallel of latitude, and upon this basis he prepared maps which were to be publicly exhibited in a hall (Agathem., § 5; Strabo, p. 105). The name *διάφραγμα τῆς οἰκουμένης*, *i.e.*, partition of the inhabited world, was given to the base-line. For the next material improvement we are indebted to the famous astronomer and geographer Eratosthenes of Cyrene, the keeper of the Alexandrian library (276–196 B.C.). He was the first to make a rational geodetic measurement for the purpose of determining the size of the earth, and he collected in his *Γεωγραφικά* the whole geographical learning of his time. This work has unfortunately been lost, but from the numerous fragments that have been preserved, especially by Strabo, it is possible to form an idea of this the first systematic geography. Starting with the spherical form and the size of the world, it gave a description of the *οἰκουμένη*, discussed the space relations of the world-island, and estimated its extent in longitude and latitude. On the basis of the diaphragm of Dicæarchus, the course of which was more precisely indicated, a series of seven parallels and as many meridians cutting the diaphragm at right angles were drawn, and by this means the inhabited world was divided to the north and the south of the diaphragm into a certain number of regular divisions to which the name of sphragidia or seals was given. Then follows a description of the countries in the several "seals," beginning with India. In this arrangement we may recognize the first attempt to construct a network or system of degrees. As numerous data in regard to distances were already at his command, Eratosthenes greatly improved on the old maps in the matter of correctness; but, as the number of astronomical determinations of latitude was still small, and the intervals between the parallels and the meridians were unequal and conditioned by the available data in regard to distance, his network of lines was far from being an exact mathematical system. Hipparchus of Nicæa in Bithynia, the greatest astronomer of the ancient world (about 150 B.C.), consequently rejected the geography of Eratosthenes because it only partially utilized the abundant resources provided by the high development of contemporary mathematics and astronomy. Instead of the uncertain estimates of distance and direction furnished by travellers, only astronomical determinations of latitude and longitude should, he maintained, have been employed. He does not appear, however, to have himself written a geography or constructed a map. About the same time Crates of Mallus made the first globe. On this he extended the Atlantic Ocean southward to the south pole, placed a corresponding ocean on the other hemisphere, and, in the belief that the torrid zone could be occupied by nothing but water, ran an Oceanic belt along the line of the equator (fig. 1). In the four segments thus produced he set four semicircular land-areas, only one of which was known to the ancient world. This systematic figure maintained its place down into the Middle Ages, as

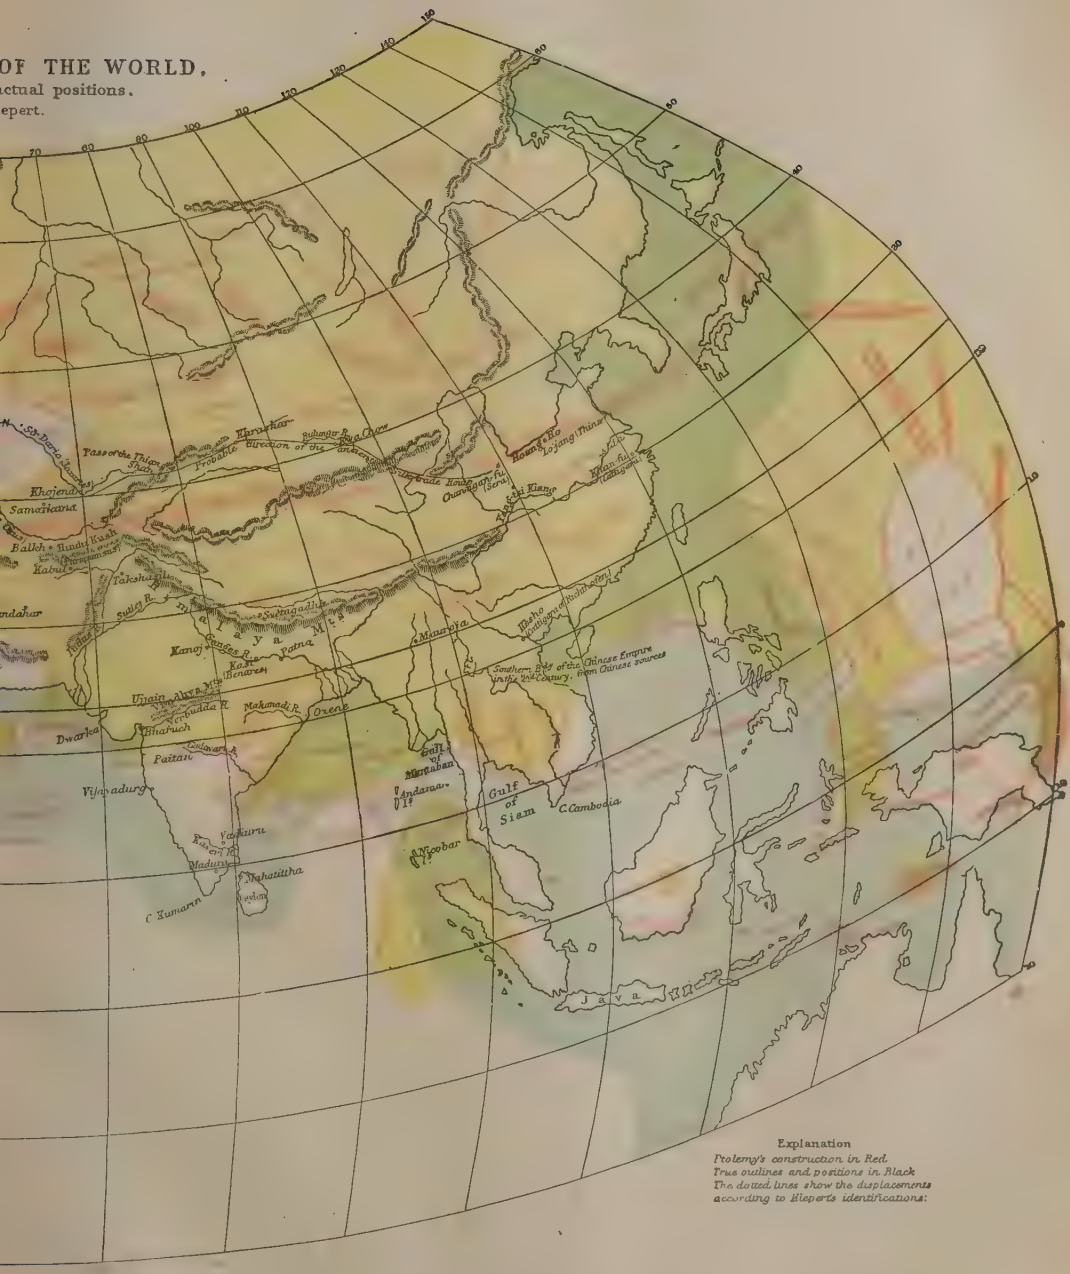
OF THE WORLD,
actual positions.
epert.



Explanation
Ptolemy's construction in Red.
True outlines and positions in Black.
The dotted lines show the displacements
according to Kiepert's identifications.

appears from the ornamentation of the globe that forms part of the insignia of royalty.

Marinus of Tyre (about 150 A.D.) was the first who sought to give effect to the demand made by Hipparchus for a trustworthy representation of the countries of the world. His work unfortunately has been lost; and we know of its existence only from his successor Claudius Ptolemy. Without Marinus, however, Ptolemy's work would have been impossible; and neither of them was able really to carry out Hipparchus's idea of determining the latitude and longitude for every place; for observations of latitude were known only for Marseilles, Syene, Alexandria, Rhodes, and perhaps a few other places, and all other positions were obtained by reducing distances to degrees. The determination of longitudes was even more difficult. Ptolemy possessed only the contemporary observation of the lunar eclipse in Arbela and Carthage of the year 331 B.C., from which he calculated a difference of meridian of 45° 10′ instead of 34° 2′. The longer axis of the Mediterranean was consequently a third too great, 62 degrees of the meridian being assumed instead of 41⅔, and from this there resulted an exaggeration of all the Mediterranean countries, which was corrected only by the compass-maps of the later Middle Ages. Ptolemy, however (availing himself of the stereographic projection devised by Hipparchus), corrected an important blunder which Marinus had committed through neglecting to take account of the sphericity of the earth and constructing a rectangular system of degrees. Like Marinus, he counted his meridians from the Canaries (the Fortunate Islands). No maps appear to have been drawn by Ptolemy himself; those to be found in the oldest editions of his work are by Agathodæmon (a mathematician of the 5th (?) century after Christ), though accurately based, it is true, on Ptolemy's data. The oldest MS. of Ptolemy is that found in the Vatopedi monastery of Mount Athos, and published by Victor Langlois in 1867 along with careful reproductions of the maps. It dates from the 12th or 13th century. Besides the exaggeration of the Mediterranean, the greatest blunders of Ptolemy are the following:—the European continent between the Black Sea and the Baltic is too narrow; India is not represented as a peninsula; Ceylon (Taprobane) is made much too large; and the Indian Ocean is bounded by lands towards the south (Plate VII.). But in spite of all this the scientific method pursued in the representation was perfectly correct. It was not till the Renaissance that a return was made to the rational treatment of cartography inaugurated by Ptolemy; and he then became the teacher of the modern world.

3. *Map-making among the Romans.*—The Romans contributed nothing to the development of the scientific method of the Greeks, and did not apply astronomy to the purposes of cartography. They valued maps according to their practical utility as implements of political administration; and they accordingly attached most importance to the route-map, from which they could learn the roads, the stations, and the distances. If we may judge by the few examples which have been preserved, these sketches may, distortions apart, be compared with our railway maps. Cicero and Seneca mention general and topographical maps. In their time the military routes were already divided into stages, furnished with milestones, and consequently measured. During the reign of Augustus a survey of the whole Roman empire was carried out. The routes were marked on parchment rolls for the purposes of military and civil administration. A map of the world was painted in a portico at Rome; a map of Italy was to be seen in the temple of Tellus. Particularly celebrated was Agrippa's map. Pliny must plainly have been in possession of maps to keep himself right in regard to the great number of names which he records. A map of the Roman empire was drawn up under Domitian. The emperors of the 2d, 3d, and 4th centuries caused maps to be constructed and painted on the walls of public buildings in the cities of Gaul, as for example in Augustodunum (Autun); but of this class unfortunately none has been preserved. The only Roman map, indeed, of the imperial epoch which has come down to us is the *Tabula Peutingeriana*, which takes its modern name from Conrad Peutinger of Augsburg, who possessed it in the 16th century. It is now preserved in the Imperial Library of Vienna. Its origin as a map goes back at least to the 3d century of the Christian era,—to the time, that is, of Alexander Severus; but the actual copy is not older than the 13th century. It consists of twelve folio sheets of parchment, which originally formed one long strip. It has been published by Scheyb (1753) and Mannert (1834), and in excellent facsimile by Desjardins (1869, &c.). That the original of this remarkable map was of a circular shape has been satisfactorily proved, the pattern followed being that of the map of the world in the portico of the Campus Agrippæ, which for centuries retained the rank of a model. Probably, however, such an *orbis pictus* was not exactly round, but rather oval. In its construction effect was also given to the opinion current from the time of Herodotus that the extent of the inhabited world was greater from east to west than from north to south. From this it is clear that the Romans had not advanced beyond the earlier Greek conception, and were ignorant of the astronomico-mathematical method inaugurated by Hipparchus.

4. *Map-making in the Middle Ages.*—The scholastic Middle Ages confined themselves to imitation of the Roman *orbes*. Fulness of detail, moreover, was gradually lost, meagreness and crudity appearing in its place. Cartography in fact fell back to a second childhood. Fanatical exponents of the orthodox faith, like Lactantius, looked with disdain on all scientific culture. Geographical questions were of no interest to him because he regarded them as mere matters of opinion. Astronomy was a piece of fantastic folly, the knowledge of distant lands mere learned lumber. "Quæ beatitudo," he exclaims, "erit mihi proposita si sciero unde Nilus oriatur vel quicquid de cœlo physici delirant?" As this narrow conception of things became on the whole the dominant one, geography and map-making practically ceased to exist. The doctrine of the sphericity of the earth was placed under the ban of the church, and people went back to the Homeric idea of a disk surrounded by the ocean. Isidore of Seville (*ob.* 636) taught: "Orbis a rotunditate circuli dictus quia sicut rota est. Undique enim Oceanus circumfluens ejus in circulo ambit fines. Divisus est autem trifarie; e quibus una pars Asia, altera Europa, tertia Africa, quæ et Libya nuncupatur." Isidore is a master of false etymological inferences. Deriving *rotunditas* from *rota*, a wheel, he declares that consequently the earth has the appearance of a wheel. Hence the name wheel-maps has been given to all those maps of the earlier Middle Ages. The three-fold division which he gives of the world-disk kept its ground for centuries, and the figure of the earth put on the miserable guise shown in fig. 2. It was only by the Greek fathers that the doctrine of the earth's sphericity continued to be taught; and, as the knowledge of Greek rapidly died out in western Europe, the fountain was dried up from which a better science might have been derived. Many minor modifications were introduced into the map of the world, but the fundamental type remained as given in fig. 2. Jerusalem lay in the centre, Paradise in the extreme east. Clever artists gave life to the disk of the world by turreted pictures of towns—Jerusalem, Troy, Babylon, Rome, &c., and drew Adam and Eve in the midst of a Paradise which

was defended by a fence of thorns or of flames, and, being considered the highest place in the world, was always introduced at the top of the map! The positions of Jerusalem and Paradise served to fix the other points. How long this conception remained in vogue appears from

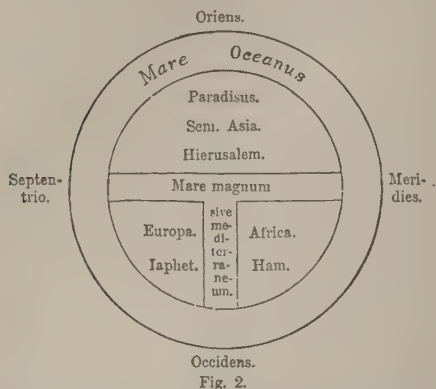


Fig. 2.

the fact that in 1422 Leonardo Dati, in a poem on the sphere (*Della Spera*), wrote, "A T within an O shows the design" (*Un T dentre a uno O mostra il disegno*), thus ⊖. In this way the whole science of cartography sank back below the level attained by the Ionian Greeks.

5. *Map-making among the Arabians.*—The first development of geographical science among the Arabs took place at Baghdad about 772 A.D., in the reign of the caliph Mansúr, and under the influence of an Indian astronomer and mathematician; and, not long after the works of Euclid, Archimedes, Aristotle, and Ptolemy were translated into Arabic, by orders of the caliph Mamún (813–833), a degree was measured in Mesopotamia in the plain of Sinjar, and a system of the world (Rasm el-arḍ) was constructed by his librarian Mohammed ben Musa of Khiva (Alcharesmius), in which every place was to be determined by longitude and latitude in the style of Ptolemy. But the science split up only too soon into a practical and a theoretical (astronomical) section—the one treating geography (ja'rafíyá) as the doctrine of routes and provinces, the other as the doctrine of latitudes and longitudes. Astronomy contented itself with the astronomical determination of the position of places without drawing maps or exerting any influence on their projection; travellers and topographers on the other hand did not trouble themselves about astronomy, but like Istakhri (*c.* 750) or Ibn Ḥaukal (*c.* 750) added maps to their descriptions which were destitute of any system of degrees, and betrayed by the roughness of their outlines the clumsiness of the draughtsman. Ultimately, like Dimishḳí (1327), they left mathematical geography completely out of their works, Ibn Ḥaukal having already declared that mathematical division only brought confusion into geography. Only Edrísí's map, engraved for King Roger II. of Sicily upon a silver plate (1164), forms an exception; but, as it was not drawn according to the Ptolemaic projection, but simply indicated the seven climates, it was after all but an unsuccessful copy of Ptolemy.

6. *Nautical Maps.*—The nautical (loxodromic or compass) maps, which make their first appearance in Italy in the 13th century, indicate a gratifying improvement in cartography after a long period of stagnation. These maps were constructed with the aid of the compass, and took the name of compass-maps because they are covered with the figure of a compass from which numerous straight lines radiate out in all directions over the sheet. The fact that the magnet turns towards the north is first mentioned in 1187. Flavio Gioja of Amalfi was perhaps the first to make a mariner's compass and to teach seamen the use of that important instrument. The Italians divided the compass into eight parts (venti), assigning 45° to each—Tramontane (N.), Greco (N.E.), Levante (E.), Sirocco (S.E.), Ostro (S.), Libeccio or Garbino (S.W.), Ponente (W.), Maestro (N.W.). Every division had four quarters (quarte di vento), each of 11¼ degrees. The maps were produced as follows. The courses of individual ships were first of all inserted as straight lines, calculated according to the distances traversed, from particular ports, as Genoa or Venice, to other ports, and when a good supply of such material had been collected and a series of diagonals drawn in accordance therewith, the most important points on the coast and in the islands were fixed. The lines by which the meridians were cut at the same angle were called loxodromes; they gave a correct indication when they cut the true astronomical meridian, a false one when they cut the magnetic meridian. On the Italian charts the loxodromes were drawn as straight lines. The numerous radii of the compass shown on the maps enabled the seaman to find the direction which he had to take to reach his goal. Hence the title loxodromic maps.

Charts on which the degrees were marked became necessary only when navigation extended to the ocean; they were introduced by the Portuguese, probably at the suggestion of Prince Henry the Navigator. They are "plane charts" with lines of longitude and latitude.

The oldest loxodromic charts which have been preserved come from Pisa, Genoa, and Venice. The earliest, the so-called Pisan chart, belongs probably to the middle of the 13th century, and already comprises the whole Mediterranean. As this representation of the whole must of necessity have been preceded by surveys of the several portions, the beginning of the chart may be placed at least as far back as the first part of the 13th century. Next in point of age comes (2) the Luxoro Atlas in Genoa about the year 1300, in the possession of the Cavaliere Tomas Luxoro. Then follow (3) Petrus Vesconte, 1311, in the national archives at Florence, including the eastern Mediterranean (*Petrus Vesconte de Janua fecit ista carta ann dñi M°CCCXI°*), see fig. 3; (4) Marino Sanudo, a map of the world representing the Mediterranean and the Atlantic coasts as far as Flanders, probably drawn between 1312 and 1321—several copies in Rome (the Vatican), Venice, and Brussels; (5) an atlas of Petrus Vesconte's about 1313 (in Venice, in eight sheets; in Milan, ten sheets); (6) Perrinus Vesconte, 1327, in the Laurentian Library at Florence; (7) Joannes da Carignano, between 1306 and 1333, in the archives of Florence (*Presbiter Joannes rector sancti Marci de portu Januæ me fecit*); (8) a map of 1346 in the Castilian tongue, in the National Library at Paris; (9) the Medicean atlas of 1351 in the Laurentian Library at Florence, eight sheets, which represents also the Caspian Sea, and, remarkable enough, the whole of Africa; (10) Pizigani, 1367, in the National Library at Parma, a map of the world which extends as far as Persia, with numerous entries not only on the coasts but also in the interior; (11) an atlas of Pizigani, of date 1363, nine sheets in folio, in the Ambrosian Library in Milan, comprising the Mediterranean and the Ocean as far as Jutland (*M.CCCLXXIII a die VIII di zugno franzescho piziganij veniziano in veniexia me fecit*); (12) the famous Catalonian map of the world of 1375, in four sheets, in the National Library at Paris; (13) a map by Guill. Solerio of Majorca, 1385, in the public archives in Florence; and (14) atlas by some unknown hand, four sheets folio, in the Biblioteca Marciana at Venice.

Several of these Italian maps give indubitable evidence that as early as the 14th century the Azores and Canaries had been discovered, as well as the coast of Africa as far as beyond Cape Bojador. With the middle of the century the coast maps developed into maps of countries with trade routes, pictorial figures, and numerous inscriptions. Maps preserved from the 15th century are still more numerous:—(15) a map by the Venetian Nicolao, of date 1408, in Vienna; (16) Mecia de Villa destes, 1413, in the National Gallery at Paris; (17) a map of the world of 1417, in the National Library at Florence; (18) Francesco de Cesanis, 1421, in the Museo Correr at Venice; (19) a map of 1424 at Weimar; (20) atlases by Giacomo de Giraldi, 1426–43, in Venice and Milan; (21) Gabriel de Valsecqua, 1434, from Majorca; (22) Francesco Beccario, three maps, in the British Museum; (23) two maps by Battista Beccario in Munich (1426) and Parma (1435); (24) Andrea Bianco, 1436, an atlas of ten sheets, where for the first time the mediæval circular maps are accompanied by the Ptolemaic maps, in the Biblioteca

Marciana at Venice; also a map of 1413, drawn at London, now in the Ambrosian Library at Milan (*Andrea Bianco venecian connito di galia me fexe a londra*, 1448); (25) an elliptical map of the world in the Pitti Palace at Florence, of Genoese origin, and of date 1447; (26) Hannibal de Madiis, 1449, in the Ambrosian Library; (27) a Catalonian map of the world, of 1450 (?), in the National Library at Florence; (28) Giovanni Leardo, two maps of the world, of date 1448 (in the museum at Vicenza) and 1452 (the property of Consul-general von Pilat at Venice); (29) Fra Mauro, a famous map of the world from 1457–59 in the Biblioteca Marciana at Venice; (30) Gratioso Beninicasa of Ancona, a diligent cartographer, twenty-five very carefully executed works dating from between 1460 and 1482; most of them are in Italy, chiefly at Venice, two in Paris, one at Munich, and one without date in the British Museum; (31) Andrea Beninicasa, son of the preceding, three maps of 1476 (Geneva) and 1490 (Ancona and Rome); (32) Bartolomeo Pareto, a map of the world, of 1455, at Rome; (33) Giorgio Giovanni, 1484 (Parma); (34) Count Hortomanus Fredutins of Ancona, 1497 (Wolfenbüttel).

In the beginning of the 16th century, (35) Alberto Cantino, about 1501–3, was the first in Italy to draw a map representing portions of America, *Carta da navigare per le Isole nuovamente trovate in la parte delle Indie*, in the library at Modena. (36) The Maggiolo family, famous for its cartography, flourished in Genoa between 1511 and 1648. Visconte Maggiolo, the founder of the family, is known to have produced nineteen atlases between 1511 and 1587. A map by Giacomo Maggiolo, of date 1562, is in the British Museum. (37) Battista Agnese laboured between 1527 and 1554 in Venice, and the thirteen atlases he has left behind him are pieces of fine artistic work adorned with charming miniatures. Two of these atlases, of date 1527 and 1536, are in the British Museum.

In the 15th century and the beginning of the 16th Spanish, Portuguese, Greek, and French cartographers appear as competitors with the Italian, Catalonian, and Balearic artists. We name only the most important. Juan de la Casa, a Basque, and a companion of Columbus, drew in 1500 a map of the world in which for the first time the hitherto discovered coasts and islands of

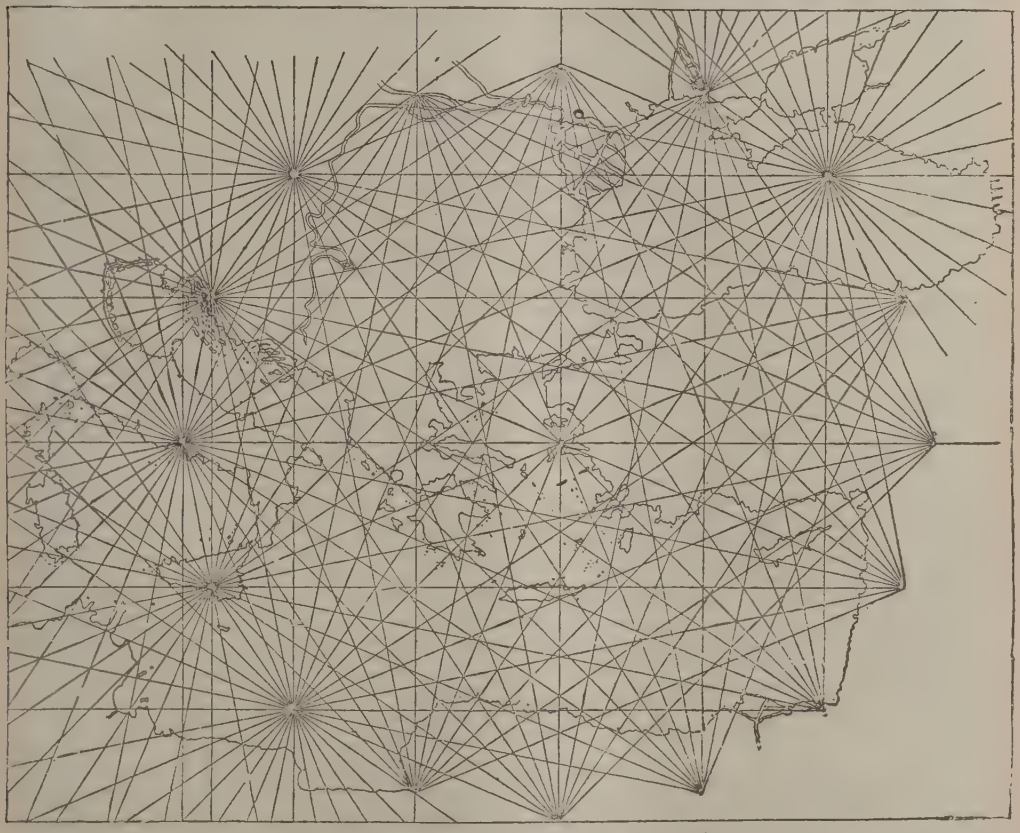

Fig. 3.—Chart of the Mediterranean (P. Vesconte, 1311).

America were introduced. A map of the world by Garcia de Torero, 1522, is preserved at Turin; and two general maps, the one dating 1527 (probably by Fernando Colon, son of Columbus) and the other 1529 (by Diego Ribero), exist at Weimar. Between 1558 and 1569 Diego Homem produced several beautiful atlases; of these four are in Italy, and one, of date 1568, at Dresden. Among the French world-maps a special place is due to that drawn up by order of King Henry II. It is published by Jomard in his *Monumens de la géographie*.

As far as Italian navigation extended, and especially within the limits of the Mediterranean, a very correct representation of the coasts and of the contours of the several countries was secured at an early date. The interior of the countries, on the other hand, remained confused and inexact. These defects were first supplied in the 15th century, when recourse was again had to the contributions of the Greeks, and especially of Ptolemy.

Before proceeding to discuss this new development, it may be as well to mention the various names by which the representations of the earth's surface have been designated. The Greeks employed the expression πίναξ (picture), the Romans in like manner said *tabula*. The word map came into use in the Middle Ages, the name *mappa-mundi*, *mappemonde* ("world-napkin"), proving that maps were originally painted on cloth. In English map is applied only to a land-map, the sea-map being known as a chart. The Romance languages had the expressions *disegno*, *figura*, *pintura*, *padron*. When the loxodromic maps came into existence, hand-books with sailing directions were written to accompany them, hence the titles "sailing directions," "sea-books," portulani (by which word actual maps were afterwards meant), or cartas da marear. The Latin word *charta* signifies originally a letter, a written document; and in like manner the Portuguese and Spanish form *carta*. But as early as the 14th century this expression was (as appears from the inscription quoted under No. 3 above) used to distinguish a sea-map. In the same sense Paolo Toscanelli speaks of his *carta*, which he sent to the king of Portugal. But the expression did not become general till the 16th century; in 1513 we find it in Germany in a Strasburg

edition of Ptolemy (Carta Marina Portugalensium), in 1524 in Spain (in the Junta of Badajoz), in 1582 in England (Michael Lock).

7. *The Revival of Ptolemy.*—This produced in the 15th century a revolution in the construction of maps, and laid the foundations of modern cartography. Ptolemy's great work again became generally well known in western Europe only after it was translated into Latin by Jacobus Angelus de Scarparia in 1409; and this version was first printed in 1475 at Vicenza without maps. The first edition with maps (to wit, a map of the world, ten maps of Europe, four of Africa, and twelve of Asia) appeared at Rome in 1478. Afterwards there were editions at Bologna (1482), Ulm (1482, by Nicolaus Donis with five modern maps), Ulm (1486), Rome (1490, 1507, and 1508, the last with seven modern maps, among which the famous map of the world by Joh. Ruysch), Strasburg (1513, with forty-seven maps); and in the course of the same century twenty-five other editions might be mentioned at Strasburg, Basel, Lyons, Cologne, Venice, and Paris. From this long series, which if prolonged to the beginning of the Thirty Years' War would be further increased by five, it is evident that Ptolemy was the great master of the modern time. At first maps were drawn according to Ptolemy's determinations of geographical position; but, in proportion as the study of mathematics, astronomy, and cosmography excited the interest of men of culture, opportunities were afforded of correcting Ptolemy's astronomical positions, especially in the case of central and northern Europe, where the range of the great cosmographer's knowledge had hardly enabled him to collect original material. The new arts of wood and copper engraving supplied the means for a rapid diffusion of *printed* maps. The oldest map printed from a wooden block (in the National Library at Paris), dating from 1460, and thus belonging to the earliest period of wood engraving, was produced in Germany, and represents Germany and western Europe. It is considered to be a copy from an old Roman map.

After the foundations of trigonometry had been laid by Purbach, Regiomontanus, and others, attempts of a rather rude kind were made in the beginning of the 16th century to execute geographical triangulations and delineations. The towns formed the central points of the system, their direction and position from the post of observation being fixed as precisely as possible, and their distance estimated in miles according to the best available data without being accurately measured. It was considered sufficient to assign in this way the relative positions of inhabited places, and the representation of the physical relations was very superficial; the course of rivers, for instance, was not measured, but carried past the towns on their banks in conventional lines.

In the Ptolemy of 1513 we already find three topographical maps, viz., one of Switzerland, one of the district of the upper Rhine from Basel to Mainz and Lorraine, and a large one of Crete, which it has been conjectured was taken from a Venetian original. The number of maps of smaller districts rapidly increased. In 1528 Aventinus drew the duchy of Bavaria, in 1533 Sebastian of Rotenhamm produced a map of East Franconia. Map drawing became a favourite occupation with the Germans. The best geographical survey of this period was the *Chorographia Bavariæ*, by the famous Philip Apianus (twenty-four sheets, at Ingolstadt, 1568). The number of cartographers increased so rapidly that Abraham Ortelius, in the first edition of his collection of maps (*Theatrum Mundi*, 1570), was able to give the names of ninety-three. The first attempts to improve and to increase the methods of projection known to the Greeks were made by Germans,—namely, Johann Stöffler (1452–1536), Johann Werner of Nuremberg (1468–1528), Peter Apianus (1495–1552). The last-mentioned introduced the favourite method of representing both hemispheres together in an elliptical form with lines of latitude. Maps of the world were compiled by Peter Apianus, Oronce Finé (1494–1555), Sebastian Cabot (1544), Giacomo Gastaldo (1546–48), Giov. Batt. Guicciardini (1549), Giov. Domin. Methoni at Venice, Heinrich Pontanus of Arnhem (1556, a map of the world in the shape of an imperial eagle), Guill. Postel at Paris (1581), &c.

8. *Mercator and his Successors.*—Gerhard Kramer, usually called Mercator (born of German parents at Rupelmonde in Flanders in 1512), has the honourable place of a reformer of cartography. We possess his map of Palestine (1537), a map of Flanders (Louvain, 1540) in nine sheets, phototyped in 1882, a globe (1541), and the first critical map of Europe (1554), by which he laid the foundation of his fame as the first cartographer of his age. The exclusive use of Latin letters for maps in Germany was due to his example. Especially famous is his map of the world (fig. 4) dating from 1569: "Nova et aucta orbis terræ descriptio ad usum navigantium emendate accommodata" (one copy in the National Library at Paris). This map is drawn in the projection of increasing latitudes with lines of latitude and parallel meridians, the basis of which was furnished by Edward Wright in 1599 in *Certain Errors in Navigation*. It is the first chart on which true rhumb lines could be drawn as straight lines. By 1601 Mercator's projection was in use for all sea charts. In 1578 Mercator drew up maps for Ptolemy exactly in accordance with his determinations; and these were followed by maps of Germany, the Low Countries, and France (1585), and of Italy (1590). It was his purpose to produce a complete collection of new maps, to which he gave the name *Atlas*; but he died in 1594, and the publication of this first atlas (1595) was left to his son. The title took the place of the designations previously in fashion—*Theatrum Orbis, Speculum Mundi*, &c. The second edition of the *Atlas* appeared in 1602. The later editions were issued by Jodocus Hondius in Amsterdam.

Before Mercator collections of maps, including various countries, and independent of Ptolemy, had begun to be published. Thus Christoffel Froschover in Zurich issued various "Landtafien" in 1562—a map of the world (Universalis Cosmographia, in the shape of a heart, dated MD.XL.VI.), Europe, Germania, Gallia, "die gantze Eydgnoschafft," and eight topographical maps of Swiss districts. Of much greater importance and influence was the collection published by Abraham Ortelius of Antwerp (1527–98), *Theatrum Orbis Terrarum* (1570), in which the best maps from all countries were re-engraved. The first edition with a Latin text contained fifty-three sheets; the seventh (1573) had sixty-nine maps, the twelfth (1579) ninety-two. Editions appeared with the text in German, French, Dutch, and after 1600 in English and Italian, and obtained the widest diffusion. Through this work the centre of cartographic activity was transferred to Holland. There too laboured the successors of Mercator,—Jodocus Hondius (1563–1611) and his son Henricus Hondius (1580–1644). Their maps, in several folio volumes, were numbered by hundreds. To the school of Mercator belonged also Petrus Plancius and Lucas Janszoon Waghenaer of Enkhuyzen (Aurigarius), who by his *Spieghel der Zeevaerdt* (Leyden, 1583) became the founder of nautical map-collections. In 1588 a reproduction of this atlas appeared in London as the first "Waggoner." In the beginning of the 17th century the town of Dieppe also produced excellent charts,—Guill Levasseur (1601), Jean Dupont (1625), and Jean Guerard (1631) being at work there. About the same time another famous cartographic family arose in Holland. William Jansz. Blaeu (1571–1638) and his sons Jan and Cornelis turned out about four hundred maps previous to 1655. William Blaeu was in 1633 appointed by public decree cartographer to the States-General; and it was his duty to examine the ships' logs and so amend the maps. He had a rival in the person of Jan Janszoon (Jansonius), who, working with the material inherited by him from his father-in-law Jodocus Hondius, produced a Dutch atlas in six volumes, a French in six folios, a German in nine folios, and a Latin in two. Cartography became a lucrative business, but the scientific value of the work grew less and less in the hands of Nicolaus Vischer (Piscator) from 1621 to 1670 and his son of the same name (*ob.* 1709), of Friedrich de Witt and his sons, and of Peter Schenck. The influence of the Dutch school, which had previously been so great, disappeared with the close of the 17th century.

In the 16th century the Italians were still active competitors with the Germans and Dutch. In engraved maps Venice held a specially high rank up to 1570, the Piedmontese Giacomo Gastaldo and Paolo Forlani of Verona being settled there. Their publications comprised well-nigh all parts of the earth. The progress of discovery can be followed on their general (*universale*) and topographical maps. Gastaldo's period of activity lay between 1546 and 1569, Forlani's between 1560 and 1570. They had a successor in Antonio

Magini (1555–1617) of Padua, who in his *Novæ geogr. tabulæ*, published in 1596, gave greater precision to the determinations of position. Giovanni Battista Nicolosi (1610–70) of Sicily issued at Rome a series of huge maps of the hemispheres and continents. Among the French map-makers of this period must be mentioned Oronce Finé (Finæus) from Dauphiné (1494–1555), who published in 1531 his *Planisphærium geographicum* in the shape of a heart according to the projection of Apianus; Jolivet (about 1560); Guillaume Postel (1505–81), who in 1570 drew a new map of France; the Franciscan André Thevet (1502–90), who in 1575 edited a *Cosmographie universelle* (2 vols. in folio), and finally Melchior Tavernier, a pupil of Ortelius (*ob.* 1641), who published many maps of European countries. In England there appeared in 1544 the great map of the world by Sebastian Cabot. The first modern map of England was produced by Humphrey Lhuyd in 1569 (*Angliæ regni tabula* and *Corographia Cambriæ*). He was succeeded by Christopher Saxton, who travelled through different parts of the country with several engineers, and in 1575 gave to the world his British atlas of thirty-six sheets, which Philip Lea afterwards reduced to twelve sheets. John Speed's atlas (*Theatrum*) of Great Britain was published at Amsterdam in 1610 by Jodocus Hondius. The first map of Scandinavia (*Regnorum Aquiloniorum Descriptio*) was produced in 1539 by Olaus Magnus, archbishop of Upsala. Much more accurate was the map drawn by Adrian Veno in 1613, and engraved by Jodocus Hondius, but the real reformer of northern cartography was Anders Buré (Læræus, 1571–1646), who surveyed the several parts of the country. His maps were afterwards published in the atlas of the brothers Blaeu between 1650 and 1660.

The first new map of Spain and the first of Portugal both appeared in the same year, 1560, the former being due to Pedro de Medina, the latter to Fernando Alvarez Secco.

During all this period there prevailed a remarkable variety in the determination of the first meridian. Whilst the Spaniards and Portuguese reckoned from the line of demarcation (370 leagues west of the Cape Verds) sanctioned by the pope, the Protestant Dutch, Germans, and English at first went back to Ptolemy, who began at the Canaries. Mercator, on his globe of the year 1541, chose the island Forteventura in the Canaries as his starting-point, but he afterwards adopted Corvo in the Azores, because he there approached the true indication of the magnetic needle. For the same reason Ortelius, the younger Mercator, Jansonius, and at first also William Blaeu fixed on the Isla del Fuego in the Cape Verd group. Blaeu afterwards proposed the Peak of Teneriffe, and in this he was followed by all Dutchmen. In the year 1634 Richelieu consulted

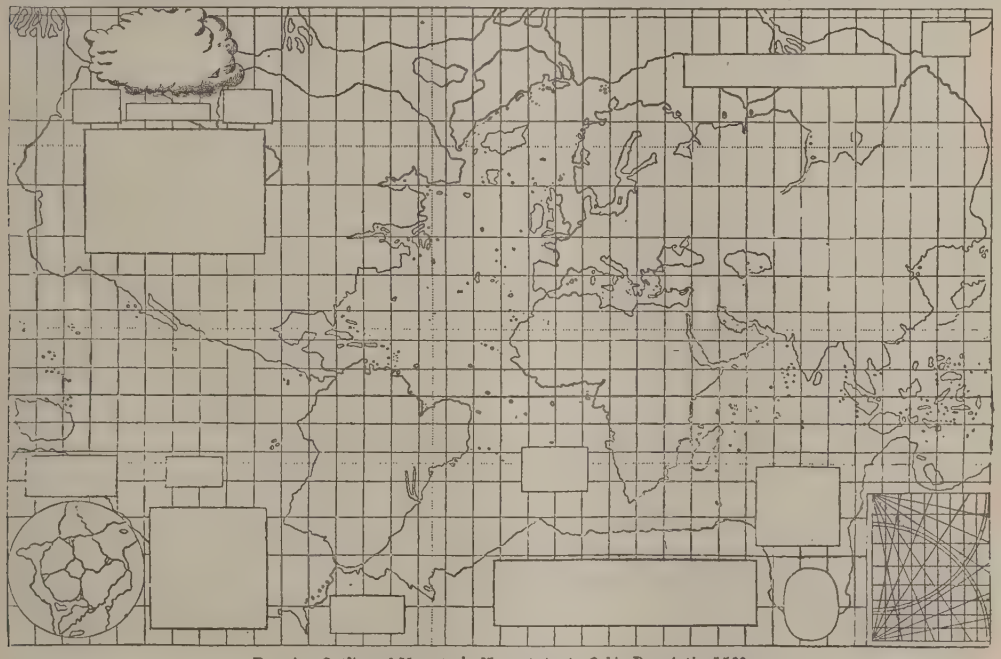

FIG. 4.—Outline of Mercator's *Nova et Aucta Orbis Descriptio*, 1569.

the astronomers Gassendi (1592–1655) and Morin (1583–1656), and in accordance with their decision Louis XIII. commanded, under penalty, that all French ships should calculate their longitudes from the meridian of Ferro, though it was not till the close of the 17th century that a French expedition determined with accuracy the relation of the position of Ferro to that of the observatory of Paris. It was in this way that the Ferro meridian obtained almost universal currency down to the 19th century. As in this period it was still practically impossible to secure precise determinations of longitude, all cartographic representations were naturally subject to considerable distortions, especially in countries outside of Europe.

9. *Period of Transition.*—A series of important discoveries and inventions in mathematics, physics, and astronomy having provided the means of making much more accurate observations and calculations, there followed as a matter of course a substantial improvement in cartography. Of chief moment were the invention of the telescope (1606), Galileo's discovery of Jupiter's moons (1610) and Cassini's calculation of their periods of rotation, so important for determinations of longitude (1666), the first application of trigonometry to geodesy by Snellius (1615), Picard's measurement of a degree between Paris and Amiens (1669 and 1670), the French measurement of a degree between Dunkirk and Perpignan by Cassini and Lahire (1683–1718), Hadley's mirror-sextant (1731; according to Newton's idea, 1699), the improvements made on the lunar tables by Tobias Mayer (1753), and John Harrison's chronometer (1761). In this way there set in a period of transition in cartography which lasted till somewhere about 1750; the results of new investigations and measurements were gradually turned to account, but, while here and there traditional blunders were corrected and expunged, nothing essentially new was as yet created.

To this epoch in Germany belong Johann Baptist Homann, (1664–1724), whose elegantly engraved maps, published in Nuremberg, continued to have a wide sale after his death, Johann Matthias Hase in Nuremberg (*ob.* 1743), and the famous Tobias Mayer (1723–86), who published in Nuremberg a critical map of Germany. In France eminence was obtained by Nicolas Sanson (1600–67) of Abbeville, who from 1627 worked at Paris as royal geographer, and issued more than three hundred maps; and the reputation of the house was maintained by his sons Nicolas, Adrien, and

Guill. Sanson, who worked along with Hubert Jaillot (1681–1717), Pierre du Val (1619–83), and Jean Baptiste Nolin (1692) at the French book of charts, *Neptune françois*, 1693, in which for the first time the new astronomical determinations were turned to account. Greater critical acumen was shown by the royal geographer Guill. de l'Isle (1675–1726), and especially by the talented Jean Baptiste Bourgignon d'Anville (1697–1782) and his younger contemporary Philippe Buache (1700–1773). In this period France was *facile princeps* in cartographic achievements, and led the way to the next and latest epoch. In England Dowet's *Atlas* was published at the cost of the duke of Argyll, and in the same year Aaron Arrowsmith was born (*ob.* 1828). A beginning of geodetic labour was at this time made in Sweden under Charles XI.,—the proceedings being carried on first under the Baron Karl Griepenhielm (*ob.* 1684) and afterwards under Count Dahlberg. For political reasons, however, the king did not allow the publication of the map of Sweden; but, the French ambassador D'Avaux having in 1704 got possession of copies, it was engraved at Paris by De l'Isle. In Italy P. Vincent Coronelli (*ob.* 1718) deserves to be mentioned.

10. *The Period of Triangulations and Geodetic Surveys.*—Up to this point the whole art of map-making had been treated as a matter of private speculation. It was France that gave the first example of carrying out the cartographic survey of the country at the cost of the state. Such surveys had a double object, one military, to provide the army with satisfactory maps, and the other administrative, to furnish a cadastre for the land tax. The military interest predominated; consequently the surveys have in almost all countries been carried out by officers of the general staff, and the maps are briefly designated as general staff or ordnance maps. For such a survey the whole country is covered with a network of triangles, and, in order to secure the most trustworthy basis for the representation, numerous points are astronomically fixed. In comparison with those of earlier date the maps thus produced are distinguished by correctness of detail. In the century between 1750 and 1850 attention was mainly directed to the accurate rendering of the horizontal development of the face of the country; but during the last thirty years the vertical configuration has also been faithfully represented on topographical maps of large scale by the introduction of contour lines. The first example of this also was given by France, when at Laplace's suggestion (1816) it was determined to publish a new map of France with curves of altitude. But owing to the great extent of the country, and the consequent difficulty and slowness of the undertaking, only four sheets of this kind were published by 1833. Hanover, however, followed suit in 1829, Baden in 1833, Hesse in 1840, and so on. Since the middle of last century nearly all the states of Europe have been active in map-making; and prolonged effort has produced rich results. Surveying and mapping have been followed by the publication of topographic maps. The states of the Balkan peninsula alone lag behind; there no comprehensive survey has been undertaken at public expense. As a summary of these great achievements in the larger part of Europe, we append a chronological[1] table of the most important surveys, with the date of the publication of the first sheet, the name of the country, the title of the map, the scale, and the number of sheets. Outside of Europe there are but few countries in which a survey based on exact triangulation has been carried out. The largest areas thus measured are the United States of North America and British India, where great activity has been shown; and to these may be added Asiatic Russia, portions of Australia, portions of the Dutch possessions in the East Indies, and Algeria. In the whole of South America there is only one country, Chili, of which we possess a map based upon a careful survey. In the second portion of the table consequently some maps are included which are merely the work of private cartographers, and the list must be regarded as tentative.

[1] For convenience of comparison the different series for the British Isles are grouped together in the table in the place of the earliest date.

*List of Topographic Maps.*

| Year. | Country. | Title of Map. | Scale. | No. of Sheets. |
|---|---|---|---|---|
| 1750 | France. | Carte géometrique de la France. | 1: 86,400 | 134 |

MAP, Mapes, or Mapus, Walter, an ecclesiastical statesman and renowned wit of the 12th century, must be ranked among the greatest of English writers, though French was the language that he used, and his personal fame has long been lost in the splendour of his creations. He was the cosmogonist and one of the principal creators of the Round Table legends, which supplied the ideal of chivalrous life to so many succeeding centuries. Most of the facts that are known about his position in the world have been gathered from a gossipy anecdotical work of his in Latin, *De Nugis Curialium*. He was probably a native of Herefordshire or Gloucestershire. He tells us that his parents rendered services to Henry II. both before and after his accession. He was acquainted with the household of Thomas Becket before this famous ecclesiastic became archbishop of Canterbury, which was in 1162. He studied in the university of Paris, attending the lectures of Girard la Pucelle, who began lecturing in 1160. Map seems to have risen rapidly in favour at the court of Henry II., combining ecclesiastical with civil and political functions. In 1173 he was an itinerant justice at the assize of Gloucester, and in the same year was with the court at Limoges, where the duty fell to him of entertaining the archbishop of Tarentaise, about whom he tells some marvellous stories. He was sent on a diplomatic mission to Louis le Jeune, king of France, and sat as a delegate in a council called by Pope Alexander III. (probably 1179), enjoying such repute that he was deputed to argue with the Waldenses. He accompanied Henry II. on all his progresses, and in return for his services received several ecclesiastical preferments. Apparently he maintained his position at court under Richard and John. In 1196 he was appointed archdeacon of Oxford, and in 1207–8 the custodes of the abbey of Eynsham were ordered to pay him his accustomed rent of five marks per annum. In the 12th century the abuses of the church were assailed with great freedom and abundance of humorous wit in rhymed Latin verse, and a century or two later rubrics appear in the MSS. of these satirical poems ascribing them to Walter Map. "Golias Episcopus" is the nominal author and hero of a great many of these effusions; that is to say, they represent the sayings and doings of Golias, the revelation made to him, the confession made by him, his creed, his reasons for not marrying, and so forth. The fact that Map's friend Giraldus Cambrensis denounces Golias as a foul-mouthed scoffer is rather against Map's alleged authorship, and they have probably been attributed to him in consequence of his great reputation as a wit, and a tradition that he had such a hatred of the White Monks that he exempted them from his oath as king's deputy to render even justice to all men. If these coarse and witty poems were really Map's, they are a proof of astonishing versatility, for they offer as great a contrast as possible to the high imaginative qualities, gracious tenderness, pure and lofty idealism, of his contributions to the Round Table legends. This is not the place for an exposition of the origin of these legends, but the *Quest du Saint Graal* was undoubtedly written by Map, being assigned to him in the earliest MSS. M. Paulin Paris ascribes to him also, upon grounds which commend themselves as being at least highly probable, the *Saint Graal*, and the noble prologue and the concluding parts of *Lancelot du Lac*. The effect of these contributions to the cycle was to completely transform its character, making out of it a lofty spiritual allegory, and forcing the paganism of the earlier legends into the service of the morality of the church. With such consummate skill did Map insinuate his story of the Graal into the cycle that the separate legends of Lancelot, Gawain, Percival, and Tristan seem to grow out of it; the whole luxuriant and irregular growth acquires a unity from its connexion with this root and stem. This reorganizing achievement alone, apart from the high romantic value of Map's independent additions, entitles him to a high place in literature.

The *De Nugis Curialium* and the Latin poems commonly attributed to Walter Mapes were edited by Mr Thomas Wright for the Camden Society; and the *Quest du Saint Graal*, by Mr Furnivall, for the Roxburghe Club.

MAPLE. Maples and the sycamore are species of *Acer*, suborder *Acerineæ*, order *Sapindaceæ*. The genus includes about fifty species, natives of Europe, North America, North Asia, especially the Himalayas and Japan (Benth. and Hook., *Gen. Pl.*, i. 409). Maples are for the most part trees with palmately-lobed leaves. The flowers are in corymbs or racemes,—the lowermost mostly male, the terminal bisexual. The fruit is a two-winged "samara."

The earliest known maples occur in the Miocene strata of Oeningen, where nineteen species have been discovered,—a greater number than occurs in any one district at the present day (Lyell's *El. of Geol.*, 6th ed. p. 250). A typical species appears to have been *Acer trilobatum*, Heer (*Flora Tert. Helv.*, pl. 114). This had many marked varieties, of which leaves, flowers, and fruit have all been discovered. The foliage was even attacked by a fungus, *Rhytisma induratum*, Heer, just as the sycamore is now by *R. acerinum*, which forms black spots on the leaves.

The common maple, *A. campestre*, L., is the only species indigenous to Great Britain. This and the sycamore were described by Gerard in 1597 (*Herball*, p. 1299), the latter being "a stranger to England." Many species have been introduced, especially from Japan, for ornamental purposes. The following are more especially worthy of notice.

*European Species.*—*Acer campestre*, L., the common maple, is common in hedgerows, but not often seen as a tree (see, however, Loudon, *Arboretum*, vol. i. p. 430). Loudon gives four varieties,—the downy-fruited, the variegated, the hill-inhabiting, and the

Austrian. It occurs in northern Europe, the Caucasus, and northern Asia. The wood is excellent fuel, and makes the best charcoal. It is compact, of a fine grain, sometimes beautifully veined, and takes a high polish. Hence it has been celebrated from antiquity for tables, &c. The wood of the roots is frequently knotted, and valuable for small objects of cabinet work. The young shoots, being flexible and tough, are employed in France as whips. *A. pseudo-Platanus*, L., the sycamore, or great maple, is a handsome tree of quick growth, with a smooth bark. The leaves are large, with finely acute and serrated lobes, affording abundant shade. Its longevity is from one hundred and forty to two hundred years. It is found in various parts of Europe in wooded mountainous situations. The wood when young is white, but old heart-wood is yellow or brownish. Like the common maple it is hard and takes a high polish. It is much prized by wheelwrights, cabinetmakers, sculptors, &c., on the Continent, while knotted roots are used for inlaying. Sugar has been obtained from the sap of this as from other species, the most being one ounce from a quart of sap. The latter has also been made into wine in the Highlands of Scotland. There are many varieties, the variegated and cut-leaved being the most noticeable (see *Gard. Chron.*, 1881, p. 229). For remarkable variations in the number of cotyledons arising from fusion, see a paper by the late Prof. J. S. Henslow in *Mag. Nat. Hist.*, vol. v. p. 346. *A. Platanoides*, L., the Norway maple (Loudon, *l.c.*, p. 408; *Gard. Chron.*, 1881, p. 564), is met with from Norway to Italy, Greece, central and south Russia. It was introduced into Britain in 1683. It is a lofty tree (from 40 to 70 feet), resembling the sycamore, but with yellow flowers, and more spreading wings to the fruit. There are several varieties. The wood is used for the same purposes as that of the sycamore. Sugar has been made from the sap in Norway and Sweden. The leaves of this species, in common with those of the sycamore especially, and perhaps all others, are liable to produce honeydew, which appears to be extravasated cell-sap. The present writer suggests that the starch formed in the leaves may be rapidly converted into sugar, which is then condensed on the surface of the leaf under excessive transpiration.

*Asiatic Species.*—Thirteen species are described by Hiern, chiefly in the temperate Himalayas (*Flor. of Brit. India*, p. 692; see also Brandis, *For. Fl.*, 110). The wood of some species is used, as that of *A. lævigatum*, Wall., for building; that of *A. cæsium*, Wall., being soft, inferior drinking cups are made of it; while that of *A. pictum*, Thunb., is white, light, and fine-grained.

*Japanese Species.*—Species, and many varieties, especially of *A. palmatum*, Thunb., generally known as *polymorphum*, with variously laciniated and more or less coloured foliage, have lately been introduced as ornamental shrubs. The original species was introduced in 1832. The branches and corolla are purple, the fruit woolly. The foliage of the typical form is bright green with very pointed lobes. It occurs in the central mountains of Nippon and near Nagasaki. Beautiful varieties have been introduced under the names *A. P. ampelopsifolium*, *atropurpureum*, *dissectum*, &c. They are remarkable for the coppery purple tint that pervades the leaves and young growths of some of the varieties (for figs., see *Catalogue of Hardy Trees*, &c., by Messrs Veitch). Of other Japanese species, *A. rufinerve*, Sieb. and Zucc., with the habit of the sycamore, from Nippon; *A. distylum*, Sieb. and Zucc., bearing leaves without lobes; *A. diabolicum*, Bl., with large plane-like leaves, from Nippon; and *A. carpinifolium*, Sieb. and Zucc., with foliage resembling that of the hornbeams, are especially worthy of note.

*North American Species.*—*A. saccharinum*, L., the sugar, rock, or bird's-eye maple, was introduced in 1735. It sometimes attains to 70 or even over 100 feet, more commonly 50 to 60 feet. It is remarkable for the whiteness of the bark. The wood is white, but acquires a rosy tinge after exposure to light. The grain is fine and close, and when polished has a silky lustre. The timber is used instead of oak where the latter is scarce, and is employed for axle-trees and spokes, as well as for Windsor chairs, &c. It exhibits two accidental forms in the arrangement of the fibres, an undulated one like those of the curled maple (*A. rubrum*), and one of spots which gives the name bird's-eye to the wood of this species. Like the curled maple, it is used for inlaying mahogany. It is much prized for bedsteads, writing desks, shoe lasts, &c. The wood forms excellent fuel and charcoal, while the ashes are rich in alkaline principles, furnishing a large proportion of the potash exported from Boston and New York. Sugar is principally extracted from this species, the sap being boiled and the syrup when reduced to a proper consistence run into moulds to form cakes. Trees growing in low and moist situations afford the most sap but least sugar. A cold north-west wind, with frosty nights and sunny days in alternation, tends to incite the flow, which is more abundant during the day than the night. A thawing night is said to promote the flow, and it ceases during a south-west wind and at the approach of a storm; and so sensitive are the trees to aspect and climatic variations that the flow of sap on the south and east side has been noticed to be earlier than on the north and west side of the same tree. The average quantity of sap per tree is from 12 to 24 gallons in a season. For full details of the preparation, &c., see Loudon, *l.c.*, p. 413; and *Gard. Chron.* 1878, p. 137.

*A. rubrum*, L., the red-flowering or scarlet maple, is a middle-sized tree, and was introduced in 1656. It is the first tree to blossom in spring in North America. The wood, like that of other species, is applicable to many purposes, as for the seats of Windsor chairs, turnery, &c. The grain in very old trees is sometimes undulated, which suggested the name of curled maple, and gives beautiful effects of light and shade on polished surfaces. The most constant use of curled maple is for the stocks of fowling pieces and rifles, as it affords toughness and strength combined with lightness and elegance. The inner bark is dusky red. On boiling, it yields a purple colour which with sulphate of iron affords a black dye. The wood is inferior to that of the preceding species in strength and as fuel. Sugar was made from the sap by the French Canadians, but the production is only half as great as that from the sugar maple (Michaux). In Britain it is cultivated as an ornamental tree, as being conspicuous for its flowers in spring, and for its red fruit and foliage in autumn. *A. macrophyllum*, Pursch., furnishes material for hats, baskets, mats, &c., from its inner bark, and the sap gives sugar. *A. circinatum*, Pursch., of California, has a fine, white, tough wood, which takes a good polish.

For description of other species of North America, see *Gard. Chron.*, 1881, Index, *s.v.* "Acer"; Sargent's *Cat. of For. Trees of N. Amer.*; Loudon, *l.c.*, p. 405 *sq.*; Gray's *Manual of Bot.*, p. 84. (G. H.)

MAR, EARLDOM OF. Mar, one of the ancient divisions or provinces of Scotland, comprised the larger portion of Aberdeenshire, extending from north of the Don southwards to the Mounth. It is remarkable for its association with the oldest historical dignity of Scotland, or perhaps of any country, which has been perpetuated to our own time. Donald MacEnun MacCainech, mormaer (hereditary ruler or steward) of Mar, fought, according to nearly contemporary testimony, at the battle of Clontarf in Ireland in 1014. Under Anglo-Saxon influences mormaers or great stewards became earls; and Ruadri, mormaer of Mar, whose name appears in the Book of Deer, is designed "Rothri comes" in a charter of Alexander I. of 1114 or 1115. His representative in the latter part of the 12th century was Gratney, earl of Mar, who married Christian Bruce, sister of King Robert, a lady famed for her defence of the chief stronghold of the earldom, Kildrummy Castle, against David of Strathbogie, earl of Athole, then (1335) in alliance with the English. Their son, Earl Donald, in his youth a captive in England, was restored to his country after Bannockburn. On the landing of Edward Balliol in 1332, and death of Thomas Randolph, earl of Moray, he was invested with the regency, and the troops hastily assembled by him to meet the invader suffered a disastrous defeat at Dupplin, the earl of Mar being himself among the slain. Earl Thomas, the regent's son, dying without issue in 1377, his successor was his sister Margaret, countess of Douglas by marriage. From her the earldom of Mar passed to her daughter, Isabel Douglas, countess of Mar, whose second marriage forms a notable episode in Scottish history. Alexander Stewart, natural son of Alexander, earl of Buchan, and, according to common belief, the instigator of a murderous attack on that lady's first husband, stormed the widowed countess of Mar in Kildrummy Castle in 1404, compelled her to marry him, and extorted from her a charter which, had the king been prevailed on to confirm it, would have made over the earldom to him and his heirs, in exclusion of the heirs of his wife. But, weak as was the law north of the Mounth in the reign of Robert III., this outrage was too flagrant to be condoned. The indispensable confirmation was refused by the king; but a compromise was effected, by which Isabel voluntarily accepted Stewart as her husband, and, by a charter which Robert duly confirmed, gave him a right to the earldom for life, with remainder, however, to her own heirs. *Qua* earl of Mar, the quondam leader of freebooters became a supporter of law and order; and in 1411, when Donald, lord of the Isles, was leading his marauding host southwards, it was under Alexander, earl of Mar, that the lowland gentry and the burghers of Aberdeen mustered to oppose

his advances. The sanguinary battle of Harlaw arrested the progress of the highlanders, and left Mar master of the field.

Earl Alexander died in 1435, when the right to the earldom passed to Isabel's nearest heir, Robert Lord Erskine (descended from a daughter of Earl Gratney), who established his right by retour in 1438, and became earl of Mar. The crown, however, had seized on the valuable territories of the earldom, of which he could only obtain partial possession; and James II. and his advisers, after temporizing for a length of time, in 1457 reduced Earl Robert's retour by a collusive "service negutive," based on the plea that, either by the bastardy of Alexander or in virtue of a resignation by him to James I., the earldom had lapsed to the crown, two *ex facie* worthless pretexts, inasmuch as Alexander had only been a liferenter. The wrongful possession of the crown lasted more than a century, in the course of which time the earldom was twice temporarily in possession of younger members of the royal house, and portions of it were given away to favourites; while its lawful owners, the Erskines, continued loyally to serve the sovereigns who had usurped their inheritance.

At length, on 23d May 1565, Queen Mary, made aware of the wrongs inflicted by her predecessors, and "moved by conscience" to make the fullest reparation, granted to John Lord Erskine a charter restoring the earldom of which he and his ancestors had been unjustly deprived. The earl of Mar, thus replaced in his rights, was regent of Scotland during the last two years of his life; and his son, who succeeded him in 1572, and was treasurer to James VI., recovered by process of law those portions of his inheritance which had been alienated by the crown during the period of illegal possession. In the next two generations the attachment of the family to the Stewarts brought with it fines and impaired fortunes. John, earl of Mar, fourth in descent from the treasurer, headed the rebellion of 1715, and suffered attainder, but escaped abroad and survived till 1732. His daughter Lady Frances (who married an Erskine, the younger son of her uncle, Lord Grange) would, but for the attainder, have inherited his title; and what remained of the lands was preserved to her by arrangement with the commissioners of forfeited estates. In 1824 her son, John Francis Erskine of Mar, was, as "grandson and lineal heir" of the attainted earl, restored by Act of Parliament from the effects of the forfeiture.

At the death in 1866 of John Francis Miller Erskine, earl of Mar, grandson of the restored earl, there seemed no room for doubt that the earldom devolved, in accordance with the rule of succession which it had always followed, on his sister's son John Francis Erskine Goodeve, in preference to his cousin and heir male, the earl of Kellie. The latter, however, claimed, not indeed the ancient dignity, but a separate titular earldom, supposed to have been bestowed by Queen Mary, not by her charter above alluded to, but by a lost and till then unheard-of patent a few weeks later in date, and with a different remainder, namely, to heirs male of the body. The resolution of the committee of privileges of the House of Lords in 1875, finding Lord Kellie entitled to the earldom thus claimed by him, has caused great surprise; and Scotch lawyers generally, while disbelieving as a question of fact in this creation of 1565, seem also to hold in point of law that the resolution alluded to leaves untouched the right of the heir general to the ancient historical honour. The same view has been expressed by way of protest by a large number of the Scottish peers, and enforced by the late earl of Crawford in his ably written posthumous work *The Earldom of Mar in Sunshine and Shade.*

MARABOUT is a corruption of the Arabic *Morábit*, a Moslem name for a hermit or a devotee. Primarily the word is derived from *ribát*, a fortified frontier station. To such stations pious men betook them to win religious merit in war against the infidel; their leisure was spent in devotion, and the habits of the convent superseded those of the camp (see De Slane in *Jour. As.*, 1842, i. 168; Dozy, *Suppl.*, i. 502). Thus *ribát* came to mean a religious house or hospice (*záwiya*). The great sphere of the marabouts is North Africa. There it was that the community formed by King Yahya and the doctor Abdalla developed into the conquering empire of the Morábits, or, as Christian writers call them, the ALMORAVIDES (*q.v.*), and there still, among the Berbers, the marabouts enjoy extraordinary influence, being esteemed as living saints and mediators. They are liberally supported by alms, direct all popular assemblies, and have a decisive voice in intertribal quarrels and all matters of consequence. On their death their sanctity is transferred to their tombs, where chapels are erected and gifts and prayers offered. The prominent part which the marabouts took in the resistance offered to the French by the Algerian Moslems is well known; and they have been similarly active in recent politico-religious movements in Tunis and Tripoli.

MARACAIBO, a city and seaport of Venezuela, the capital of the state of Zulia (formerly Maracaibo), lies about 25 miles from the sea on the west bank of Lake Maracaibo, the suburbs presenting, with their cocoa-nut groves, a fine contrast to the background of barren-looking hills sloping up from the shore to a height of about 200 feet. The streets are laid out at right angles; the houses are poor structures of a crude concrete or rubble, strengthened by wooden beams; and even the public buildings—such as the churches, the government house, the courthouse, and the theatre—owe their pretentious appearance to plaster and paint. The water of the lake being brackish, and the sinking of Artesian wells as yet in the experimental stage, Maracaibo is dependent on the rains for its drinking water. The markets are well supplied with provisions (especially game), and the lower classes, with whom the plantain forms the staff of life, are able to subsist in a state of comparative idleness. The prosperity of the place is due to the fact that it forms the outlet for the produce of a wide region; and if the bar at the mouth of the lake, preventing the entrance of vessels drawing more than 10 or 11 feet, were removed Maracaibo would bid fair to become the chief mercantile centre of the north coast of South America. Coffee, not of prime quality, cocoa, and hides are the principal exports at present, $4,029,852 out of the $4,188,617 at which the whole exports were valued in 1880 being drawn from these items. Steamers ascend the Catatumbo as far as San Buenaventura and Villarnizar and the Escalente to Santa Cruz, thus tapping the border provinces of both Venezuela and Colombia. Bricks and tiles, leather and admirable saddlery, cocoa-nut oil, sugar, rum, and chocolate are manufactured in the town. Though the Jesuit College, which formerly made Maracaibo one of the few real seats of learning in this part of the world, no longer exists, means of education are fairly abundant (a national college, a nautical school, &c.); and, although they devote themselves mainly to political agitation, the upper classes are not without culture. Maracaibo was founded by Alonso Pacheco in 1571. The population, returned in 1873 as 21,954, is estimated at 30,000 in 1881.

See Engel, "Maracaibo," in *Zeit. d. Ges. Erdk.*, Berlin, 1870; and *U. S. Consular Reports*, 1882.

MARÁGHA, a town of Persia, province Azerbijan, 37° 20′ N., 46° 25′ E., 68 miles from Tabríz, 232 north-west of Tehrán, pleasantly situated in a long narrow valley opening towards Lake Urmiah, which lies 10 miles to the north-west. The town consists mostly of mud houses enclosed by a high dilapidated wall, and containing no conspicuous buildings except a large bazaar and fine public bath. Násir-ed-dín's observatory formerly stood on a hill to the west, where there are some old tombs covered with Cufic inscriptions. The surrounding gardens and planta-

tions are watered by canals from a small river crossed here by two good bridges built in 1809. At the village of Dash-Kesen, 6 miles from Deh Kurgán in this district, are the famous Marágha marble pits, occupying a space half a mile in circumference, and sunk to a depth of about 12 feet. Here a multitude of springs charged with carbonic acid gas bubble up in all directions, precipitating large quantities of carbonate of lime. The marble in the semi-crystallized formation of this deposit forms horizontal layers, which when cut in thin slabs are nearly transparent, and serve as windows in the Tabríz baths and elsewhere. Larger blocks are also used as pavements in bazaars and palaces, and the famous throne in the Díwán Khána at Tehrán is made of the same material. Marágha was formerly the capital of Húlakú, grandson of Jenghis Khán, and its fifteen-thousand inhabitants still belong mostly to the Mukadam Turki tribe.

MARANHÃO, or MARANHAM (Latinized as *Maragnanum*), in full form SAO LUIZ DE MARANHÃO, the chief town of the province of Maranhão in Brazil, is situated in 2° 30′ S. lat. and 44° 17′ W. long., on the west side of an island of the same name 28 miles long and 15 broad. Though built on so hilly a surface that carriages cannot be used, it is laid out with regularity, and has straight, wide, and clean-looking streets. The public institutions comprise a naval arsenal, a high court of appeal, a tribunal of commerce, a military hospital, several general hospitals, a theatre, a museum, a public library, and a botanic garden, as well as a cathedral and an episcopal palace, both built by the Jesuits. Maranhão has some commercial importance, exporting cotton, sugar, hides, &c., from a wide region of the interior, and receiving manufactured goods from Europe, and especially from England. Though somewhat difficult of access to large sailing vessels, the port affords good anchorage to all drawing less than 20 feet. Steamers ply to Rio de Janeiro and Pará, as well as up the rivers Itapicuru, Guajahu, and Pindare; and direct steam communication is maintained with Lisbon and Liverpool. The population of the island Maranhão was 34,023 in 1872, about 30,000 belonging to the city.

French colonists settled at St Luiz in 1612, but they were expelled by Jeronimo d'Albuquerque in 1614. The Dutch were in possession from 1641 to 1653. The bishopric was created in 1676. The city was captured in 1823 by Lord Cochrane, who was afterwards created marquis of Maranham.

MARAT, JEAN PAUL (1743–1793), a famous revolutionary leader, was the eldest child of Jean Paul Mara of Cagliari and Louise Cabrol of Geneva, and was born at Boudry, in the principality of Neuchâtel, on May 24, 1743. His father was a doctor of some learning, who had abandoned his country and his religion, and had married a Swiss Protestant. It was he that laid the basis of the young Jean Paul's scientific learning, and the son at the same time imbibed the doctrines of Rousseau. On his mother's death in 1759 he set out on his travels, and spent two years at Bordeaux in the study of medicine, whence he moved to Paris, where he made use of his knowledge of his two favourite sciences, optics and electricity, to subdue an obstinate disease of the eyes. After some years in Paris he went to Holland, the retreat of philosophers, where all the works of the Encyclopédists were printed for the French market, and then on to London, where he settled in Church Street, Soho, a fashionable district, and practised his profession. In 1773, at the age of thirty, he made his first appearance as an author with a *Philosophical Essay on Man, being an Attempt to Investigate the Principles and Laws of the Reciprocal Influence of the Soul on the Body*, of which only two volumes are extant, though at the end of the second volume he speaks of a third. The book shows a wonderful knowledge of English, French German, Italian, and Spanish philosophers, and directly attacks Helvetius, who had in his *L'Esprit* declared a knowledge of science unnecessary for a philosopher. Marat, as he now began to call himself, declares that physiology alone can solve the problems of the connexion between soul and body, and proposes the existence of a nervous fluid as the true solution. In 1774 he published a political work, *The Chains of Slavery*, which appeared without his name, and was intended to influence constituencies to return popular members, and reject the king's friends, with innumerable examples from classical and modern history of the ways in which kings enslaved their peoples. The book was too late to have any influence on the general election, and was got up in a style too costly for a wide circulation, but its author declared later that it procured him an honorary membership of the patriotic societies of Carlisle, Berwick, and Newcastle. He remained devoted to his profession, and in 1775 published in London a little *Essay on Gleets*, price 1s. 6d., of which no copy is to be found, and in Amsterdam a French translation of the first two volumes of his *Essay on Man*. In this year, 1775, he visited Edinburgh, and on the recommendation of certain Edinburgh physicians, was, on June 30, made an M.D. of St Andrews University. On his return to London he published an *Enquiry into the Nature, Cause, and Cure of a Singular Disease of the Eyes*, with a dedication to the Royal Society. In the same year there appeared the third volume of the French edition of the *Essay on Man*, which reached Ferney, and exasperated Voltaire, by its onslaught on Helvetius, into a sharp attack, that only made the young author more conspicuous. His fame as a clever doctor was now great, and on June 24, 1777, the Comte d'Artois, afterwards Charles X. of France, "owing to the report he had heard of the good and moral life, and of the knowledge and experience in the art of medicine, of J. P. Marat," made him by brevet physician to his guards, with 2000 livres a year and allowances.

Marat was soon in great request as a court doctor among the aristocracy; and even Brissot, in his *Mémoires*, admits his influence in the scientific world of Paris. The next years were much occupied with scientific work, especially the study of heat, light, and electricity, on which he presented memoirs to the Académie des Sciences, but the Academicians were horrified at his temerity in differing from Newton, and, though acknowledging his industry, would not receive him among them. His experiments greatly interested Benjamin Franklin, who used to visit him; and Goethe always regarded his rejection by the Academy as a glaring instance of scientific despotism. In 1780 he had published at Neuchâtel without his name a *Plan de Législation Criminelle*, founded on the humane principles established by Beccaria. In April 1786 he resigned his court appointment. The results of his leisure were in 1787 a new translation of Newton's *Optics*, and in 1788 his *Mémoires Académiques, ou Nouvelles Découvertes sur la Lumière*.

His scientific life was now over, his political life was to begin; in the notoriety of that political life his great scientific and philosophical knowledge was to be forgotten, the high position he had given up denied, and he himself to be scoffed at as an ignorant charlatan, who had sold quack medicines about the streets of Paris, and been glad to earn a few sous in the stables of the Comte d'Artois. In 1788 the notables had met, and advised the assembling of the states-general. The elections were the cause of a flood of pamphlets, of which one, *Offrande à la Patrie*, was by Marat, and, though now forgotten, dwelt on much the same points as the famous brochure of the Abbé Siéyès. When the states-general met, Marat's interest was as great

as ever, and in June 1789 he published a supplement to his *Offrande*, followed in July by *La Constitution*, in which he embodies his idea of a constitution for France, and in September by his *Tableau des Vices de la Constitution d'Angleterre*, which he presented to the assembly. The latter alone deserves remark. The assembly was at this time full of Anglomaniacs, who desired to establish in France a constitution exactly similar to that of England. Marat, who had lived in England, had seen that England was at this time being ruled by an oligarchy using the forms of liberty, which, while pretending to represent the country, was really being gradually mastered by the royal power. His heart was now all in politics; and, feeling that his energies needed a larger scope than occasional tracts afforded, he decided to start a paper. At first appeared a single number of the *Moniteur patriote*, followed on September 12 by the first number of the *Publiciste parisien*, which on September 16 took the title of *L'Ami du Peuple*, and was to absorb his future life.

The life of Marat now becomes part of the history of the French Revolution. From the beginning to the end he stood alone. He was never attached to any party; the tone of his mind was to suspect whoever was in power; and therefore no historian has tried to defend him, and all state the facts about him with a strong colouring. About his paper, the incarnation of himself, the first thing to be said is that the man always meant what he said; no poverty, no misery or persecution, could keep him quiet; he was perpetually crying—"nous sommes trahis."

Further, the suspicious tone of his mind extended to his paper, and he made it play the part of the lion's mouth at Venice: whoever suspected any one had only to denounce him to the *Ami du Peuple*, and the denounced was never let alone till he was proved innocent or guilty. He began by attacking the most powerful bodies in Paris,—the corps municipal, with Bailly at their head, and the court of the Châtelet,—and after a struggle found them too strong for him, and fled to London (January 1790). There he wrote his *Denonciation contre Necker*, and in May dared to return to Paris and continue the *Ami du Peuple*. He was embittered by persecution, and continued his vehement attacks against all in power—against Bailly, against La Fayette, and at last, after the day of the Champs du Mars, against the king himself. All this time he was hiding in cellars and sewers, where he was attacked by a horrible skin disease, tended only by the woman Simonne Evrard, who remained true to him. The end of the constituent assembly he heard of with joy, and with bright hopes (soon dashed by the behaviour of the legislative) for the future, when almost despairing in December 1791 he fled once more to London, where he wrote his *École du Citoyen*. In April 1792, summoned again by the Cordeliers, he returned to Paris, and published No. 627 of the *Ami*. The war was now the question, and Marat saw clearly enough that it was not sought for the sake of France, that it was to serve the purposes of the royalists and the Girondins, who thought of themselves alone. The early days of the war being unsuccessful, the proclamation of the duke of Brunswick excited all hearts; who could go to save France on the frontiers and leave Paris in the hands of his enemies? Marat, like Danton, foresaw the massacres of September. After the events of August 10th he took his seat at the commune, and demanded a tribunal to try the royalists in prison. No tribunal was formed, and the massacres in the prisons were the inevitable result. In the elections to the convention, Marat was elected seventh out of the twenty-four deputies for Paris, and for the first time took his seat in an assembly of the nation. At the declaration of the republic, he closed his *Ami du Peuple*, and commenced a new paper, the *Journal de la République Françoise*, which was to contain his sentiments as its predecessor had done, and to be always on the watch. In the assembly Marat had no party; he would always suspect and oppose the powerful, refuse power for himself. After the battle of Valmy, Dumouriez was the greatest man in France; he could almost have restored the monarchy, yet Marat did not fear to go uninvited to the tragedian Talma's, and there accuse Dumouriez in the presence of his friends of want of patriotism. His unpopularity in the assembly was extreme, yet he insisted on speaking on the question of the king's trial, declared it unfair to accuse Louis for anything anterior to his acceptance of the constitution, and, though implacable towards the king, as *the* one man who must die for the people's good, he would not allow Malesherbes, the king's counsel, to be attacked in his paper, and speaks of him as a "sage et respectable vieillard." The king dead, the months from January to May were spent in an unrelenting struggle between Marat and the Girondins. Marat despised the ruling party because they had suffered nothing for the republic, because they talked too much of their feelings and their antique virtue, because they had for their own purposes plunged the country into war; while the Girondins hated Marat as representative of that rough red republicanism which would not yield itself to a Roman republic, with themselves for tribunes, orators, and generals. The Girondins conquered at first in the convention, and ordered that Marat should be tried before the Tribunal Revolutionnaire. But their victory ruined them, for Marat was acquitted on April 24, and returned to the convention with the people at his back. Their fall was a veritable victory for Marat. But it was his last. The skin disease he had contracted in the subterranean haunts was rapidly closing his life; he could only ease his pain by sitting in a warm bath, where he wrote his journal, and accused the Girondins, who were trying to raise France against Paris. Sitting thus on the 13th July he heard in the evening a young woman begging to be admitted to see him, saying that she brought news from Caen, where the escaped Girondins were trying to rouse Normandy. He ordered her to be admitted, asked her the names of the deputies then at Caen, and, after writing their names, said, "They shall be soon guillotined," when the young girl, whose name was Charlotte Corday, stabbed him to the heart. Grand was the funeral given to the man who had suffered so much for the republic. Whatever his political ideas, two things shine clearly out of the mass of prejudice which has shrouded the name of Marat—that he was a man of great attainments and acknowledged position, who sacrificed fortune, health, life itself, to his convictions, and that he was no *bête feroce*, no factious demagogue, but a man, and a humane man too, who could not keep his head cool in stirring times, who was rendered suspicious by constant persecution, and who has been regarded as a personification of murder, because he published every thought in his mind, while others only vented their anger and displayed their suspicions in spoken words.

The only works of Marat not mentioned in the text are *Les aventures du Comte Potowski*, a poor novel, which must have been written in his early days, and which was discovered in MS. and published by Bibliophile Jacob; two brochures on a balloon accident, 1785; *Les Charlatans Modernes, ou Lettres sur le Charlatanisme académique*, 1791; *Le Junius Français, journal politique*, June 2 to June 24, 1790; translation of *Chains of Slavery*, with fifty pages on French history prefixed, year 1.

On Marat's life should be read *L'ami du peuple, Skizzen aus Marat's journalistichen Leben*, Hamburg, 1846; A. Bougeart, *Marat, l'ami du peuple*, 2 vols., 1864; G. Piazzoli, *Marat, l'amico del Popolo e la Rivoluzione*, Milan, 1874; A. Vermorel, *Œuvres de J. P. Marat, l'ami du peuple, recueillies et annotées*, 1869; F. Chevremont, *Marat, Index du Bibliophile*, &c., 1876; Id., *Placards de Marat*, 1877; and particularly his *Jean Paul Marat, esprit politique, accompagné de sa vie scientifique, politique, et privée*, 2 vols., 1881. (H. M. S.)

MARATHON was a plain on the north-east coast of Attica, containing four villages—Marathon, Probalinthos, Tricorythos, and Oinoe, which formed a tetrapolis. It was divided from the plain of Athens by Mount Pentelicus and the hilly district of Diacria, and was in the early period an autonomous state. After it became incorporated in the Attic state, it retained something of its original distinctive character. The worship of Apollo had its first home in Attica here, and it was carried hence to Athens when the tetrapolis was made part of the Athenian commonwealth. The district was one of the chief seats of the worship of Hercules, and boasted that it was the first place where he had been worshipped as a god. Hence legend localized here several events in the story of the Heraclidæ, and especially the self-sacrifice of Macaria, daughter of Hercules. The legend of Theseus was also known in the district; here the hero slew the Marathonian bull. The plain derived its fame chiefly from the battle in which the Athenians and Platæans under Miltiades defeated the Persians, 490 B.C. The one hundred and ninety-two Athenians that were slain were buried on the field of battle, contrary to the usual Attic custom, and a mound, which is still called Soro, was erected over them. Another tumulus covered the bodies of the slain Platæans and slaves, and a special monument was raised to Miltiades.

MARBLE is a term applied to any limestone which is sufficiently close in texture to admit of being polished. Many other ornamental stones—such as serpentine, alabaster, and even granite—are sometimes loosely designated as marbles, but by accurate writers the term is invariably restricted to those crystalline and compact varieties of carbonate of lime which, when polished, are applicable to purposes of decoration. The crystalline structure is typically shown in statuary marble. A fractured surface of this stone displays a multitude of sparkling facets, which are the rhombohedral cleavage-planes of the component grains. On placing a thin section of Carrara marble under the microscope, it is seen that each grain is an imperfect crystal, or crystalloid, of calc-spar, having an irregular boundary, and being itself made up of a number of crystalline plates twinned together (see fig. 5, article GEOLOGY, vol. x. p. 231). It is said that a somewhat similar polysynthetic structure may be artificially induced in calc-spar by means of pressure. As marble appears to be, in many cases, a metamorphic rock, it is probable that pressure and heat have been the principal natural agents concerned in the alteration of compact into crystalline limestones. It was shown many years ago by Sir James Hall that even an earthy limestone, like chalk, when strongly heated in a closed vessel, might assume a saccharoidal texture; and it is a fact familiar to the field-geologist that a crystalline structure is often locally developed in limestone where it happens to have been invaded by an eruptive rock. Prof. Geikie proposes to distinguish this kind of metamorphism by the term *marmarosis* (*Text-Book of Geology*, 1882).

Among statuary marbles the first place may be assigned to the famous Pentelic marble, the material in which Phidias, Praxiteles, and other Greek sculptors executed their principal works. The characteristics of this stone are well seen in the Elgin marbles, which were removed from the Parthenon at Athens, and are now in the British Museum. The marble was derived from the quarries of Mount Pentelicus in Attica. The neighbouring mountain of Hymettus likewise yielded marbles, but these were neither so pure in colour nor so fine in texture as those of Pentelicus. Parian marble, another stone much used by Greek sculptors and architects, was quarried in the isle of Paros, chiefly at Mount Marpessa. It is called by ancient writers *lychnites*, in allusion to the fact that the quarries were worked by the light of lamps. The Venus de' Medici is a notable example of work in this material. Carrara marble is better known than any of the Greek marbles, inasmuch as it constitutes the stone invariably employed by the best sculptors of the present day. This marble occurs abundantly in the Apuan Alps, an offshoot of the Apennines, and is largely worked in the neighbourhood of Carrara, Massa, and Serravezza. Stone from this district was employed in Rome for architectural purposes in the time of Augustus, but the finer varieties, adapted to the needs of the sculptor, were not discovered until some time later. It is in Carrara marble that the finest works of Michelangelo and of Canova are executed. The purest varieties of this stone are of snow-white colour and of fine saccharoidal texture. Silica is disseminated through some of the marble, becoming a source of annoyance to the workman; while occasionally it separates as beautifully pellucid crystals of quartz known as Carrara diamonds. The geological age of the marbles of the Apuan Alps has been a subject of much dispute, some geologists regarding them as metamorphosed Triassic or even Liassic rocks, while others are disposed to refer them to the Carboniferous system. Much of the common marble is of a bluish colour, and therefore unfit for statuary purposes; when streaked with blue and grey veins, the stone is known as *bardiglio*. Curiously enough, the common white marble of Tuscany comes to England as Sicilian marble—a name probably due to its having been formerly re-shipped from some port in Sicily.

Although crystalline marbles fit for statuary work are not found to any extent in Great Britain, the limestones of the Palæozoic formations yet yield a great variety of marbles well suited for architectural purposes. The Devonian rocks of South Devon are rich in handsome marbles, presenting great diversity of tint and pattern. Plymouth, Torquay, Ipplepen, Babbacombe, and Chudleigh may be named as the principal localities. Many of these limestones owe their beauty to the fossil corals which they contain, and are hence known as madrepore marbles.

Of far greater importance than the marbles of the Devonian system are those of Carboniferous age. It is from the Carboniferous or Mountain Limestone that British marbles are mainly derived. Marbles of this age are worked in Derbyshire and Yorkshire, in the neighbourhood of Bristol, in North Wales, in the Isle of Man, and in various parts of Ireland. One of the most beautiful of these stones is the encrinital marble, a material which owes its peculiarities to the presence of numerous encrinites, or stone-lilies. These fossils, when cut in various directions, give a characteristic pattern to the stone. The joints of the stems and arms are known from their shape as "wheel-stones," and the rock itself is sometimes called entrochal marble. The most beautiful varieties are those in which the calcareous fossils appear as white markings on a ground of grey limestone. On the Continent a black marble with small sections of crinoid stems is known as *petit granit*, while in Derbyshire a similar rock, crowded with fragments of minute encrinites, is termed bird's-eye marble.

Perhaps the most generally useful marbles yielded by the Carboniferous system are the black varieties, which are largely employed for chimney-pieces, vases, and other ornamental objects. The colour of most black limestone is due to the presence of bituminous matter, whence the mineralogical name anthraconite. Such limestone commonly emits a fetid odour when struck; and the colour, being of organic origin, is discharged on calcination. Black marbles, more or less dense in colour, are quarried in various parts of Ireland, especially at Kilkenny and near Galway; but the finest kind is obtained from near Ashford

in Derbyshire. From Ashford is also derived a very beautiful stone known as rosewood marble. This is a dense brown laminated limestone, displaying when polished a handsome pattern somewhat resembling the grain of rosewood; it occurs in very limited quantity, and is used chiefly for inlaid work.

With the rosewood marble may be compared the well-known landscape marble or Cotham stone, an argillaceous limestone with peculiar dendritic markings, due probably to the infiltration of water containing oxide of manganese. This limestone occurs in irregular masses near the base of the White Lias, or uppermost division of the Rhætic series. It is found principally in the neighbourhood of Bristol. The arborescent forms depicted in bluish-grey upon this landscape marble form a marked contrast to the angular markings of warm brown colour which are seen on slabs of ruin marble from Florence—a stone occasionally known also as landscape stone, or *pietra paesina*.

British limestones of Secondary and Tertiary age are not generally compact enough to be used as marbles, but some of the shelly beds are employed to a limited extent for decorative purposes. Ammonite marble is a dark brown limestone from the Lower Lias of Somersetshire, crowded with ammonites, principally *A. planicostata*. Under the name of Forest marble, geologists recognize a local division of the Lower Oolitic series, so named by W. Smith from Wychwood Forest in Oxfordshire, where shelly limestones occur; and these, though of little economic value, are capable of being used as rough marbles. But the most important marbles of the Secondary series are the shelly limestones of the Purbeck formation. Purbeck marble was a favourite material with mediæval architects, who used it freely for slender clustered columns and for sepulchral monuments. It consists of a mass of the shells of a fresh-water snail, *Paludina carinifera*, embedded in a blue or grey limestone, and is found in the Upper Purbeck beds of Swanage in Dorsetshire. Excellent examples of its use may be seen in Westminster Abbey and in the Temple Church, as well as in the cathedrals of Salisbury, Winchester, Worcester, and Lincoln. Sussex marble is a very similar stone, occurring in thin beds in the Weald clay, and consisting largely of the shells of *Paludina*, principally *P. sussexiensis* and *P. fluviorum*. The altar stones and the episcopal chair in Canterbury cathedral are of this material.

Mixtures of limestone and serpentine frequently form rocks which are sufficiently beautiful to be used as ornamental stones, and are generally classed as marbles. Such serpentinous limestones are included by petrologists under the term ophicalcite. The famous *verde antico* is a rock of this character. Mona marble is an ophicalcite from the metamorphic series of the Isle of Anglesey, while the "Irish green" of architects is a similar rock from Connemara in western Galway. It is notable that some of the "white marble" of Connemara has been found by Messrs King and Rowney to consist almost wholly of malacolite, a silicate of calcium and magnesium.

A beautiful marble has been worked to a limited extent in the island of Tiree, one of the Hebrides, but the quarry appears to be now exhausted. This Tiree marble is a limestone having a delicate carnelian colour diffused through it in irregular patches, and containing rounded crystalloids of sahlite, a green augitic mineral resembling malacolite in composition. When dissolved in acid the marble leaves a brick-red powder, which has been studied by Dr Heddle, who has also analysed the sahlite.

Many marbles which are prized for the variegated patterns they display owe these patterns to their formation in concentric zones,—such marbles being in fact stalagmitic deposits of carbonate of lime, and probably consisting in many cases of aragonite. One of the most beautiful stalagmitic rocks is the so-called onyx marble of Algeria. This stone was largely used in the buildings of Carthage and Rome, but the quarries which yielded it were not known to modern sculptors until 1849, when M. Delamonte rediscovered the marble near Oued-Abdallah. The stone is a beautifully translucent material, delicately clouded with yellow and brown, and is greatly prized by French workmen. Large deposits of a very fine onyx-like marble, similar to the Algerian stone, have been worked of late years at Técali, about 35 miles from the city of Mexico. Among other stalagmitic marbles, mention may be made of the well-known Gibraltar stone, which is often worked into models of cannon and other ornamental objects. This stalagmite is much deeper in colour and less translucent than the onyx marbles of Algeria and Mexico. A richly tinted stalagmitic stone worked in California is known as Californian marble. It is worth noting that the "alabaster" of the ancients was stalagmitic carbonate of lime, and that this stone is therefore called by mineralogists "Oriental alabaster" in order to distinguish it from our modern "alabaster," which is a sulphate, and not a carbonate, of lime.

The brown and yellow colours which stalagmitic marbles usually present are due to the presence of oxide of iron. This colouring matter gives special characters to certain stones, such as the *giallo antico*, or antique yellow marble of the Italian antiquaries. Siena marble is a reddish mottled stone obtained from the neighbourhood of Siena in Tuscany; and a somewhat similar stone is found in King's County, Ireland. True red marble is by no means common, but it does occur, of bright and uniform colour, though in very small quantity, in the Carboniferous limestone of Derbyshire and north-east Staffordshire. It may be noted that the red marble called *rosso antico* is often confounded with the *porfido rosso antico*, which is really a red porphyritic felstone.

Fire marble is the name given to a brown shelly limestone containing ammonites and other fossil shells, which present a brilliant display of iridescent colours, like those of precious opal. It occurs in rocks of Liassic age at the lead-mines of Bleiberg in Carinthia, and is worked into snuff-boxes and other small objects. By mineralogists it is often termed *lumachella*, an Italian name which may, however, be appropriately applied to any marble which contains small shells.

It would unnecessarily extend this article to enumerate the local names by which marble-workers in different countries distinguish the various stones which pass under their hands. The quarries of France, Belgium, and Italy, not to mention less important localities, yield a great diversity of marbles, and almost each stone bears a distinctive name, often of trivial meaning.

America possesses some valuable deposits of marble, which in the eastern States have been extensively worked. The crystalline limestones of western New England furnish an abundance of white and grey marble, while a beautiful material fit for statuary work has been quarried near Rutland in Vermont. A grey bird's-eye marble is obtained from central New York, and the greyish clouded limestones of Thomaston in Maine have been extensively quarried. Of the variegated and coloured marbles, perhaps the most beautiful are those from the northern part of Vermont, in the neighbourhood of Lake Champlain. A fine brecciated marble is found on the Maryland side of the Potomac, below Point of Rocks. Among the principal localities for black marble may be mentioned Shoreham in Vermont and Glen Falls in New York. In Canada the crystalline limestones of the Laurentian series yield beautiful marbles.

Turning to India, we find important quarries at Makrana in Rajputana—a locality which is said to have yielded the marble for the famous Taj Mahal at Agra. In the valley of the Nerbudda, near Jabalpur, there is a large development of marble. The white marble which is used for the delicately-pierced screens called *jalee* work is obtained from near Raialo, in Ulwar. See Ball's *Economic Geology of India*, 1882.

For descriptions of ancient marbles see F. Corsi's treatise *Delle Pietre antiche*; and for marbles in general consult Professor Hull's *Building and Ornamental Stones*, 1872. (F. W. R.*)

MARBLEHEAD, a town and port of entry of the United States, in Essex county, Massachusetts, situated on the coast, 17 miles by rail north-east of Boston, and 4 miles south-east of Salem, and communicates by two branch lines with the main line of the Eastern Railway. It is built on a rocky peninsula of about 3700 acres in extent, which juts out into Massachusetts Bay, and has a deep, roomy, and nearly land-locked harbour. The fisheries in which Marblehead was once largely engaged have declined; but shoemaking has become an important industry, and the town is rising into favour as a summer resort. Many of the houses date from the "colonial" period, and one of the churches was built in 1714, but in the summer of 1877 nearly the whole business part of the town was burnt to the ground. The population was 7703 in 1870, and 7467 in 1880.

Marblehead was incorporated in 1649. Of the original settlers, a considerable number were from the Channel Islands, and their peculiarities of speech continued for a long time to affect the local dialect. As at that period the second town of Massachusetts in wealth and size, Marblehead sent one thousand men to the War of Independence, and its privateers rendered excellent service; but its trading prosperity never recovered from the effects of the contest. Elbridge Gerry, vice-president of the United States in 1812, was born at Marblehead; and the town is the scene of the grim revenge celebrated, with considerable poetical licence, in Whittier's *Skipper Ireson's Ride*.

MARBURG, an ancient university town of Prussia, in the province of Hesse-Nassau and district of Cassel, is very picturesquely situated on the slope of a hill on the right bank of the Lahn, 50 miles to the north of Frankfort-on-the-Main, and about the same distance to the south-west of Cassel. On the opposite bank of the river, which is here spanned by two bridges, lie the suburb of Weidenhausen and the station of the Main-Weser Railway. The streets of the town proper are steep and narrow, and the general character of the architecture is quaint and mediæval. The hill on which the town lies is crowned by the extensive old schloss, a fine Gothic building, the most noteworthy parts of which are the rittersaal (see below), dating from 1277–1320, and the beautiful little chapel. This chateau was formerly the residence of the landgraves of Hesse, afterwards served as a prison, and is now the repository of the historically interesting and valuable archives of Hesse. The chief architectural ornament of Marburg is, however, the Elisabethenkirche, a veritable gem of the purest Early Gothic style, erected by the grand master of the Teutonic Order in 1235–83, to contain the tomb of St Elizabeth of Hungary. The remains of the saint were deposited in a rich silver-gilt sarcophagus, which is still extant, and were afterwards visited by myriads of pilgrims, until the Protestant zeal of Landgrave Philip the Generous caused him to remove the body to some unknown spot in the church. The church also contains the tombs of numerous Hessian landgraves and knights of the Teutonic Order. The Lutheran church is another good Gothic edifice, dating mainly from the 15th century. The town-house, built in 1512, and several fine houses in the Renaissance style, also deserve mention. The university of Marburg, founded by Philip the Generous in 1527, was the first university established without papal privileges, and speedily acquired a great reputation throughout Protestant Europe. It has a library of 140,000 volumes, and is admirably equipped with medical and other institutes, which form some of the finest modern buildings in the town. The number of students is now about seven hundred. Marburg also possesses a gymnasium, a "realschule," an agricultural school, a society of naturalists, a hospital, a poorhouse, and an extensive lunatic asylum. It is the seat of a district court, and of superintendents of the Lutheran and Reformed churches. Marburg pottery is renowned; and leather, iron wares, and surgical instruments are also manufactured there. The population in 1880 amounted to 11,225. The environs are very picturesque.

Marburg is first historically mentioned in a document of the beginning of the 13th century, and received its municipal charter from Landgrave Louis of Thuringia in 1227. On his death it became the residence of his wife, Elizabeth of Hungary, who built a hospital there and died in 1231, at the age of twenty-four, worn out with works of religion and charity. She was canonized soon after her death. By 1247 Marburg had already become the second town of Hesse, and in the 15th and 16th centuries it alternated with Cassel as the seat of the landgraves. In 1529 the famous conference between Luther and Zwingli on the subject of transubstantiation took place there in the rittersaal of the schloss. During the Thirty Years' and Seven Years' Wars Marburg suffered considerably from sieges and famine. In 1806, and again in 1810, it was the centre of an abortive rising against the French, in consequence of which the fortifications of the castle were destroyed.

Several monographs have been published on the conference and university of Marburg. A general account of the town, with references to the most important of these, is given in Bücking's *Wegweiser durch Marburg*, 1875.

MARBURG, the second town of the Austrian duchy of Styria, is very picturesquely situated on both banks of the river Drave, in a plain called the Pettauer-Feld, at the base of the well-wooded Bachergebirge. It is the seat of the bishop of Lavant, and of the judicial and administrative authorities of the district, and contains a gymnasium, a "realschule," an episcopal seminary, a normal school, a pomological school, a theatre, and three hospitals. The principal buildings are the cathedral, the tower of which commands a beautiful view, and the old castle. Its situation in the midst of a fertile vine-growing district, connected by the navigable Drave with Hungary, and by railway with Vienna, Trieste, the Tyrol, and Carinthia, makes it the centre of a considerable traffic in wine and grain. Its industrial products are leather, iron and tin wares, liqueurs, and sparkling wine, and it also contains several large cooperages. The extensive workshops of the South Austrian Railway are situated in the suburb of Magdalena, on the right bank of the Drave, and give employment to nearly three thousand hands. With the exception of a successful resistance to Matthias Corvinus in 1480–81, the history of the town presents no notable event. In 1880 Marburg contained 17,628 inhabitants, including a garrison of 1600 men. The environs abound in interesting and picturesque points.

See Puff's *Handbook to Marburg*, Gratz, 1847.

MARCANTONIO, or, to give him his full name, Marcantonio Raimondi, is celebrated as the chief Italian master of the art of engraving in the age of the Renaissance. The date of his birth is uncertain, nor is there any good authority for assigning it, as is commonly done, approximately to the year 1488. He was probably born some years at least earlier than this, inasmuch as he is mentioned by a contemporary writer, Achillini, as being an artist of repute in 1504. His earliest dated plate, illustrating the story of Pyramus and Thisbe, belongs to the following year, 1505. Marcantonio received his training in the workshop of the famous goldsmith and painter of Bologna, Francesco Raibolini, usually called Francia. "Having more aptitude in design," says Vasari, "than his master, and managing the graver with facility and grace, he made waist-buckles and

many other things in niello, such being then greatly in fashion, and made them most beautifully, as being in truth most excellent in that craft." The real fame, however, of Marcantonio was destined to be founded on his attainments, not in the goldsmith's art generally, but in that particular development of it which consists of engraving designs on metal plates for the purpose of reproduction by the printing press. This art was not new in Italy in the days of Marcantonio's apprenticeship. It had been practised, in a more or less elementary form, for not less than forty or fifty years in the workshops of both Tuscany and Lombardy. A school of engravers had formed itself at Florence under the inspiration, as it appears, chiefly of Sandro Botticelli; in Lombardy the prevailing influence upon the nascent art had been that of Andrea Mantegna. But hitherto neither the engravers of Florence nor those of the Lombard cities had produced anything comparable for richness of effect and technical accomplishment to the work done during the same period on the other side of the Alps. The aim of the Italian engravers had not hitherto been directed, like that of Schongauer or Dürer, towards securing such freedom and precision in the use of the burin as should impart to the impressions taken from their engraved plates both a striking decorative effect and a power of suggesting to the eye a complex variety of natural objects and surfaces in light and shade. The Italian masters had been satisfied with a much more primitive order of effects. They had been content to omit all accessories and details except the simplest. They had merely drawn with the needle, or dry-point, upon the copper, in just the same way as they were accustomed to draw on paper with the pen or silver point,—taking great pains to get the outlines true and pure, and indicating shadows only by means of straight lines rapidly drawn in, or very simple hatchings.

By the beginning of the 16th century, however, when Marcantonio began to work at engraving along with the other pupils of Francia, a desire for a more complicated kind of effects was already arising among the followers of the art in Italy. Both backgrounds and passages of foreground detail were often imitated, inartificially enough, from the works of the northern masters. Marcantonio himself was among the foremost in carrying out this movement. There exist about eighty engravings which can be referred to the first five or six years of his career (1505–11). Their subjects are very various, including many of pagan mythology, and some of obscure allegory, along with those of Christian devotion. The types of figures and drapery, and the general character of the compositions, bespeak for the most part the inspiration, and sometimes the direct authorship, of that artist as graceful as he was grave, Francia. But the influence of German example is very perceptible also in the work of the young Marcantonio, particularly in the landscape backgrounds, and in the endeavour shown by him to express form by means of light and shadow with greater freedom than had been hitherto the practice of the southern schools. In a few subjects also the figures themselves correspond to a coarse Teutonic, instead of to the refined Italian, ideal. But so far we find Marcantonio only indirectly leaning on the north for the sake of self-improvement. It must have been for the sake of commercial profit that he by and by produced a series of direct counterfeits of northern work. We allude to the celebrated facsimiles engraved by Marcantonio on copper from Albert Dürer's woodcuts. These facsimiles are sixty-nine in number, including seventeen of Dürer's *Life of the Virgin*, thirty-seven of his *Little Passion* on wood, and a number of single pieces. According to Vasari, Dürer's indignation over those counterfeits was the cause of his journey to Venice, where he is said to have lodged a complaint against Marcantonio, and induced the signoria to prohibit the counterfeiting of his monogram, at any rate, upon any future imitations of the kind. Vasari's account must certainly be mistaken, inasmuch as Dürer's journey to Venice took place in 1506, and neither of the two series of woodcuts imitated by Marcantonio was published until 1511. The greater part of the designs for the *Life of the Virgin* had, it is true, been made and engraved seven years earlier than the date of their publication; and it is to be remarked that, whereas Marcantonio's copies of the *Little Passion* leave out the monogram of Dürer, it is inserted in his copies of the *Life of the Virgin*; whence it would after all seem possible that he had seen and counterfeited a set of impressions of this series at the time when they were originally executed, and before their publication. But the real nature of the transaction, if transaction there was, which took place between Dürer and Marcantonio, we cannot now hope to recover. Enough that the Bolognese engraver evidently profited, both in money and in education of the hand, by his work in imitating in a finer material the energetic characters of these northern woodcuts. He was soon to come under a totally different influence, and to turn the experience he had gained to account in interpreting the work of a master of a quite other stamp. Up till the year 1510 Marcantonio had lived entirely at Bologna, with the exception, it would appear, of a visit or visits to Venice. Very soon afterwards he was attracted for good and all into the circle which surrounded Raphael at Rome. Where or when he had first made Raphael's acquaintance is uncertain. His passage to Rome by way of Florence has been supposed to be marked by an engraving, dated 1510, and known as the Climbers, *Les Grimpeurs* (Bartsch 487), in which he has reproduced a portion of the design of Michelangelo's cartoon of the Battle of Anghiari, and has added behind the figures a landscape imitated from the then young Dutch engraver Lucas of Leyden. The piece in which he is recorded to have first tried his hand after Raphael himself is the Lucretia (Bartsch 192). From that time until he disappears in the catastrophe of 1527, Marcantonio was almost exclusively engaged in reproducing, by means of engraving, the designs of Raphael or of his immediate pupils. Raphael, the story goes, was so delighted with the print of the Lucretia that he personally trained and helped Marcantonio afterwards, adding, as some think, a touch of his own here and there to the engraver's work. A printing establishment was set up under the charge of Raphael's colour grinder, Il Baviera, and the profits, in the early stage of the business, were shared between the engraver and the printer. The sale soon became very great; pupils gathered round about Marcantonio, of whom the two most distinguished were Marco Dente, known as Marco da Ravenna, and Agostino de' Musi, known as Agostino Veneziano; and he and they, during the last ten years of Raphael's life, and for several years following his death, gave forth a great profusion of engravings after the master's work,—not copying, in most instances, his finished paintings, but working up, with the addition of simple backgrounds and accessories, his first sketches and trials, which often give the composition in a different form from the finished work, and are all the more interesting on that account.

The best of these engravings produced in the workshop of Marcantonio—those, namely, done by his own hand, and especially those done during the first few years after he had attached himself to Raphael—justly count among the most prized and coveted examples of the art. In them he enters into the genius of his master, the genius of choice, of balance, of rhythmical purity and charm; he loses little of the chastened science and subtle grace of

Raphael's contours, or of the inspired and winning sentiment of his faces; while in the parts where he is left to himself—the rounding and shading, the background and landscape—he manages his burin with all the skill and freedom which he had gained by the imitation of northern models, but puts away the northern emphasis and redundance of detail. His work, however, does not long remain at the height marked by pieces like the Lucretia, the Dido, the Judgment of Paris, the Poetry, the Philosophy, or the first Massacre of the Innocents. Marcantonio's engravings after the works of Raphael's later years are cold, ostentatious, and soulless by comparison. Still more so, as is natural, were those which he and his pupils produced after the designs of the degenerate scholars of Raphael and Michelangelo, of a Giulio Romano, a Polidoro, or a Bandinelli. Marcantonio's association with Giulio Romano was the cause of his first great disaster in life. He engraved a series of obscene designs by that painter in illustration of the *Sonnetti lussuriosi* of Pietro Aretino, and thereby incurred the anger of Pope Clement VII., at whose order he was thrown into prison. Marcantonio's ruin was completed by the calamities attendant on the sack of Rome in 1527. He had to pay a heavy ransom in order to escape from the hands of the Spaniards, and fled from Rome, in the words of Vasari, "all but a beggar." It is said that he took refuge in Bologna; but he never again emerges from obscurity, and all we know with certainty is that in 1534 he was dead.

MARCASITE. Modern mineralogists, following Haidinger, have restricted this name to those forms of native bisulphide of iron which crystallize in the orthorhombic system, and are sometimes known as "prismatic iron-pyrites." By the older mineralogists the word was used with less definite meaning, being applied to all crystallized and radiated pyrites, whether rhombic or cubic. In the last century both minerals were extensively used as ornamental stones. The marcasites were generally of small size, faceted like rose diamonds, and brilliantly polished, in which form they were mounted in pins, brooches, shoe-buckles, watch-cases, and other ornamental objects. The lustre of the polished surface was so brilliant that the stone, although opaque, formed a rough substitute for diamond; and this lustre was not readily impaired by atmospheric influences. Much of the old marcasite jewellery is of so pale a colour as almost to resemble burnished steel; such kinds generally belong to the true modern marcasite, sometimes called "white pyrites"; while the specimens which possess a brassy yellow colour are mostly referable to the cubic species, which is distinctively termed pyrite. Some of the finest pyrites suitable for the jeweller is found in Elba and in Brazil; but the mineral enjoys a very wide geographical distribution, and is common in England, especially in Cornwall, where it is known to the miners as "mundic." By the ancient Peruvians the mineral was extensively used for amulets, while the larger pieces were polished as mirrors; hence marcasite is sometimes called *pierre des Incas*. The word marcasite, variously written *marchasite, marchesite, marquesite, &c.*, appears to have been introduced from Spain, and is supposed to be of Arabic origin. It is notable that the word was applied by early writers on chemistry to the metal now called bismuth.

MARCELLINUS, St, according to the Liberian catalogue, became bishop of Rome on June 30, 296; his predecessor was Caius or Gaius. Of his pontificate virtually nothing is known. In the *Concilia* of Mansi and Hardouin there is an account of a synod alleged to have been held in 303 at Sinuessa (between Rome and Capua), at which Marcellinus was accused by three of his priests and two of his deacons of having accompanied Diocletian into the temple of Vesta and Isis, and there burnt incense. The narrative goes on to say that ultimately he confessed his guilt in the presence of the three hundred assembled bishops, but that his condemnation was left to himself, for "prima sedes non judicatur a quoquam." It is further stated in the same account that he and many of the other bishops were put to death by Diocletian on August 23, 303. The story of the synod of Sinuessa was current at an early date, but was condemned by Augustine and Theodoret as a mere invention of the Donatists. Its fabulous character is maintained by Döllinger (*Papstfabeln*) and by Hefele (*Conciliengeschichte*), even against the weighty authority of the *Breviary*, where it constitutes a lesson in one of the nocturns for April 26, the commemoration day of Marcellinus. Marcellinus died, according to the Liberian catalogue, in 304, after a pontificate of eight years three months and twenty-five days; after a considerable interval he was succeeded by Marcellus, who has sometimes been identified with him.

MARCELLUS, Marcus Claudius, Roman warrior, was born about 268 B.C., and served first in Sicily against Hamilcar. In his first consulship (222) he was engaged in the war against the Insubres, and won the *spolia opima* by slaying their chief Viridomarus. In 216 he was to have gone as prætor to Sicily with a fleet, but was detained on the news of the defeat at Cannæ. He went to Canusium and took command of the fragments of the army. He tried without success to prevent Capua going over to Hannibal, but saved Nola. In 214 he was in Sicily as consul at the time of the revolt of Syracuse; he stormed Leontini and besieged Syracuse, but the engineering skill of Archimedes repelled his attacks and compelled him to content himself with a blockade. Himilco landed with a Carthaginian army, and Marcellus failed to prevent their occupying Agrigentum. Taking the opportunity of a feast of Artemis, Marcellus stormed Epipolæ; but the old town and the island remained untaken, as also the fort of Euryalus, which was, however, cut off and soon fell. Meanwhile pestilence raged among the Carthaginian army encamped outside. After several months, during which disorder reigned in the town, he gained a lodgment by the aid of a Spanish officer, and Syracuse was surrendered (212). Marcellus spared the lives of the Syracusans, but carried off their art treasures to Rome. Consul again in 210, he took Salapia by help of the Roman party there, and put to death the Numidian garrison. Proconsul in 209, he attacked Hannibal near Venusia, and after a desperate battle retired to that town; he was accused of bad generalship, and had to leave the army to defend himself in Rome. In his last consulship (208), while both consuls were reconnoitring near Venusia, they were unexpectedly attacked, and Marcellus was killed. His successes have probably been exaggerated, but he was a brave soldier, and the name often given to him, the "sword of Rome," was well deserved. Though plebeians, the Marcelli henceforth took a high position; they were hereditary patrons of Sicily.

MARCELLUS, M. Claudius, was curule ædile in 56 B.C. with P. Clodius. In 52 he spoke on behalf of Milo at his trial. In 51 he was consul with Ser. Sulpicius. During his consulship he proposed to remove Cæsar from his army from March 49. The decision was, however, delayed by Pompeius's irresolution till February 50, and then the tribune C. Curio insisted that Pompeius also should vacate his command; and the senate voted this by a large majority. But at last C. Marcellus, cousin of Marcus, and then consul, went to Pompeius with the two consuls elect, and offered him the command of the army against Cæsar. In January 49 M. Marcellus tried to put off declaring war till an army could be got ready; but when Pompeius left Italy Marcus and his brother Caius followed, while his cousin withdrew

to Liternum. After Pharsalus M. Marcellus retired to Mytilene. He long made no attempt to return, till in 46 the senate appealed to Cæsar. Marcellus accepted this favour reluctantly. Pressed by Cicero, he left Mytilene for Italy, but was murdered in May by Magius Cilo in the Piræus. Marcellus was a thorough aristocrat, but free from the violence which disgraced many of his party.

MARCELLUS, M. Claudius, son of C. Marcellus and Octavia, sister to Octavianus, was born about 43 B.C. Octavianus adopted him and made him pontifex and senator with prætorian rank. In 25 he married Julia, daughter of Octavianus, and was looked on as his future successor. Yet in a dangerous illness Augustus gave his signet to Agrippa. Differences arising, Agrippa was made proconsul of Syria to separate the rivals. In 23 Marcellus, while curule ædile, fell ill and died at Baiæ. Livia was suspected of having poisoned him to get the empire for her son Tiberius. Great hopes had been built on the youth, and he was celebrated by many writers, especially by Virgil, in a famous passage in *Æn.* vi.

MARCELLUS I., pope, succeeded Marcellinus, after a considerable interval, most probably in May 307; under Maxentius he was banished from Rome in 309 on account of the tumult caused by the severity of the penances he had imposed on Christians who had lapsed under the recent persecution. He died the same year, being succeeded by Eusebius.

MARCELLUS II., Marcellus Cervini, cardinal of Santa Croce, a native of the Mark of Ancona, was elected pope in the room of Julius III. on April 9, 1555, but his feeble constitution succumbed to the fatigues of the conclave, the exhausting ceremonies connected with his accession, and the anxieties arising from his high office, on the twenty-first day after his election. He had a high reputation for integrity, tact, and ability. His successor was Paul IV.

MARCH, the third month of our modern year, contains thirty-one days. As in the Roman year so in the English ecclesiastical calendar used till 1752 this was the first month, and the legal year commenced on the 25th of March. The Romans called this month *Martius*, from the god Mars; and it received the name *Hlyd Monath, i.e.*, loud or stormy month, from the Anglo-Saxons. In France March was also generally reckoned the first month of the year until 1564, when, by an edict of Charles IX., January was decreed to be thenceforth the first month. Scotland followed the example of France in 1599; but in England the change did not take place before 1752. There is an old saying, common to both England and Scotland, which represents March as borrowing three days from April; thus the last three days of March are called the "borrowing" or the "borrowed days." In the *Complaynt of Scotland* we find "the borial blastis of the thre borouing dais of Marche hed chaisset the fragrant flureise of evyrie fruit-tree far athourt the feildis." An ancient popular rhyme says:—

> "March borrowit from Averill
> Three days, and they were ill;"

and then there is another rhyme which graphically characterizes those three "ill" days in detail:—

> "The first, it sall be wind and weet,
> The next, it sall be snaw and sleet;
> The third, it sall be sic a freeze,
> Sall gar the birds stick to the trees."

There is an old proverb, "A bushel of March dust is worth a king's ransom." Dry weather in March is generally favourable to the production of grain on clay lands; and hence a "dusty March" portended a plenteous season; while, on the contrary, a "wet March" frequently proved destructive of both wheat and rye.

The principal fixed days now observed and noted in the course of this month are the following:—March 1st, St David; March 12th, St Gregory; March 17th, St Patrick; and March 25th, Lady Day, one of the established quarter-days in England.

MARCHE, a former province of central France, was bounded on the N. by Berri, on the N. E. by Bourbonnais, on the E. by Auvergne, on the S. by Limousin, and on the W. by Angoumois and Poitou, embracing the greater part of the modern department of Creuse, a considerable portion of Haute-Vienne, and fragments of Charente and Indre. It derived its name from the circumstance of its being the "mark" or boundary between Poitou and Berri; it is sometimes referred to as Marche Limousine. It is first mentioned in history as a separate fief about the middle of the 10th century, when the countship of Marche was committed by Duke William III. of Aquitania to Boso I., count of Limoges and Charroux.

MARCHENA, a town of Spain, in the province of Seville, lies in a sandy valley, not far from the Corbones, a tributary of the Guadalquivir, about 30 miles east-south-east from Seville. It is a station on the line by which Seville and Utrera are connected with Osuna and the Cordova-Malaga line. Formerly it was surrounded with walls and towers, of which some traces still remain. Among the principal buildings is the palace of the dukes of Arcos (descendants of Ponce de Leon), within the enclosure of which is an ancient Moorish building, now the church of Santa Maria de la Mota, with a tower of considerable architectural merit. The ancient parish church of San Juan, rebuilt in 1490, has five naves. At the eastern end of the town is a sulphur spring which is a place of considerable resort for the cure of cutaneous diseases. The manufactures of the place are unimportant; there is some trade in the wheat, barley, olives, oil, and wine produced in the neighbourhood. The population in 1877 was 13,768. Marchena (the *Castra Gemina* of Pliny?) was taken from the Moors by St Ferdinand in 1240, and was presented to Ponce de Leon by Ferdinand IV. in 1309.

MARCIAN (Marcianus), emperor of the East from 450 to 457, was born in a private station of life in Illyria or Thrace, about the year 391, and at an early age entered the army, where after a considerable term of obscurity he attracted the attention of Ardaburius and subsequently of Aspar, being made military secretary and a captain in the guards. He accompanied Aspar in the ill-fated expedition against Genseric, by whom he was taken prisoner, but soon released. In 450, having in the meantime become tribune and senator, he went through the form of marriage with Pulcheria, the sister and successor of Theodosius II., and was crowned on August 25. In 451 he assembled the œcumenical council of Chalcedon, at which the proceedings of the "robber-synod" of Ephesus were annulled, and the Eutychian heresy condemned, a service to orthodoxy which has greatly endeared his memory to the minds of Catholic historians. In 452 his generals Ardaburius and Maximin respectively gained victories of some importance over the Arabs near Damascus and over the Blemmyes who had invaded the Thebaid; and after the death of Attila (453) he set about the task of repopulating the extensive tracts which had been devastated by the Huns. He maintained the peace of his dominions during the troubles which convulsed the Western empire in 455; and in 456 his arms were free to repress disturbances in Lazica which had been fomented by the Armenians and Persians. He died in 457, and was succeeded by Leo I.

MARCION and the Marcionite Churches. In the period between 130 and 180 A.D. the varied and complicated Christian fellowships in the Roman empire crystallized into close and mutually exclusive societies:—churches with

fixed constitutions and creeds, schools with distinctive esoteric doctrines, associations for worship with peculiar mysteries, and ascetic sects with special rules of conduct. Of churchly organizations the most important, next to catholicism, was the Marcionite community. Like the catholic church, this body professed to comprehend everything belonging to Christianity. It admitted all believers without distinction of age, sex, rank, or culture. It was no mere school for the learned, disclosed no mysteries for the privileged, but sought to lay the foundation of the Christian community on the pure gospel, the authentic institutes of Christ. The pure gospel, however, Marcion found to be everywhere more or less corrupted and mutilated in the Christian circles of his time. His undertaking thus resolved itself into a reformation of Christendom. This reformation was to deliver Christendom from false Jewish doctrines by restoring the Pauline conception of the gospel,—Paul being, according to Marcion, the only apostle who had rightly understood the new message of salvation as delivered by Christ. In Marcion's own view, therefore, the founding of his church—to which he was first driven by opposition—amounts to a reformation of Christendom through a return to the gospel of Christ and to Paul; nothing was to be accepted beyond that. This of itself shows that it is a mistake to reckon Marcion among the Gnostics. A dualist, we shall see, he certainly was, but he was not a Gnostic. For he ascribed salvation, not to "knowledge" but to "faith"; he appealed openly to the whole Christian world; and he nowhere consciously added foreign elements to the revelation given through Christ. It is true that in many features his Christian system—if we may use the expression—resembles the so-called Gnostic systems; but the first duty of the historian is to point out what Marcion plainly aimed at; only in the second place have we to inquire how far the result corresponded with those purposes.

The doctrines of Marcion and the history of his churches from the 2d to the 7th century are known to us from the controversial works of the catholic fathers. From Justin downwards, almost every eminent church teacher takes some notice of Marcion, while very many write extensive treatises against him. The most important of those which have come down to us are the controversial pieces of Irenæus (in his great work against heretics), Tertullian (*Adv. Marc.*, i.–v.), Hippolytus, Pseudo-Origen Adamantius, Epiphanius, and the Armenian Esnik. From these works the contents of the Marcionite Gospel, and also the text of Paul's epistles in Marcion's recension, can be settled with tolerable accuracy. His opponents, moreover, have preserved some expressions of his, with extracts from his principal work; so that our knowledge of Marcion's views is in part derived from the best sources.

Marcion was a wealthy shipowner, belonging to Sinope in Pontus. He appears to have been a convert from paganism to Christianity, although it was asserted in later times that his father had been a bishop. That report is probably as untrustworthy as another, that he was excommunicated from the church for seducing a virgin. What we know for certain is that after the death of Hyginus (or *c.* 139 A.D.) he arrived, in the course of his travels, at Rome, and made a handsome donation of money to the local church. Even then, however, the leading features of his peculiar system must have been already thought out. At Rome he tried to gain acceptance for them in the college of presbyters and in the church; indeed he had previously made similar attempts in Asia Minor. But he now encountered such determined opposition from the majority of the congregation that he found it necessary to withdraw from the great church and establish in Rome a community of his own. This was about the year 144. The new society increased in the two following decades; and very soon numerous sister-churches were flourishing in the east and west of the empire. Marcion took up his residence permanently in Rome, but still undertook journeys for the propagation of his opinions. In Rome he became acquainted with the Syrian Gnostic Cerdo, whose speculations influenced the development of the Marcionite theology. Still Marcion seems never to have abandoned his design of gaining over the whole church to his gospel. The proof of this is found, partly in the fact that he tried to establish relations with Polycarp of Smyrna,—from whom, to be sure, he got a sharp rebuff,—partly in a legend to the effect that towards the end of his life he sought readmission to the church. Such, presumably, was the construction put in after times on his earnest endeavour to unite Christians on the footing of the "pure gospel." When he died is not known; but his death can scarcely have been much later than the year 165.

The distinctive teaching of Marcion originated in a comparison of the Old Testament with the gospel of Christ and the theology of the apostle Paul. Its motive was not cosmological or metaphysical, but religious and historical. In the gospel he found a God revealed who is goodness and love, and who desires faith and love from men. This God he could not discover in the Old Testament; on the contrary, he saw there the revelations of a just, stern, jealous, wrathful, and variable god, who requires from his servants blind obedience, fear and outward righteousness. Overpowered by the majesty and novelty of the Christian message of salvation, too conscientious to rest satisfied with the ordinary attempts at the solution of difficulties, while yet he was in no position to reach an historical insight into the relation of Christianity to the Old Testament and to Judaism—who indeed was so in those days?—he believed that he expressed Paul's view by the hypothesis of two Gods: the just God of the law (the God of the Jews, who is also the Creator of the world), and the good God, the Father of Jesus Christ. Paradoxes in the history of religion and revelation which Paul draws out, and which Marcion's contemporaries passed by as utterly incomprehensible, are here made the foundation of an ethico-dualistic conception of history and of religion. It may be said that in the 2d century only one Christian—Marcion—took the trouble to understand Paul; but it must be added that he misunderstood him. The profound reflexions of the apostle on the radical antithesis of law and gospel, works and faith, were not appreciated in the 2d century. Marcion alone perceived their decisive religious importance, and with them confronted the legalizing, and in this sense Judaizing, tendencies of his Christian contemporaries. But the Pauline ideas lost their truth under his treatment; for, when it is denied that the God of redemption is at the same time the almighty Lord of heaven and earth, the gospel is turned upside down.

The assumption of two gods necessarily led to cosmological speculations. Under the influence of Cerdo, Marcion carried out his ethical dualism in the sphere of cosmology; but the fact that his system is not free from contradictions is the best proof that all along religious knowledge, and not philosophical, had the chief value in his eyes. The main outlines of his teaching are as follows. Man is, in spirit, soul, and body, a creature of the just and wrathful god. This god created man from Hyle (matter),[1] and imposed on him a strict law. Since no one could keep this law, the whole human race fell under the curse, temporal and eternal, of the Demiurge. Then a higher God, hitherto unknown, and concealed even from the

[1] On the relation of matter to the Creator Marcion himself seems not to have speculated, though his followers may have done so.

Demiurge, took pity on the wretched, condemned race of men. He sent His Son (whom Marcion probably regarded as a manifestation of the supreme God Himself) down to this earth in order to redeem men. Clothed in a visionary body, in the likeness of a man of thirty years old, the Son made His appearance in the fifteenth year of Tiberius, and preached in the synagogue at Capernaum. But none of the Jewish people understood Him. Even the disciples whom He chose did not recognize His true nature, but mistook Him for the Messiah promised by the Demiurge through the prophets, who as warrior and king was to come and set up the Jewish empire. The Demiurge himself did not suspect who the stranger was; nevertheless he became angry with Him, and, although Jesus had punctually fulfilled his law, caused Him to be nailed to the cross. By that act, however, he pronounced his own doom. For the risen Christ appeared before him in His glory, and charged him with having acted contrary to his own law. To make amends for this crime, the Demiurge had now to deliver up to the good God the souls of those who were to be redeemed; they are, as it were, purchased from him by the death of Christ. Christ then proceeded to the underworld to deliver the spirits of the departed. It was not the Old Testament saints, however, but only sinners and malefactors who obeyed His summons. Then, to gain the living, Christ raised up Paul as His apostle. He alone understood the gospel, and recognized the difference between the just God and the good. Accordingly, he opposed the original apostles with their Judaistic doctrines, and founded small congregations of true Christians. But the preaching of the false Jewish Christians gained the upper hand; nay, they even falsified the evangelical oracles and the letters of Paul. Marcion himself was the next raised up by the good God, to proclaim once more the true gospel. This he did by setting aside the spurious gospels, purging the real Gospel (the Gospel of Luke) from supposed Judaizing interpolations, and restoring the true text of the Pauline epistles. He likewise composed a book, called the *Antitheses*, in which he proved the disparity of the two gods, from a comparison of the Old Testament with the evangelical writings.

On the basis of these writings Marcion proclaimed the true Christianity, and founded churches. He taught that all who put their trust in the good God, and His crucified Son, renounce their allegiance to the Demiurge, and approve themselves by good works of love, shall be saved. But he taught further—and here we trace the influence of the current Gnosticism on Marcion—that only the spirit of man is saved by the good God; the body, because material, perishes. Accordingly his ethics also were thoroughly dualistic. By the "works of the Demiurge," which the Christian is to flee, he meant the whole "service of the perishable." The Christian must shun everything sensual, and especially marriage, and free himself from the body by strict asceticism. The original ethical contrast of "good" and "just" is thus transformed into the cosmological contrast of "spirit" and "matter." The good God appears as the god of spirit, the Old Testament god as the god of matter. That is Gnosticism; but it is at the same time illogical. For, since, according to Marcion, the spirit of man is derived, not from the good, but from the just God, it is impossible to see why the spiritual should yet be more closely related to the good God, than the material. There is yet another direction in which the system ends with a contradiction. According to Marcion, the good God never judges, but everywhere manifests His goodness,—is, therefore, not to be feared, but simply to be loved, as a father. But here the question occurs, What becomes of the men who do not believe the gospel? Marcion answers, The good God does not judge them, but merely removes them from His presence. Then they fall under the power of the Demiurge, who—rewards them for their fidelity? No, says Marcion, but on the contrary—punishes them in his hell! The contradiction here is palpable; and at the same time the antithesis of "just" and "good" ultimately vanishes. For the Demiurge now appears as an inferior being, who in reality executes the purposes of the good God. It is plain that dualism here terminates in the idea of the sole supremacy of the good God.

It is not surprising, therefore, that even in the 2d century the disciples of Marcion diverged in several directions. Rigorous asceticism, the rejection of the Old Testament, and the recognition of the "new God" remained common to all Marcionites, who, moreover, like the catholics, lived together in close communities ruled by bishops and presbyters (although their constitution was originally very loose, and sought to avoid every appearance of "legality"). Some, however, accepted three first principles (the evil, the just, the good); others held by two, but regarded the Demiurge as the god of evil, *i.e.*, the devil; while a third party, like Apelles, the most distinguished of Marcion's pupils, saw in the Demiurge only an apostate angel of the good God,—thus returning to monotheism. The golden age of the Marcionite churches falls between the years 150 and 250. During that time they were really dangerous to the great church; for in fact they maintained certain genuine Christian ideas, which the catholic church had forgotten. From the beginning of the 4th century they began to die out in the West; or rather they fell a prey to Manichæism. In the East also many Marcionites went over to the Manichæans; but there they survived much longer. They can be traced down to the 7th century, and then they seem to vanish. But it was unquestionably from Marcionite impulses that the new sects of the Paulicians and Bogomiles arose; and in so far as the western Katharoi, and the antinomian and anticlerical sects of the 13th century are connected with these, they also may be included in the history of Marcionitism.

*Literature.*—Baur, *Die Gnosis*, 1835; Möller, *Geschichte der Kosmologie in der griechischen Kirche*, 1860; Lipsius, *Gnosticismus*, 1860; Harnack, *Zur Quellenkritik der Geschichte des Gnosticismus*, 1873, and in the *Zeitschrift f. hist. Theol.*, 1874; Harnack, *De Apellis gnosi monarchica*, 1874; Lipsius, *Quellen der ältesten Ketzergeschichte*, 1875; Mansel, *The Gnostic Heresies*, 1875; Harnack, *Zur Geschichte der Marcionitischen Kirchen* (Hilgenfeld's *Zeitschrift*, 1876). Of the numerous works on Marcion's Gospel and Apostolos lists will be found in any introduction to the New Testament or history of the canon. The following are the ascertained results of criticism:—(1) Marcion was the first to make a canonical collection of New Testament writings; (2) his Gospel is to be regarded as a reconstruction, and not as the basis, of our canonical Gospel of Luke. (A. HA.)

MARCO POLO. See Polo.

MARCUS, the successor of Pope Sylvester I., according to the Liberian catalogue, had a pontificate of eight months and twenty days, from January 18 to October 7, 336. Of his character or history nothing is recorded. He was succeeded by Julius I.

MÁRDÍN, a town of Turkish Kurdistan, the seat of a governor dependent on the pasha of Diarbekir, is situated in 37° 20′ N. lat. and 41° E. long., about 60 miles south-east of Diarbekir, at a height of 3900 feet above the sea. Climbing the southern side of a steep conical hill (of soft limestone) in such a way that the roofs of the lower tier of houses serve as a street for those immediately above, Márdín presents a very picturesque appearance; and on the summit of the hill, which affords an unusually wide view over the Mesopotamian plain, stand the ruins of the famous castle Kal'ah Shuhbá (Maride and Marde in Latin, and similarly in Syriac), which, at least from the time of the Romans, played an important part in the history of this region. The Arabian geographers characterize it as

impregnable; and, the approaches being extraordinarily steep, narrow, and well arranged for purposes of defence, it was able to offer a protracted resistance to the Mongolian conqueror Hulagu, and to the armies of Timur. The castle was for hundreds of years the residence of princes more or less independent. The town has not much commerce or industry, but the surrounding country is distinguished for its excellent water and general fertility, and more especially for its fruit trees and melons. As regards their capacity and the honesty of their dealings, the people of Márdín do not enjoy the best reputation. They are estimated to number from 15,000 to 18,000; in 1870 Professor Socin was informed in the town that there were 600 Jacobite, 300 Catholic Armenian, 200 Catholic Syrian, 30 Chaldæan, and 57 Protestant families. Among the Jacobites are included a few remnants of the old sect called Shemsiye. See Ritter, *Erdkunde von Asien*, 2d ed., vol. vii.

MARGARET OF ANJOU, who became the queen of Henry VI. of England, was born at Pont à Mousson in Lorraine on the 24th[1] March 1429. Her father, "the good King René," as he was called in later years, did not at the time of her birth possess any of the pompous titles to which he afterwards laid claim, but was simply count of Guise, and younger brother of the existing duke of Anjou. He had, however, married Isabella, daughter of Charles II., duke of Lorraine, and during Margaret's infant years he succeeded to two dukedoms, first Lorraine and then Anjou, and afterwards to the crowns of Naples, Sicily, and Jerusalem. Some of these acquisitions, however, were no more than empty titles. He had a competitor for the duchy of Lorraine against whom he was unsuccessful in war, and he was actually a prisoner in the hands of the duke of Burgundy when the death of Joan II. of Naples first made him nominally a king. He deputed his wife Isabella to go to Naples and take possession of his new kingdom for him, and she took with her while on this enterprise her second son Louis and her second daughter Margaret, then in her seventh year. René himself obtained his liberty after a time, and followed his wife to Naples, but, being defeated by a rival there also, he returned to France after more than four years' absence. Before revisiting Lorraine or Anjou, he spent some time in Provence, and there received a proposal for the marriage of Margaret, who had by this time nearly completed her fourteenth year, from Charles, count of Nevers. It was accepted, and the contract was actually signed; but the marriage was delayed on account of some disputes about the settlement, and next year it was set aside for the more splendid match offered by the king of England.

This was in 1444. The earl, afterwards duke, of Suffolk, had proposed the match to Henry VI. as a means of terminating the long war with France, and securing peace upon a solid basis. Henry fully entered into the scheme, and was content for so great an object, not only to accept a bride without a dowry, but to give up to King René the provinces of Anjou and Maine. A great embassy was sent over to France, with Suffolk himself at its head, to negotiate the matter, and some months later the marriage was celebrated by proxy at Tours, Suffolk acting as Henry's representative. In April of the following year, 1445, Margaret crossed the Channel, and was received by Henry on her landing at Porchester. A few days later, 22d April, they were married in Tichfield Abbey, or, as some other authorities say, at Southwick,[2] and on Sunday the 30th of May Margaret was crowned at Westminster. Suffolk was now high in favour at court, but the policy he had pursued of giving up territory for the sake of peace was not likely to be generally acceptable in itself, and the events of the next few years completed his unpopularity. War broke out again with France in 1449, and in the course of a single year the whole of Normandy was lost to the English. Suffolk was impeached by the Commons, and the king was persuaded that the best way to protect him was to order him to quit the country. But he was taken and murdered at sea, and for some time the country was in a state of fearful anarchy. Margaret's position was now one that required great tact and delicacy. The king's marriage was already unpopular, and the fact was soon manifest that his wife possessed far higher abilities and greater power of governing than himself. This, together with the king's occasional attacks of mental imbecility, was really the great source of her misfortunes. During Henry's intervals of sanity it was she who really governed, and unfortunately she gave her whole support to the duke of Somerset, whose mismanagement abroad had been the immediate cause of the loss of Normandy. The duke of York vainly endeavoured to procure Somerset's removal, but he was so protected by the court that the complaints of his accuser were utterly unheeded, except during the king's periods of total incapacity, when the lords made York protector. Civil war at last broke out, and Somerset fell at St Alban's in 1455. Party feeling was bitterly exasperated, and Margaret, as we learn from a contemporary French historian, actually instigated an attack on Sandwich by the French out of hatred to the duke of York. At length, in 1460, that nobleman openly challenged the crown as his right and obtained from parliament, with the consent of Henry himself, a settlement of the succession in his favour. But at this time Margaret was out of the way. The king had been taken prisoner the year before by the Yorkists at the battle of Northampton, and she had sought refuge in Wales and Scotland along with her only son Edward, prince of Wales, then seven years old, who was now disinherited. Margaret's friends took up her cause in the north of England, and the duke of York, going to meet them, fell at the battle of Wakefield, 30th December 1460. Margaret naturally endeavoured to improve her victory by marching on to London. But Edward, earl of March, the duke of York's son, defeated her adherents on the borders of Wales, while the earl of Warwick with the king in his custody left London to oppose her. The ill-disciplined troops that she brought with her from the north ravaged the country as they went, and made themselves generally detested. But they overthrew Warwick's forces at St Alban's (the second battle fought there in this war), and liberated the king. The earl of March, however, soon came up and entered London, where he was proclaimed king by the name of Edward IV., amid the shouts of the citizens, who had always been devoted to his father. Margaret then thought it advisable to withdraw into the north along with Henry and her son, and Edward and Warwick pursued them into Yorkshire, where the bloody battle of Towton (29th March 1461) utterly crushed for the time the hopes of the house of Lancaster. Henry and Margaret fled to Scotland, and surrendered Berwick to the Scots as the price of their assistance. Margaret and her son soon after entered England with a body of Scots, who besieged Carlisle, but they were driven back by Lord Montague. Then King Henry accompanied another invasion into the county of Durham which was equally unsuccessful. Next year (1462) Margaret sailed from Kirkcudbright to seek aid in France, and offered the surrender of Calais to Louis XI. if Louis enabled her husband to regain his kingdom. Louis gave her two

[1] Most authorities say the 23d, but according to the MS. *Heures* of René, cited in the *Nouvelle Biographie Générale*, the day was the 24th.

[2] Southwick, according to Fabyan, who is followed by Hall and later writers; but William Wyrcestre and the anonymous author of the *English Chronicle* edited by Davies for the Camden Society, who are both strictly contemporary, say Tichfield.

thousand men under the command of Pierre de Brézé, and with these she made a descent upon Northumberland and took Bamborough and some other castles, which, however, were soon after besieged by King Edward's forces, and after a while recovered. King Edward himself, on hearing of her landing, hastened into the north, on which Margaret took ship to sail for France, but meeting with a storm was driven to land at Berwick and lost all her treasure. On the total failure of this expedition the well-known story is told by a French writer of her wandering with her son in a forest where she was attacked by robbers, and appealing successfully to the loyalty of one of them to save the son of his king.

Soon after, in April 1463,[1] she sailed to Flanders and sought the aid of Philip of Burgundy, but he declined to do more than relieve her poverty, and she retired to a castle in Lorraine, which her father gave her to occupy. Here Sir John Fortescue, who accompanied her into exile, superintended the education of her son, and composed for his benefit his celebrated treatise on the laws of England. Here also she apparently remained while her husband made further efforts and met with further defeats,—while he lay concealed, for more than a year, in Lancashire, was taken prisoner, and committed to the Tower. But in 1470, when her old enemy the earl of Warwick, having rebelled against King Edward, sought a refuge in France, Louis XI. induced her, though with great difficulty, to pardon him and concert measures along with him for her husband's restoration to the throne. The negotiation was cemented by an agreement for the marriage of her son, the prince of Wales, to the earl's daughter after the kingdom should be recovered, and so successful was the project that Edward was actually driven into exile, and for a period of six months Henry was again acknowledged as king. But the return of King Edward and the battle of Barnet once more changed the aspect of affairs before Margaret was able to rejoin her husband, and when she at length landed again in England she was defeated and taken prisoner at Tewkesbury. To add to her misery her only son Prince Edward was butchered after the battle. Four years later, in 1475, on peace being made between England and France, she was ransomed by Louis XI., and returned to her native country. She died at Dampierre near Saumur in Anjou, on the 25th of August 1482.

Dupont; Lord Clermont's edition of the *Works* of Sir John Fortescue. Mrs Hookham's *Life and Times of Margaret of Anjou* (London, 8vo, 1872) is an elaborate and useful work, but not always accurate and discriminating in the use of authorities.

MARGARET OF AUSTRIA (1480–1530), duchess of Savoy, and regent of the Netherlands from 1507 to 1530, was the daughter of the emperor Maximilian and Mary of Burgundy, and was born at Brussels on January 10, 1480. In 1482 she was betrothed to Charles, the son of Louis XI. (afterwards Charles VIII. of France); and in 1497 she was actually married to the infante John of Aragon, who left her a widow a few months afterwards. In 1501 she became the wife of Philibert II. of Savoy, who only survived until 1504; and in 1507 she was entrusted by Maximilian with the regency of the Netherlands and also with the charge of his grandson Charles. She died at Mechlin in 1530.

MARGARET OF AUSTRIA (1522–1586), duchess of Parma, and regent of the Netherlands from 1559 to 1567, was a natural daughter of Charles V. by Margaret van Gheenst, a Flemish lady, and was born at Brussels in 1522. In 1533 she was married to Alexander, duke of Florence; and, having been left a widow in 1537, she became the wife of Ottavio Farnese, duke of Parma, in 1542. The union proved an unhappy one, and she for the first time found a sphere for her somewhat masculine abilities in the Netherlands, which were entrusted to her care by her brother Philip II. of Spain on his departure for the peninsula in 1559 (see HOLLAND, vol. xii. pp. 74, 75). It was with much reluctance that she resigned the reins of power into the hands of the duke of Alva in 1567 and retired to Italy. Before her death, which occurred at Ortona in 1586, she had the satisfaction of seeing her son Alexander Farnese appointed to the government which she had occupied some twenty years before.

MARGARET, ST, queen of Scotland, born in Hungary about 1040, was a daughter of Edward the Atheling, son of Edmund Ironside; her mother was Agatha, most probably a niece of Queen Gisela of Hungary and of the emperor Henry II. She accompanied her father to England in 1057, and after the Norman Conquest she was brought (1068) to Scotland, where she became the wife of Malcolm Canmore in the spring of 1069. She survived her husband, who died in November 1093, by only a few days (see SCOTLAND). The chroniclers all agree in depicting Queen Margaret as a strong, pure, noble character, who had very great influence over her husband, and through him over Scottish history, especially in its ecclesiastical aspects. Her religion, which was genuine and intense, was of the newest Roman style; and to her are attributed a number of reforms by which the Church of Scotland was considerably modified from the insular and primitive type which down to her time it had exhibited. Among those expressly mentioned are a change in the manner of observing Lent, which thenceforward began as elsewhere on Ash Wednesday and not as previously on the following Monday, and the abolition of the old practice of observing Saturday (Sabbath), not Sunday, as the day of rest from labour (see Skene's *Celtic Scotland*, book ii. chap. 8). Her sons Edgar, Alexander, and David successively occupied the throne of Scotland; her elder daughter, Matilda, became the wife of Henry I. of England in 1101. Margaret was canonized by Innocent IV. in 1251, and by Clement X. she was made patroness of Scotland. Her festival (semi-duplex) is observed by the Roman Church on June 10.

MARGARET (1283–1290), known in Scottish history as the "Maid of Norway," was, through her mother Margaret, who had been married to Eric of Norway, the only grandchild of Alexander III. of Scotland, and was born in Norway in 1283. At the death of her grandfather (1286), while she was still an infant, Edward I. of England arranged for her betrothal to his son, but this policy was defeated by her early death, which took place, it was alleged, in Orkney, as she was on her way to Scotland, in 1290. The circumstances of her death were so obscure that doubts were entertained in some quarters whether she had not rather been spirited away. About 1300 a woman presented herself in Leipsic as the long-lost queen of Scotland; ultimately, however, she was burnt at Bergen as an impostor.

MARGARET OF VALOIS. See MARGUERITE.

MARGARITA, an island in the Caribbean Sea, about 8 miles off the coast of Venezuela, constituting along with the lesser islands Blanquilla and Hermanos the new state of Nueva Esparta. It has an area of 400 square miles,

[1] This is clearly the date intended by William Wyrcestre (p. 496); and it agrees entirely with Monstrelet (iii. 96). Yet almost all modern historians (except Lingard) and even biographers of Margaret of Anjou date her departure to Flanders after the battle of Hexham, at which she certainly was not present, as they would have her.

consists of two portions united by a low and narrow isthmus, is generally mountainous, and attains its greatest elevation of 4630 feet in Mont Macanao. The pearls from which Margarita takes its name, and which proved a considerable source of wealth in the 16th and 17th centuries, are no longer sought after; but the ordinary fisheries are actively prosecuted, and since the War of Independence, agriculture, trade, and industry have all greatly improved. Pompatar is the only harbour, Pueblo del Norte and Pueblo de la Mar being rather open roadsteads. Asuncion, the chief town, contains about 3000 inhabitants. The population of the island was 16,200 in 1807 (about 8000 being whites), and that of the state 30,983 in 1873.

Discovered by Columbus in 1498, Margarita was in 1524 bestowed by Charles V. on Marceto Villalobos. In 1561 it was ravaged by Lopez de Aguirre, a notorious freebooter, and in 1662 the town of Pompatar was destroyed by the Dutch. Long included in the government of Cumana, Margarita attained administrative independence only in the 18th century. In the War of Independence the inhabitants made an effective stand against Murillo; and to this they owe the honour of having their island erected into the state of New Sparta.

MARGARITA, St, virgin and martyr, is celebrated by the Church of Rome on July 20, but her feast formerly fell on the 13th, and her story is almost identical, even in the proper names, with that of the Greek St Marina (July 17). She was of Antioch (in the Greek story Antioch of Pisidia), daughter of a priest Ædesius. She lived in the country with a foster mother, scorned by her father for her Christian faith, and keeping sheep. Olybrius the "præses Orientis" sees her and offers his hand as the price of renunciation of Christianity. Her refusal leads to her being cruelly tortured, and after various miraculous incidents, in which a heavenly dove plays a prominent part, she is put to death. Women prayed to St Margarita for easy deliverance. It has been shown by H. Usener (*Legenden der heiligen Pelagia*, Bonn, 1879) that this legend belongs to a group of curious narratives which all have their root in a transformation of the Semitic Aphrodite into a Christian penitent or saint. Of these legends that of St Pelagia (*q.v.*) is perhaps the most important. Marina is a translation of Pelagia, and both are epithets of Aphrodite as she was worshipped on the coasts of the Levant. Pelagia in the legend has Margarito as her second name. The association of the marine goddess with the pearl is obvious, and the images of Aphrodite were decked with these jewels.

MARGATE, a municipal borough, market-town, and watering-place of Kent, England, is situated in the Isle of Thanet, 4 miles west of North Foreland, and by rail 90 miles east of London, with which it has also in summer daily steam communication by water. The streets of the town are regular and spacious, and there are many good villas in the suburbs. There is a marine terrace 2500 feet in length, parallel to which there is an esplanade. The pier, 900 feet long, was constructed by Rennie in 1810. A landing-place permitting the approach of vessels at all tides was constructed in 1854, and enlarged in 1876. The church of St John the Baptist, founded in 1050, contains some portions of Norman architecture, the remainder being Decorated and Late Perpendicular. It possesses several fine brasses and monuments. Among the other public buildings are the new town-hall, the market, the assembly rooms, the deaf and dumb asylum, and the royal sea-bathing infirmary, which has lately been much enlarged through the munificence of Sir Erasmus Wilson. The old name of Margate was *Meregate*, the entrance to the sea. Previous to the last century it was only a fishing village with a small coasting trade, but since then, owing principally to its fine stretch of sand, it has been steadily rising into favour as a watering-place, and is now one of the most favourite resorts of the middle classes of London. It received municipal privileges in 1857. The population of the municipal borough (384 acres) in 1871 was 11,995, and in 1881 it was 15,889.

MARGHILAN, Baber's Marghinan, 40° 28′ N. lat., 71° 45′ E. long., now the administrative centre of the Russian province of Ferghana (*q.v.*), a very old town, with high earthen walls and twelve gates, commanded by the fort of Yar Mazar, lies in a beautiful and extraordinarily fertile district of the same name, irrigated by canals from the Shahimardán river. The heat in summer is excessive. Population about 40,000, chiefly Usbeg. The principal industry is the production and manufacture of silk; camels' hair and woollen fabrics are also made. The new Russian town, planned by General Skobeleff, is 15 versts distant.

MARGUERITE de Valois. The name Marguerite was common in the Valois dynasty, and during the 16th century there were three princesses, all of whom figure in the political as well as in the literary history of the time, and who have been not unfrequently confounded. The first and last are the most important, but all deserve some account.

I. Marguerite d'Angoulême (1492–1549). This, the most celebrated of the Marguerites, bore no less than four surnames. By family she was entitled to the name of Marguerite de Valois; as the daughter of the Count d'Angoulême she is more properly and by careful writers almost invariably called Marguerite d'Angoulême. From her first husband she took during no small part of her life the appellation Marguerite d'Alençon, and from her second, Henri d'Albret, king of Navarre, that of Marguerite de Navarre. She was born at Angoulême on the 12th April 1492, and was two years older than her brother Francis I. She was betrothed early to Charles, Duke d'Alençon, and married him in 1509. She was not very fortunate in this first marriage, but her brother's accession to the throne made her, with their mother Louise of Savoy, the most powerful woman of the kingdom. She became a widow in 1525, and was sought in marriage by many persons of distinction, including, it is said, Charles V. and Henry VIII. In 1527 she married Henri d'Albret, titular king of Navarre, who was considerably younger than herself, and whose character was not faultless, but who seems on the whole, despite slander, to have both loved and valued his wife. Navarre was not reconquered for the couple as Francis had promised, but ample apanages were assigned to Marguerite, and at Nérac and Pau miniature courts were kept up, which yielded to none in Europe in the intellectual brilliancy of their frequenters. Marguerite was at once one of the chief patronesses of letters that France possessed, and the chief refuge and defender of advocates of the Reformed doctrines. Round her gathered Marot, Bonaventure Desperiers, Denisot, Peletier, Brodeau, and many other men of letters, while she protected Rabelais, Dolet, &c. For a time her influence with her brother was effectual, but latterly political rather than religious considerations made him discourage Lutheranism, and a fierce persecution was begun against both Protestants and freethinkers, a persecution which drove Desperiers to suicide and brought Dolet to the stake. Marguerite herself, however, was protected by her brother, and her personal inclinations seem to have been rather towards a mystical pietism than towards dogmatic Protestant sentiments. Nevertheless bigotry and the desire to tarnish the reputation of women of letters have led to the bringing of odious accusations against her character, for which there is not the smallest foundation. Marguerite died in 1549. By her first husband she had no children, by her second a son who died in infancy, and a daughter, Jeanne d'Albret, who became the mother of Henry IV. Although the poets of the time are unwearied

in celebrating her charms, she does not, from the portraits which exist, appear to have been regularly beautiful, but as to her sweetness of disposition and strength of mind there is universal consent.

Her literary work has not yet been given entirely to the world, but the printed portion of it makes her a considerable figure in French literature. It consists of the *Heptameron*, of poems entitled *Les Marguerites de la Marguerite des Princesses*, and of *Letters*. The *Heptameron*, constructed as its name indicates on the lines of the *Decameron* of Boccaccio, consists of seventy-two short stories told to each other by a company of ladies and gentlemen who are stopped in the journey homewards from Cauterets by the swelling of a river. It was not printed till 1558, ten years after the author's death. Internal evidence is strongly in favour of it having been a joint work, in which more than one of the men of letters who composed Marguerite's household took part. It is a delightful book, and strongly characteristic of the French Renaissance. The sensuality which characterized the period appears in it, but in a less coarse form than in the great work of Rabelais; and there is a poetical spirit which, except in rare instances, is absent from *Pantagruel*. The *Letters* are interesting and good. The *Marguerites* consist of a very miscellaneous collection of poems, mysteries, farces, devotional poems of considerable length, spiritual and miscellaneous songs, &c. Other poems, said to be of equal merit, are still unprinted, or have appeared only in part.

II. The second MARGUERITE (1523–1574), daughter of Francis I., married the duke of Savoy in 1559. She is noteworthy as having given the chief impulse at the court of her brother Henry II. to the first efforts of the Pléiade.

III. The third MARGUERITE (1553–1615), called more particularly Marguerite de Valois, was great-niece of the first and niece of the second, being daughter of Henry II. by Catherine de'Medici. She was born in 1553. When very young she became famous for her beauty, her learning, and the looseness of her conduct. She was married to Henry of Navarre, afterwards Henry IV., on the eve of St Bartholomew's Day. Both husband and wife were extreme examples of the licentious manners of the time, but they not unfrequently lived together for considerable periods, and nearly always on good terms. Later, however, Marguerite was established in the castle of Usson in Auvergne, and after the accession of Henry the marriage was dissolved by the pope. But Henry and Marguerite still continued friends; she still bore the title of queen; she visited Marie de' Medici on equal terms; and the king frequently consulted her on important affairs, though his somewhat parsimonious spirit was grieved by her extravagance. Marguerite exhibited during the rest of her life, which was not a short one, the strange Valois mixture of licentiousness, pious exercises, and the cultivation of art and letters, and died in 1615. She left letters and memoirs, the latter of which are admirably written, and rank among the best of the 16th century. She is the "Reine Margot" of anecdotic history and romance.

The best editions of the works of Marguerite d'Angoulême are—of the *Heptameron*, that of Leroux de Lincy, 3 vols., Paris, 1855; of the *Letters*, that of Genin, Paris, 2 vols., 1842–43; and of the *Marguerites*, that of Frank, Paris, 4 vols., 1873; the *Heptameron* is also obtainable in several cheap editions. The *Mémoires* of Marguerite de Valois are contained in the collection of Michaud and Poujoulat, and have been published separately by Guessard, Lalanne, Caboche, &c. (G. SA.)

MARIA THERESA (1717–1780), archduchess of Austria, queen of Hungary and Bohemia, and empress of Germany, was the daughter of the emperor Charles VI. of Austria, by his wife Elizabeth Christina of Brunswick-Wolfenbüttel, and was born in Vienna on May 13, 1717. By the Pragmatic Sanction of 1713, a settlement which was guaranteed by the principal states of Europe, her father had regulated the succession in the imperial family; and in 1724 accordingly, after the death of the archduke Leopold, her only brother, she was publicly declared sole heiress of the Austrian dominions. In 1736 she married Francis Stephen of Lorraine, who in the following year became grand-duke of Tuscany; and on October 20, 1740, she came to the throne, her husband (emperor in 1745) being declared co-regent. The events of her reign have been briefly summarized under AUSTRIA (vol. iii. p. 127–129) and HUNGARY (xii. 370). She died at Vienna on November 29, 1780. Of sixteen children whom she bore to Francis, ten reached maturity. Her sons were Joseph II., who succeeded his father as Holy Roman emperor in 1765; Leopold, grand-duke of Tuscany, afterwards the emperor Leopold II.; Ferdinand, duke of Modena; and Maximilian, elector of Cologne. Of her daughters the best-known is Marie Antoinette, the wife of Louis XVI. of France.

MARIANA, JUAN DE (1536–1624), a celebrated Spanish historian, was born of obscure parentage at Talavera de la Reina in 1536. He studied at the university of Alcalá, and was admitted at the age of seventeen into the Society of Jesus, where he soon attracted notice by his brilliant talents and extensive acquirements. Called to the Collegium Romanum in 1561, he there professed theology four years, and reckoned among his pupils Robert Bellarmine, afterwards the famous cardinal. He then passed into Sicily, where he remained for about two years, and in 1569 he was sent to Paris, where his expositions of the writings of Aquinas attracted large audiences. In 1574 the decline of his health compelled him to give up teaching, and he obtained permission to return to Spain; the rest of his life was passed at the Jesuits' house in Toledo, in a vigorous literary activity which was interrupted only by the molestations to which his too great independence, liberality, and candour exposed him. He died on February 17, 1624.

His great work, *Historiæ de Rebus Hispaniæ*, first appeared in twenty books at Toledo in 1592; ten books were subsequently added (1605), bringing the work down to the accession of Charles V., and in a still later abstract of events the author completed it to the accession of Philip IV. in 1621. It was so well received that Mariana was induced to translate it into Spanish. The first part of this in some respects new work (*Historia de España*) appeared in 1601; it was completed in 1609, and much enlarged and improved in three subsequent editions which appeared during the translator's lifetime. It has been frequently reprinted since 1624, both in Latin and in Spanish; and an English translation by J. Stevens appeared in 1699. Mariana's *History* is justly esteemed for the extent of the author's researches, for the general accuracy of his acquaintance with the materials at his command, for the sagacity of his reflexions and characterizations, and above all for the merit of his style, which, in its simplicity, vividness, and directness, has deservedly been compared to that of Livy. The modern student may regret but can hardly blame the credulity with which in too many cases he has without the least attempt at historical criticism adopted the "received traditions of his country." Of the other works of Mariana, the most interesting is his treatise *De Rege et Regis Institutione*, of which the first edition, dedicated to Philip III., appeared at Toledo in 1599. In its sixth chapter the question whether it is lawful to overthrow a tyrant is freely discussed and answered in the affirmative,—a circumstance which brought much popular odium upon the Jesuits, especially after the assassination of Henry IV. of France in 1610. See Bayle's *Dictionnaire* and Hallam's *Literary History*, part ii. chap. iv. A volume entitled *Tractatus VII. Theologici et Historici*, published by Mariana at Cologne in 1609, containing in particular a tract "On Mortality and Immortality," and another "De Mutatione Monetæ," was put upon the Index Expurgatorius, and led to the confinement and punishment of its author by the Inquisition. During his confinement there was found among his papers a criticism upon the Jesuits (*De los Enfermedades de la Compañia de Jesus y de sus Remedios*), which was believed to have been written by him. It was not printed until after his death (1625).

MARIAZELL, a village in the duchy of Styria, Austria, with about 1200 inhabitants, is very picturesquely situated in the valley of the Salza, amid the Styrian Alps. Its entire claim to notice lies in the fact that it is the most frequented sanctuary in Austria, being visited annually by about 100,000 pilgrims. The object of veneration is a miracle-working image of the Virgin, carved in lime-tree wood, and about 18 inches high. This was presented to the place in 1157, and is now reverently enshrined in a

chapel lavishly adorned with objects of silver and other costly materials. The large church of which the chapel forms part was erected in 1644 as an expansion of a smaller church built in 1363 by Louis I., king of Hungary, after a victory over the Turks. It possesses four lofty towers. In the immediate vicinity of Mariazell there is a very large and important iron foundry, formerly worked by Government, but now leased to a company.

MARIE ANTOINETTE, Josephe Jeanne (1755-1793), queen of France, was the fourth daughter of Maria Theresa and the emperor Francis I., and was born on the 2d November 1755, on the day of the great earthquake at Lisbon, and in the year in which the hereditary policy of enmity between the houses of France and Austria was changed to an alliance between them. From her earliest years she was destined by her mother to sustain this alliance, and was educated, with a view to a marriage with a French prince, by the Abbé de Vermond, who was to have a great influence on her future life. In 1770 Choiseul negotiated her marriage to the young dauphin, which took place on May 16 with the greatest pomp, but which was soon overshadowed by a terrible accident in Paris at the fête given in honour of the marriage. The dauphine soon found her position very difficult; she was but fourteen, and was intended by her mother to support the Austrian alliance and Choiseul at the court of France. This use of her daughters for political purposes has been recently denied by Von Arneth, the able editor of Maria Theresa's letters; but a consideration of the letters themselves confirms the idea, which was at the bottom of Marie Antoinette's unpopularity in France, that she was only an Austrian spy in a high position. She had hardly arrived at Paris, when her friend and the friend of the Austrian alliance, Choiseul, was dismissed from the ministry, and she was left alone to steer a difficult course by the advice of the Austrian minister, the Count de Mercy-Argenteau, whose reports of her daily doings to Maria Theresa have been published. In May 1774 Louis XV. died, and Marie Antoinette became queen of France. Through the first years of her reign she played a very important political part, but, except, as in the cases of Poland and the Bavarian succession, when her mother pressed her to maintain the alliance, she chiefly exerted her influence with regard to individuals, not to measures or policies. Thus she effected the dismissal of Turgot, and, by the Abbé de Vermond's advice, the sammons of Loménie de Brienne to the ministry, not from political but from personal motives, and obtained enormous presents for her intimate friends without thinking that they were interested in her for selfish motives of their own. This political rôle of hers, which was more than suspected, made her intensely unpopular to the French people, and this feeling was increased by her social mistakes. Her extravagance in dress and her passion for the card-table had greatly incensed and disgusted her mother; and, when her mother's death removed her only frank and bold adviser, she became more extravagant and more frivolous than ever. Her passion for play, her love of amusement, her intimacy with the Polignacs and their wild and dissipated society, her night visits to masked balls in Paris, and her favours to many officers of her guards and young foreigners at her court were the subject of ribald conversation in every coterie of Paris. The scandal of the diamond necklace, in which the queen was not to blame, spread her name with infamy all over France as if she had been guilty; and among the people her extravagance was regarded as a potent cause of their poverty and want. Such was her unpopularity when the states-general met in May 1789; she was believed to be debauched and dissipated, when her real faults were that she was frivolous and careless of public opinion, Austrian at heart, though queen of France, and opposed to Necker as she had been to Turgot, and to all the reforms and economies her husband, Bonhomme Louis, was willing to institute. From July 14 onward Marie Antoinette headed the party of reaction and armed opposition to the Revolution, and became unwittingly the means of her husband's unpopularity and downfall; for she always had influence enough to prevent his carrying out the frank, honest policy of reform which he desired, but not enough to make him adopt hers in its stead, and is to blame for his vacillations in decisive moments. Left to himself, Louis would, from the beginning of his reign, have been a reforming king like Charles III. of Spain, and the great outbreak might have passed over. To trace her policy minutely from 1789 to 1793 is made very difficult by the numerous pretended letters of hers which have been published, and till recently believed in. She inspired the collection of foreign troops round Paris, contrary to the king's opinion, and thus brought on the taking of the Bastille. She was present at the banquet at Versailles which caused the march of the women to Versailles and the transference of the royal family to Paris. When there, she still looked forward to undoing all that had been done, and would never frankly recognize her position. When brought into negotiation with Mirabeau, she refused to trust him or deal frankly with him. Had she done so, she would probably have established a strong constitutional government, but she would not have been the self-willed Marie Antoinette. He advised her to go with the king and royal family to some provincial capital, declare the royal adherence to all the early acts of the assembly, but declare also that its later acts were passed under constraint, and were null and void; but she must not do two things—she must not fly towards the frontier, else she would be suspected of seeking foreign aid, and she must not depend on the army but the people. She would not act while Mirabeau was alive,—she was too independent to act by any one's advice; but when he was dead she did what he had advised her not to do, fled towards the frontier, and to Bouillé's army. The royal family were stopped at Varennes, and brought back to Paris, but from that time were regarded as traitors to France. She had yet two more chances. She might have thrown herself into the hands of Barnave, Duport, and the constitutional party of the constituent assembly, who were ready to rally round their constitutional king, but she would not trust them or take their advice. When she was at the end of her power, when the Tuileries had been stormed, and she was in prison, and the republic proclaimed, Dumouriez was ready, after his victory of Valmy, to turn his army on Paris, dissolve the Jacobins, and re-establish the old constitution, but she would not trust him. It was her last chance. When once the republic was proclaimed, it was evident that Louis must die both to cement its foundations and to remove a dangerous centre of reaction; and in January 1793 Marie Antoinette became a widow, never to the last recognizing that she had sacrificed her husband to her obstinacy and self-will. Harrowing descriptions have been given of her treatment in prison during the few remaining months of her life, but, though she was separated from her children, she had every material comfort, no less a sum than 1110 livres being spent on her food alone between August and October, at the rate of 15 livres a day. At last her trial came on,—a mock trial indeed, as all those of the time, for her execution was determined before she came before the tribunal. Much has been said of the shameful charges made against her; but, shameful as they were, they were based on a confession made by her son, which, though probably forced from him and utterly false, was yet put in evidence. The trial was soon over, and on the same day, October 16, 1793, she was guillotined.

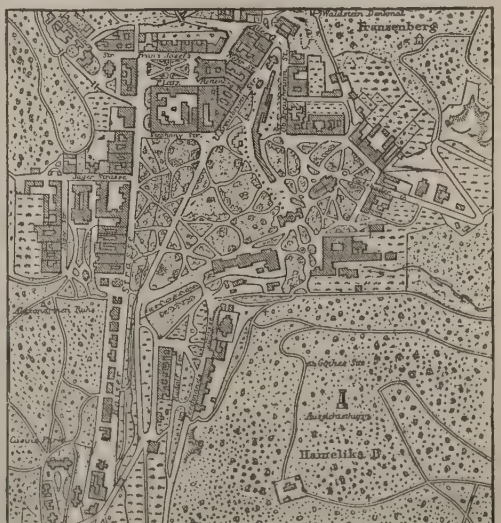
It is hard to speak of Marie Antoinette with justice; her faults were caused by her education and position rather than her nature, and she expiated them far more bitterly than was deserved. She was thoroughly imbued with the imperial and absolutist ideas of Maria Theresa, and had neither the heart nor the understanding to sympathize with the aspirations of the lower classes. Her love of pleasure and of display ruined both her character and her reputation in her prosperous years, and yet, after a careful examination of many of the libels against her, it may be asserted with confidence that she was personally a virtuous woman, though always appearing to be the very reverse. Innocence is not always its own protection, and circumspection is as necessary for a queen as for any other woman. Her conduct throughout the Revolution is heart-rending; we, who live after the troubled times, can see her errors and the results of her pride and her caprice, but at the time she was the only individual of the royal family who could inspire the devotion which is always paid to a strong character. In the Marie Antoinette who suffered on the guillotine we pity, not the pleasure-loving queen, not the widow, who had kept her husband against his will in the wrong course, not the woman, who throughout her married life did not scruple to show her contempt for her slow and heavy but good-natured and loving king, but the little princess, sacrificed to state policy, and cast uneducated and without a helper into the frivolous court of France, not to be loved, but to be suspected by all around her, and eventually to be hated by the whole people of France.

For lives and memoirs of Marie Antoinette before 1863, as well as engravings of her, the student is referred to a complete and careful bio-bibliography, contained in M. de Lescure's *La Vraie Marie Antoinette*, Paris, 1863. This work, however, contains many forged letters, purporting to be hers, and leads to the question of Marie Antoinette's published letters. There can be no doubt that very many fabrications by autograph makers for autograph collectors are published as authentic in D'Hunolstein, *Correspondance inédite de Marie Antoinette*, Paris, 1864; and in Feuillet des Conches, *Louis XVI., Marie Antoinette, et Madame Elisabeth, lettres et documents inédites*, Paris, 1865. The falsity of these letters was shown by Professor Von Sybel and by M. Geffroy in the *Revue des Deux Mondes*, and still more clearly in the latter's appendix to his *Gustave III. et la cour de France*, Paris, 1867. To study Marie Antoinette as she really lived, the student must consult Von Arneth's numerous publications on her and her mother and brothers, and particularly Arneth and Geffroy, *Marie Antoinette: Correspondance secrète entre Marie-Thérèse et le Comte de Mercy-Argenteau*, Paris, 2 vols., 1874, in which Marie Antoinette's daily life for ten years, from 1770–80, is described for her mother's own eyes. For the affair of the necklace read Carlyle's *Essay*. For her imprisonment, trial, and execution, see Campardon's *Tribunal Révolutionnaire*, vol. i., and the same author's *Marie Antoinette à la Conciergerie*, Paris, 1863. (H. M. S.)

MARIE DE FRANCE is one of the most interesting figures in the literary history of the Middle Ages. She is also one of the most mysterious. Nothing is known of her except from her own statements, which amount to little more than that her name was Marie and her country France, that she dedicated one of her works to an unnamed king, and another to a certain Count William. She is mentioned by Denis Pyramus, who was her contemporary, and who says that she was very popular, but gives no particulars. Attempts have been made to identify conjecturally the king and the count,—the most probable hypotheses being that the former was Henry III. of England, and the latter William Longsword of Salisbury; that is to say, Marie lived in the first half of the 13th century, and rather towards the beginning than the end of that half. Her work, which remains to us is entirely poetical, and by no means inconsiderable in extent. It falls naturally into three divisions. The first consists of *lais* or narrative poems in octosyllabic couplets. There are fourteen of them, the titles being *Gugemer*, *Equitan*, *Le Frêne*, *Le Bisclavaret*, *Lanval*, *Les deux amants*, *Yvenec*, *Le Laustic* ("the Nightingale"), *Milon*, *Le Chaitivel* ("the Unhappy One"), *Le Chèvrefeuille*, *Eliduc*, *Graelent*, *L'Épine*. The longest of these contains nearly twelve hundred lines; the shortest only just exceeds a hundred. The term *lai* is of Breton origin, and is believed to have had reference originally to the kind of music to which it was performed. But in Marie it is simply a short romance, generally of an amatory character. The merits of these poems are very great. They have much tenderness and delicacy of expression, flowing and melodious verse, and not a little descriptive power. The dialect is decidedly Norman in character, and English words occasionally occur, but are invariably explained in French. Some of these poems were paraphrased by the late Mr O'Shaughnessy in his *Lays of France* (London, 1872), but the translator indulged to such an extent in amplification that the effect is very dissimilar to that of the original. The second division of Marie's work is of less poetical but of greater general interest. It consists of an *Ysopet* (a general term in the Middle Ages for a collection of fables) of one hundred and three fables, of which Marie tells us that Henry Beauclerk translated it from Latin into English, and that for the love of Count William, "the most valiant of this realm," she herself rhymed it from English into French. The fables are exceedingly well told, with a liveliness, elegance of verse, and ingenious aptness of moral which make Marie a worthy forerunner of La Fontaine. The question has been debated whether the great fabulist was acquainted with her work. All that can be said is that, though it is by no means impossible, and from internal evidence not even wholly improbable, it cannot be said to be very likely. The third of Marie's works is a poem of two thousand three hundred verses, describing the purgatory of Saint Patrick, written at the request of an unidentified "prudom," or man of worship. Marie has been longer and better known than most of the poets of mediæval France, and perhaps she has been relatively a little overvalued, but her positive excellence is very considerable. Her style is a good example of the pure and highly organized language of the 13th century; and despite its great age it can be read by any person acquainted with modern French with a very small expense of attention, and with but slight use of glossaries.

The standard edition of Marie's works is by B. de Roquefort, 2 vols., Paris, 1820.

MARIENBAD, one of the prettiest and most frequented watering-places on the Continent of Europe, with a station (about 1¼ miles S.E. of the town) on the Kaiser Franz Josephs Railway, lies in a pleasant valley in the district of Tepl, in the north-west of Bohemia, about 18 miles south of Carlsbad, and nearly 2000 feet above the level of the



Plan of Marienbad.

sea. The gently-sloping hills which enclose it on all sides except the south are picturesquely wooded with fragrant pine forests. The town has an attractive and clean appearance, and is amply provided with buildings for the lodging and amusement of its thirteen thousand annual visitors, including a theatre and a large kurhaus. The handsome Roman Catholic church and the tasteful little

English church are among the chief ornaments of the place. The springs resemble those of Carlsbad, except that they are cold, and contain nearly twice the quantity of purgative salts. The water is used both internally and externally, and is deemed efficacious in disorders of the stomach and other organs, skin diseases, gout, and nervous complaints. About one million bottles are annually exported. The curative appliances of Marienbad also include the use of goats' milk whey, and peat, pine-cone, and gas baths. The climate is healthy and bracing, the mean annual temperature being about 45° Fahr. The springs of Marienbad, though previously used by the peasantry of the district, first came into general notice about the beginning of this century through the instrumentality of Dr Nehr, to whom a monument was erected here in 1857. They belong to the rich abbey of Tepl, which lies about 9 miles to the east. The permanent population of Marienbad was 2009 at the census of 1880.

MARIENBURG (in Polish, *Malborg*), the chief town of a circle in the district of Dantzic, Prussia, lies 30 miles to the south-east of Dantzic, in a fertile plain on the right bank of the Nogat, a channel of the Vistula, here spanned by a handsome railway bridge and by a bridge of boats. Marienburg contains a large chemical wool-cleaning work and several other factories, carries on a considerable trade in grain, wood, linen, feathers, and brushes, and is the seat of important cattle, horse, and wool markets. Its educational institutions include a gymnasium and a Protestant normal school. In the old market-place, many of the houses in which are built with arcades in the Italian style, stands a Gothic town-house, dating from the end of the 14th century. The town is also embellished with a good statue of Frederick the Great, who added this district to Prussia, and a monument commemorating the war of 1870–71. The population in 1880 was 9559. Marienburg is chiefly interesting from its having been for a century and a half the residence of the grand masters of the Teutonic order. The large castle of the order here was originally founded in 1274 as the seat of a simple commandery against the pagan Prussians, but in 1309 the headquarters of the grand master were transferred hither from Venice, and the "Marienburger Schloss" soon became one of the largest and most strongly fortified buildings in Germany. On the decline of the order in the middle of the 15th century, the castle passed into the hands of the Poles, by whom it was allowed to fall into neglect and decay. It came into the possession of Prussia in 1772, and was carefully restored at the beginning of the present century. This interesting and curious building consists of three parts, the Alte or Hohe Schloss, the Mittel Schloss, and the Vorburg. It is built of brick, in a style of architecture peculiar to the Baltic provinces, and is undoubtedly one of the most important secular buildings of the Middle Ages in Germany.

Of the numerous monographs published in Germany on the castle of Marienburg, it will suffice to mention here Büsching's *Schloss der Deutschen Ritter zu Marienburg*, Berlin, 1828; Voigt's *Geschichte von Marienburg*, Königsberg, 1824; and Bergau's *Ordenshaupthaus Marienburg*, Berlin, 1871.

MARIETTA, a city of the United States, the capital of Washington county, Ohio, lies on the right bank of the Ohio, at the mouth of the Muskingum, 85 miles south-east of Columbus, and is the eastern terminus of the Marietta and Cincinnati Railroad, and the southern terminus of the Cleveland and Marietta Railroad. The surrounding country being rich in petroleum, iron, and coal, the city has become the seat of no inconsiderable industry in the shape of oil-works, iron foundries, and machine-shops, a rolling mill, tanneries, and carriage, car, bucket, and chair factories. Marietta College, chartered in 1835, and maintained by voluntary endowment and subscription, is a flourishing institution, with eight instructors and a library of 25,000 volumes, occupying a fine group of buildings in the midst of extensive grounds. The population of the city has risen from 3175 in 1850 to 5444 in 1880. At the latter date the township, which includes the village of Harmar (1572), contained 8830 persons.

Marietta, founded in 1788 by General Putnam, and named in honour of Marie Antoinette, is the oldest town in Ohio. It is built on the site of a remarkable group of prehistoric monuments, the largest of which are two enclosures, respectively 40 and 20 acres in extent, formed by walls from 20 to 30 feet broad at the base, and still in some places 5 and 6 feet high. See Squier and Davis, *Ancient Monuments of the Mississippi Valley*.

MARIETTE, Auguste Ferdinand François, elder son of François P. Mariette, advocate and town-clerk of Boulogne-sur-Mer, was born in that town on the 11th of February 1821. Educated at the Boulogne municipal college, he distinguished himself in geometry, physics, chemistry, history, Latin, Greek, and English. He also evinced a remarkable talent for art. In 1839, when but eighteen years of age, he went to England in the capacity of professor of French and drawing at a boys' school at Stratford-on-Avon, which occupation he exchanged in 1840 for that of pattern-designer to a ribbon manufacturer at Coventry. Weary of ill-paid exile, he returned that same year to Boulogne, resumed his interrupted studies, and in March 1841 took his bachelor's degree (with honourable mention) at Douai. He now became a professor at the college where he had formerly been a student, and for some years supplemented his modest salary by giving private lessons, and writing on historical and archæological subjects for various local periodicals. In the meanwhile his cousin, Nestor L'Hôte, the friend and fellow-traveller of Champollion, died; and upon Auguste Mariette devolved the pious task of sorting the multitudinous papers of the deceased savant. The young man thenceforth became passionately interested in Egyptology, devoted himself to the study of hieroglyphs and Coptic, and in 1847 published a *Catalogue Analytique* of the Egyptian Gallery of the Boulogne Museum. He had now found his vocation, and in 1849, being appointed to a subordinate position in the Louvre, left Boulogne for Paris. Entrusted shortly after with a Government mission for the purpose of seeking and purchasing Coptic, Syriac, Arabic, and Ethiopic MSS. for the national collection, he started for Egypt in 1850. Soon after his arrival he made his celebrated discovery of the ruins of the Serapeum and the subterraneous catacombs of the Apis-bulls, buried for probably some two thousand years under the sands of the Libyan desert (see vol. vii. p. 773). His original mission being abandoned, funds were now advanced for the prosecution of his researches, and he remained in Egypt for four years, excavating, discovering, and despatching archæological treasures to the Louvre, of which museum he was, on his return, appointed an assistant conservator. In 1858, by permission of his own Government, he accepted the position of conservator of Egyptian monuments to the ex-khedive, Ismail-Pasha, and so removed with his family to Cairo. His history thenceforth becomes a chronicle of unwearied exploration and brilliant success. The pyramid-fields of Memphis and Sakkara, and the necropolises of Meydum, Abydos, and Thebes were ransacked for sepulchral treasures; the great temples of Denderah and Edfoo were disinterred, and, with their tens of thousands of inscriptions and bas-reliefs, restored to the light of day; important excavations were carried out at Karnak, Medinet-Habu, and Deir-el-Bahari; Tanis (the Zoan of the Bible) was partially explored in the Delta; and even Gebel Barkal in the far Soudan was made to yield monuments of the Ethiopic kings. The Sphinx was also bared to the rock-level, and the famous

granite and alabaster monument miscalled the "Temple of the Sphinx" was discovered. In the meanwhile Mariette, raised successively to the rank of bey and then of pasha, had founded the "École Française d'Égyptologie" and the "Institut Égyptien," and created *ab ovo* the museum at Bulak, the richest and by far the most interesting Egyptian collection in the world. Honours and orders were showered upon him. Poor in purse but rich in fame, he received in 1852 the grand cross of the Legion of Honour and of the Medjidie, in 1855 the Red Eagle (first class) of Prussia, in 1857 the Italian order of SS. Maurice and Lazarus, and in 1858 the Austrian order of Francis-Joseph. In 1873 the Academy of Inscriptions decreed to him the great biennial prize of 20,000 francs, and in 1878 he was elected a member of the Institute. He was also an honorary member of most of the learned societies of Europe. Though of herculean strength and indomitable energy, he was not proof against over-work of all kinds, physical, mental, and official. Prostrated in 1877 by a first attack of the insidious malady from which only death released him, he lingered for a few years, working to the last, and died at Cairo January 19, 1881. His remains, enclosed in an ancient Egyptian sarcophagus chosen by himself for that purpose, are interred within the precincts of the museum-garden at Bulak, facing the entrance to that unrivalled collection which is his own noblest monument.

Of Mariette's numerous and important contributions to the literature of Egyptology, we may here especially note the following works, which are not only distinguished for their erudition and accuracy, but for the exquisite grace of style with which they are written:—*Le Sérapéum de Memphis*, folio, 1857 and following years; *Dendérah*, five folios and one 4to, 1873–75; *Abydos*, two folios and one 4to, 1870–80; *Karnak*, folio and 4to, 1875; *Deir-el-Bahari*, folio and 4to, 1877; *Listes géographiques des pylônes de Karnak*, folio, 1875; *Catalogue du Musée de Boulaq*, six editions, 1864–76; *Aperçu de l'histoire d'Égypte*, four editions, 1864–74, &c. His last, and one of his most important works, *Les Mastabas de l'Ancien Empire*, text and illustrations facsimiled from the original MSS., folio, is now in course of publication, edited by Professor G. Maspero.

MARIGNOLLI, Giovanni de', a notable traveller to the far East of the 14th century, born probably prior to 1290, and sprung from a noble family in Florence. The family is long extinct, but a street near the cathedral (Via de' Cerretani) formerly bore the name of the Marignolli.

In vol. v. pp. 628–29 some account has been given of the extraordinary episode of intercourse between Europe and China in the first half of the 14th century. In 1338 there arrived at Avignon, where Benedict XII. held his court, an embassy from the great khan of Cathay, bearing letters to the pontiff from the khan himself, and from certain Christian nobles of the Alan race in his service. These latter represented that they had been eight years without a spiritual guide, and earnestly desired one. The pope replied to the letters, and appointed four ecclesiastics as his legates to the khan's court. The name of Marignolli, a Franciscan of some repute for learning, appears, as John of Florence, third on the letters of commission. We know not what became of his colleagues; he was the chief if not the sole envoy who actually went.

The mission left Avignon in December 1338, picked up the Tartar envoys at Naples, and sailed across the Black Sea to Caffa, whence they travelled to the court of Mohammed Uzbek, khan of the Golden Horde, at Sarai on the Volga. The khan entertained them hospitably during the winter of 1339–40, and then sent them across the steppes to Armalec or Almaligh, the northern seat of the house of Chaghatai, in what is now the province of Ili. "There," says Marignolli, "we built a church, bought a piece of ground . . . . sung masses, and baptized several persons, notwithstanding that only the year before the bishop and six other minor friars had there undergone glorious martyrdom for Christ's salvation." Quitting Almaligh in 1341, they seem to have reached Peking (by way of Kamil or Hami) in May or June 1342. They were well received by the reigning khan, the last of the Mongol dynasty in China.

"The grand kaam, when he beheld the great horses (*dextrarios*) and the pope's presents, with his letter, and that of King Robert (of Naples) too, with their golden seals, and when he saw us also, rejoiced greatly, being delighted, yea exceedingly delighted with everything. . . . And when I entered the kaam's presence, it was in full festival vestments, with a very fine cross carried before me, and candles and incense, whilst *Credo in unum Deum* was chaunted, in that glorious palace where he dwells. And when the chaunt was ended I bestowed a full benediction, which he received with all humility."

An entry in the Chinese annals fixes the year of Marignolli's presentation by its mention of the arrival of the great horses from the kingdom of Fulang (*Farang* or Europe), one of which was 11 feet 6 inches in length, and 6 feet 8 inches high, and black all over!

Marignolli stayed at Peking or Cambalec three or four years, after which he travelled through eastern China to Zayton or Chinchew (*q.v.*), quitting China apparently in December 1347, and reaching Columbum (Kaulam or Quilon in Malabar) in Easter week of 1348. At this place he found a church of the Latin communion, probably founded by Jordanus of Séverac, who had been consecrated bishop of Columbum by Pope John XXII. in 1328. Here Marignolli remained sixteen months, after which he proceeded on what seems a most devious voyage. First he visited the shrine of St Thomas near the modern Madras, and then proceeded to what he calls the kingdom of Saba, and identifies with the Sheba of Scripture, but which seems from various particulars to have been Java. Taking ship again for Malabar on his way to Europe, he encountered great storms, of which he gives an imaginative account:—

. . . . "The sea as if in flames, and fire-spitting dragons flying by, which, as they passed, slew persons on board the other junks, whilst ours remained untouched, by God's grace, and by virtue of the Body of Christ which I carried with me, and through the merits of the glorious Virgin and of St Clare."

They found shelter in the little port of *Pervilis* (Beruwala or Berberyn) in the south-west of Ceylon; but here the legate fell into the hands of "a certain tyrant Coya Jan (Khoja Jahán), an eunuch and an accursed Saracen," who professed to treat him with all deference, but detained him four months, and plundered all the gifts and Eastern rarities that he was carrying home. This detention in "Seyllan" enables Marignolli to give a variety of curious particulars regarding Adam's Peak and other marvels. After this we have only fragmentary notices, showing that his route to Europe lay by Ormuz, the ruins of Babel, Baghdad, Mosul, Aleppo ("where there were many Christians who dressed after the Latin fashion, and spoke a language very near the French; at any rate like the French of Cyprus"), and thence to Damascus and Jerusalem. In 1353 he arrived at Avignon, and delivered a letter from the great khan to Pope Innocent VI. In the following year the emperor Charles IV., on a visit to Italy, made Marignolli one of his chaplains. Soon after, the pope made him bishop of Bisignano; but he seems to have been in no hurry to reside there. He appears to have accompanied the emperor to Prague; in 1356 he is found acting as envoy to the pope from Florence; and in 1357 he is at Bologna. We know not when he died. The last trace of Marignolli is a letter addressed to him, which was found last century among the records in the Chapter Library at Prague. The writer is an unnamed bishop of Armagh, easily identified with Richard Fitz Ralph, a strenuous foe of the Franciscans, who had broken lances in controversy with Ockham and Burley. The letter implies that some intention had been intimated from Avignon of sending

Marignolli to Ireland in connexion with matters then in debate. The wrath of Fitz Ralph is sorely stirred at this, and he brandishes the shillelah in a style of energetic metaphor very like what we have been used to from like quarters in later days.

Fitz Ralph's contemptuous language had probably a good deal of foundation. The fragmentary notes of Marignolli's Eastern travels often contain most vivid remembrance and graphic description, but combined with an incontinent vanity, and an incoherent lapse from one thing to another, matched by nothing in literature but the conversation of Mrs Nickleby. They have no claim to be called a narrative, and it is with no small pains that anything like a narrative can be pieced out of them. Indeed the mode in which they were elicited curiously illustrates how little mediæval travellers thought of publication. The emperor Charles, instead of urging his chaplain to write a history of his vast journeys, set him to the repugnant task of recasting the annals of Bohemia; and he consoled himself by salting the insipid stuff by interpolations, *à propos de bottes*, of his recollections of Asiatic travel

Nobody seems to have noticed the work till 1768, when the chronicle was published in vol. ii. of the *Monumenta Hist. Bohemiæ nusquam antehac edita* by Father Gelasius Dobner. But, though Marignolli was thus at last in type, no one seems to have read him till 1820, when an interesting paper on his travels was published by J. G. Meinert. The late Professor Kunstmann of Munich also devoted to the subject one of a series of very intelligent papers on the ecclesiastical travellers of the Middle Ages. And the whole of the passages bearing on the journey were excerpted, translated, and commented on by Col. H. Yule in a collection printed in 1866.

MARIGOLD. This name has been given to several plants, of which the following are the best known:—*Calendula officinalis*, L., the pot-marigold; *Tagetes erecta*, L., the African marigold; *T. patula*, L., the French marigold; and *Chrysanthemum segetum*, the corn marigold. All these belong to the order *Compositæ*; but *Caltha palustris*, L., the marsh marigold, is a ranunculaceous plant.

The first-mentioned is the familiar garden plant with large orange-coloured blossoms, and is a native of the meadows of southern Europe (DC., *Prod.*, vi. p. 451). It is unisexual, the "ray" florets being female, the "disk" florets male. This and the double variety have been in cultivation for at least three hundred years, as well as a proliferous form, *C. prolifera*, or the "fruitful marigolde" of Gerard (*Herball*, p. 602), in which small flower-heads proceed from beneath the circumference of the flower. The figure of "the greatest double marigold," *C. multiflora maxima*, given by Gerard (*l.c.*, p. 600) is larger than most specimens now seen, being 3 inches in diameter. He remarks of "the marigolde" that it is called *Calendula* "as it is to be seene to flower in the calends of almost euerie moneth." It was supposed to have several specific virtues, but they are now discredited. "The marigold, that goes to bed wi' the sun," is mentioned by Shakespeare, *Winter's Tale*, iv. 3.

*Tagetes patula*, L., and *T. erecta*, L. (DC., *Prod.*, v. p. 643), the French and African marigolds, are natives of Mexico, and are equally familiar garden plants, having been long in cultivation. Gerard figures four varieties of *Flos africanus*, of the single and double kinds (*l.c.*, p. 609); but they do not appear to be specifically distinct; indeed Parkinson (*Par.*, p. 303, 1629) regarded them as one. Besides the above species the following have been introduced later, *T. lucida*, Cav., *T. signata*, also from Mexico, and *T. tennifolia*, Cav., from Peru (Hemsley's *Handbook of Hardy Trees, &c.*, p. 247).

*Chrysanthemum segetum*, L., the yellow corn marigold, is indigenous to Great Britain, and is frequent in corn-fields in most parts of England. A decoction of the fresh plant gathered before flowering is acrid, and is said to be useful medicinally. When dried it has been employed as hay It is also used in Germany for dyeing yellow (Baxter, *Brit. Gen. of Pl.*, vol. iv. 306). Gerard observes that in his day "the stalke and leaues of Corne Marigolde, as Dioscorides saith, are eaten as other potherbes are."

*Caltha palustris*, L., the marsh marigold, the "winking Mary-buds" of Shakespeare (*Cymb.*, ii. 3), is a common British plant in marshy meadows and beside water. It bears cordate leaves, the flowers having a golden yellow calyx but no corolla, and blossoming in March and April. The flower-buds preserved in salted vinegar are a good substitute for capers. A double-flowered variety is often cultivated, and is occasionally found wild (Baxter, *l.c.*, vol. ii. 153).

MARINES. With all maritime nations, especially if they be insular and capable of taking the offensive in war, there must frequently be cases in which naval operations can be supplemented by the landing of a force. The armament, equipment, and discipline of the armies and navies of such nations were in early days practically alike. But with the introduction of more regular levies and better organization arose the necessity for having on board ships-of-war an armed body organized to meet the altered condition of things. Sailors were but engaged for periods during which ships were commissioned; and their previous history and training did not tend to furnish the material required. Regular armies on shore called for disciplined forces afloat,—that is to say, for marines, or sea soldiers, who should have the steadiness of the troops of the line, be accustomed to the peculiar duties of ship life, and be subordinate to the naval authorities.

Previous to 1664 the British navy had been manned chiefly by "impress"; but in that year an order in council appeared, authorizing the formation of a force of 1200 soldiers, in six companies, to be raised for sea service during the Dutch War. Probably it was recruited from the London Trained Bands, as the Royal Marines, with the 3d battalion of the Grenadier Guards, the East Kent Regiment, and the Royal London Militia, alone possess the privilege of marching through the city with colours flying and bayonets fixed. Recruits were also obtained from the foot guards; and in 1672 companies of the guards were employed on shipboard. The Army List of 1684 shows for the first time the organized battalion of marines, in H.R.H. the duke of York and Albany's maritime regiment of foot or "Admiral's Regiment," which, in that year, mustered on Putney Heath twelve companies, with a full proportion of officers. This stood third in seniority in the line, and eventually became the Coldstream Guards; the 4th, or "Holland Regiment," which also sent companies to sea, and had like the above regiment been raised by the City of London, taking its place as 3d or "Old Buffs." Several other maritime regiments were successively formed and disbanded, until, in 1702, Queen Anne directed the addition to the army of six regiments as a marine corps, while six existing regiments were also appointed "for sea service." These were done away with in 1714, three only being retained, as the 30th, 31st, and 32d of the line. Independent companies, for service in the West Indies, were also formed, becoming in 1742 the 49th foot. In 1739 six fresh regiments were levied, and augmented in 1742 to ten, of 1000 men in ten companies each; while three others were collected in America for colonial duty. Though commanded by generals and colonels of the army, they were to be quartered in the neighbourhood of the dockyards at Portsmouth, Sheerness, Chatham, Deptford, Woolwich, and Plymouth; and the proportion of officers, viz., 100 men with a captain to twenty with a subaltern, was fixed for the different classes of vessels. No field officer was embarked unless a full battalion were sent. In

1745 two other battalions were specially raised for service at Cape Breton, becoming finally the 50th and 51st foot; and in 1746 the ten regiments were restored to the army, taking rank from the 44th to the 53d. Previous to their disbandment as marines they had been partially under the orders of the lord high admiral.

By an order in council of 1755 a force of 5000 men in 50 companies was raised and definitely placed under the naval authorities. They were to be stationed at Chatham, Portsmouth, and Plymouth, the 4th or Woolwich division not being added until 1805; and this body was gradually increased to 19,000 men in 1762, but reduced in 1763 to about 4000. Commissions ceased to be purchasable, but exchange with the army was, for a time, sanctioned. Naval admirals and captains were appointed generals and colonels of marines in 1760, in consequence of a representation from the commandants of divisions that there was an insufficient number of field officers "for the discipline of the service." This absurd anomaly existed until 1833, when these useless sinecures were abolished.

The revolt of the American colonies in 1775 led, again, to an increase in the establishment, which by 1783 had reached 25,291 men,—followed by a reduction to 4495 the ensuing year. So urgent was the demand for marines during the struggle that men were frequently embarked untrained; yet, so popular was the service, they still "recruited better in every part of the island" than the army. Owing to this unwise policy of reduction, the force, on the outbreak of the French War in 1793, had to be supplemented, as formerly, by companies from the line; and at its conclusion the marine corps again reached a total strength of more than 30,000 men. But there had been differences between the military and naval authorities as to the employment of soldiers from the army; so that from 1815, when the numbers again fell to about 6000, there has been a steady increase, until an establishment suitable to the wants of the navy has been fixed. During the long war, moreover, the necessity for the formation of a body of marine artillery had become increasingly apparent. The services of marines in this capacity had been previously demanded during the American War, when they were employed in the half-moon battery and citadel at Halifax, and elsewhere in batteries on shore, as some of them had been "trained in the service of great guns" by Lieutenant Gillespie of the Royal Artillery. By an order in council of the 18th August 1804, therefore, "in consequence of the inconvenience of embarking the Royal Artillery," it was directed that one company of marine artillery, composed of the most intelligent and experienced officers and men, should be formed at each division to be employed for the training of the infantry, so as to embark efficient artillerymen in other vessels besides "bombs." This force suffered a reduction to two companies in 1822, since which date it also has been steadily increased; and in 1862 the artillery companies were separated from the light infantry and formed into a separate division at Fort Cumberland, Portsmouth, whence the headquarters were transferred to Eastney in 1869. In 1869 the Woolwich division was abolished, a depôt for the training of recruits being formed at Walmer. At present the Royal Marine force numbers 48 companies of infantry and 16 of artillery, showing a total force of 2532 artillery and 9862 infantry, at an expenditure of £913,456.

Each division of Royal Marines has a total force of 16 companies, with a colonel commandant, second commandant, 4 lieutenant-colonels, 14 majors, 20 captains, and 42 subalterns, inclusive of the divisional staff of instructors of gunnery, musketry, &c. The headquarter staff, in London, consists of a deputy and an assistant adjutant-general, &c.; and there are, in addition, three generals, three lieutenant-generals, and six major-generals on the active list. The men are recruited by special parties; they are enlisted for twelve years, with permission to re-engage for nine more. All recruits undergo their preliminary training at Walmer, and are then drafted to the several divisions,—those who reach a higher standard being allowed to volunteer for the artillery. The standard for infantry and artillery, and the system of pay, equipment, pension, and divisional administration, are similar to those of the line and Royal Artillery respectively. Officers are obtained by open competition from the pass-lists for entrance to the Military Academy, Woolwich, and the Royal Military College, Sandhurst. The successful infantry candidates are drafted to their several divisions, and undergo a course of instruction under the military instructor to the corps,—those for the artillery receiving a special training for two years at the Royal Naval College, Greenwich.

The Royal Marines, reckoning as part of the naval forces, are accounted for in the navy estimates; though the names of the officers appear both in the Army and Navy Lists. They are particularized in the Army Act as subject to military law at stated times, serving on shore under the Act and the regulations in force in the garrisons, where they perform the same duties as the land forces. Afloat they are subject to the Naval Discipline Act; and a Marine Mutiny Act was formerly passed annually for the "regulation of Her Majesty's Royal Marine forces while on shore," stating that they were under the direction of the lord high admiral, &c. On board ship their duties are of a purely military character, being confined to guard mounting, assisting to man boats for shore operations, and helping to form the crews for the heavy guns. Though under the supreme command of the naval authorities, they are only obliged to aid in work on deck, and when landed are entirely commanded by their own officers.

The war services of the corps are so numerous that they can be but briefly referred to. First employed at Cork in 1690, they have been present in nearly all the actions in which the navy has since then been engaged; and between that date and 1800 they took part in 227 sea fights and 70 important operations on shore. At Gibraltar and Manila, at Belleisle and Bunker's Hill, at Negapatam, the Cape, and Acre, they earned the special commendation of the leaders, as well as for Lord Howe's victory, and the great sea fights of Camperdown, Cape St Vincent, and the Nile. Nor were their enemies backward in recognizing their worth. At Belleisle the French, in describing the troops whose valour had been most conspicuous, designated the battalions of marines "les petits grenadiers"; and at Acre General Berthier bore testimony to the conspicuous gallantry of Major Oldfield, who fell in the attack on the fortress. From 1800 to 1815 they saw constant service in 99 coast operations and 142 naval actions. After the landing at Aboukir Bay in 1801 the "Bull Dogs" received high praise for the way in which they had done their work. At the siege of Gaeta, at Rosas, and at Santa Maura, the marines again distinguished themselves; and they took part in the decisive battles at Copenhagen, Trafalgar, San Domingo, and the Dardanelles. Three battalions were also specially brigaded with the line for active service in America and Holland in 1813–15. Since that period the marines have shared in the naval actions at Algiers, Navarino, Acre, the Baltic, and Black Sea, and have fought by the side of the land forces at the Cape, in India, China, New Zealand, Abyssinia, Ashantee, and Zululand, as also in those numerous petty skirmishes in which the navy has been so repeatedly engaged. In the bombardment of Alexandria (1882), and in the operations that followed it, the corps has again seen service by sea and land. Nor have their services been less important in other cases. Though forming part of the ships' companies, and therefore at times suffering from the same grievances, they have always been faithful to their trust. In 1797, a period of much sedition throughout the country, all efforts to shake their allegiance were fruitless, and the duke of York especially commended their loyalty and zeal. Between that year and 1802, after the mutinies of the Nore, Spithead, and Bantry Bay, of the "Temeraire," "Castor," "Impétueux," "Hermione," "Gibraltar," and "Excellent," the marines were publicly thanked for their devotion.

As part of a ship's company in naval actions, as a force landed to assist in coast operations, and as troops acting in concert with the army, the marines have won distinction and the commendation of both naval and military authorities for two hundred years. The motto of the corps, "Per mare per terram," needs no explanation; the title "Royal" was added in 1802 "for its many and varied services during the war," and its former facings were altered from white to royal blue; it was also in 1820, by an order in council, placed next in seniority to the 49th Regiment. In 1827 the globe, surrounded by the laurel wreath, for the siege of Belleisle, together with "Gibraltar," in commemoration of the services performed there, was added by George IV. In 1855 the infantry branch of the corps became "light infantry."

Although in the "armed strengths" of the great European powers marines and marine artillery are mentioned, these troops have little in common with those in the British navy. In France their duties are to garrison the five military ports and colonies, and to take part in marine and other wars. In Germany the marine

battalions and artillery divisions at Kiel and Wilhelmshafen are intended for coast defence only. In Holland, Austria, and Italy also they have a military organization, but do not form a recognized part of the complements of sea-going ships. America alone employs marines in the same manner as England; and they have won, as their British comrades have, the approbation of the naval authorities and, on nineteen occasions, the thanks of Congress. Admiral Farragut's opinion that "the marine guard is one of the great essentials of a man-of-war" is corroborated by that of Admiral Wilkes, who considered that "marines constituted the great difference between a man-of-war and a privateer." Formed in 1775 for the "publick defense," they rank as the oldest force in the American service; and since that time they have shared in land and sea operations in all parts of the world. In the famous battles between the "Bonhomme Richard" and "Serapis" in 1777, and in that between the "Chesapeake" and "Shannon," they displayed brilliant gallantry; and while on the one hand they at Derne in 1803 first planted the American flag on a fortress of the Old World, for which exploit "Tripoli" is inscribed on their colours, they on the other shared in the hard fighting of the Mexican war as well as all the important coast actions of the civil war of 1861–65. A proposal to incorporate them with the army after the struggle met with universal condemnation from the authorities best qualified to judge of their value. At present they number seventy-eight officers and two thousand men under the command of a commandant, who ranks as brigadier-general, with headquarters at Washington. Their administration, organization, and equipment are, as in England, identical with those of the soldiers of the line. They are enlisted for five years, must be 5 feet 6 inches in height, between eighteen and thirty-five years of age, and able to read and write. The complement on board ship varies from thirteen to fifty-one officers and men, depending on the rating of the vessel. Their device is a globe resting on an anchor and surmounted by an eagle. "Ever faithful" is the title which Captain Luce, the historian of the force, appropriately applies to them. (C. C. K.)

MARINI, or MARINO, GIAMBATTISTA (1569–1625), Italian poet, was born at Naples on October 18, 1569. At an early age he secured the powerful patronage of Cardinal Aldobrandini, whom he accompanied from Rome to Ravenna and Turin. His ungoverned pen and disordered life compelled him to take refuge from 1615 to 1622 in Paris, where he was favourably recognized by Mary de' Medici. He died at Naples on March 25, 1625. See ITALY, vol. xiii. p. 511.

MARINUS I. (MARTINUS II.) succeeded John VIII. in the pontificate about the end of December 882. On three separate occasions he had been employed by the three popes who preceded him as legate to Constantinople, his mission in each case having reference to the controversy excited by Photius. Among his first acts as pope were the restitution of Formosus, cardinal bishop of Porto, and the anathematizing of Photius. He died in May or June 884, his successor being Adrian III.

MARINUS II. (MARTINUS III.), pope from 942 to 946, was preceded by Stephen IX., and followed by Agapetus II.

MARION, FRANCIS (1732–1795), American general, was born in 1732 at Winyah, near Georgetown, South Carolina. In 1759–61 he served as lieutenant in expeditions against the Cherokees, and in 1775 he was elected a member of the provincial congress of South Carolina. This voted two regiments of infantry, and Marion was elected captain in the second. He was made lieutenant-colonel after the defence of Fort Moultrie at the entrance of Charleston harbour (June 28, 1776), and was present at the unsuccessful attack on Savannah, September 1779. In August he joined Gates, but was detached a few days before Gates's defeat at Camden on August 16; at Nelson's Ferry, on the 20th, he rescued one hundred and fifty of the prisoners from a strong guard. He soon received a general's commission. Pursued by Tarleton and Wemyss, he was driven to North Carolina, but soon returned. After successful skirmishes against superior forces, he formed a camp at Snow's Island in the midst of the swamps of the Pedee and the Santee. In March 1781 he defeated Watson at Black River; but meanwhile Doyle had destroyed Marion's camp. In April Lee and Marion took Fort Watson, and in May Fort Motte. In June Greene detached Sumter with Marion and others to make an incursion into the low country. At Quinby Marion's men fought well against Coates; and in August he made a forced march to Parker's Ferry and rescued Colonel Harden, pressed by a superior force. At Eutaw Springs he commanded the right under Greene. After the British retreat to Charleston, Marion went to an important session of the colonial assembly; on the very day that he returned to his brigade, February 24, 1782, it was surprised and dispersed, Marion arriving too late to recover the day. After the war he occupied himself with farming. He died February 27, 1795.

MARIONETTES (probably from *morio*, a fool or buffoon), FANTOCCINI (from *fantino*, a child), or PUPPETS (*poupée*, a baby or doll), are figures, generally below life-size, suspended by threads or wires and imitating with their limbs and heads the movements of living persons.

The high antiquity of puppets appears from the fact that figures with movable limbs have been discovered in the tombs of Egypt and among the remains of Etruria; they were also common among the Greeks, from whom they were imported to Rome. Plays in which the characters are represented by puppets or by the shadows of moving figures, worked by concealed performers who deliver the dialogue, are not only popular in India and China at the present day, but during several centuries past maintained an important position among the amusements of the people in most European countries. Goethe and Lessing deemed them worthy of attention; and as late as 1721 Le Sage wrote plays for puppets to perform. Every one remembers in Don Quixote "the curious puppet show, which represents the play of Melisandra and Don Gayferos, one of the best shows that has been acted time out of mind in this kingdom." Reference to puppet shows is frequent in English literature from Chaucer onward. Thus Davenant says:—

> "And man in chimney hid to dress
> Puppet that acts our old Queen Bess,
> And man that, while the puppets play,
> Through nose expoundeth what they say."

The earliest performances in English were drawn or founded upon Bible narratives and the lives of the saints, in the same vein as the "morality" plays which they succeeded. Popular subjects in the 16th century were *The Prodigal Son* and *Nineveh, with Jonah and the Whale*. And in a pamphlet of 1641, describing Bartholomew Fair, we read, "Here a knave in a fool's coat, with a trumpet sounding or a drum beating, invites you to see his puppets. Here a rogue like a wild woodman, or in an antic shape like an incubus, desires your company to view his motion." In 1667 Pepys recorded how, at Bartholomew Fair, he found "my Lady Castlemaine at a puppet play, Patient Grizill." Besides *The Sorrows of Griselda*, other puppet plays of the period were *Dick Whittington*, *The Vagaries of Merry Andrew*, and *The Humours of Bartholomew Fair*. Powell's noted marionette show was the subject of an article in *The Tatler*, 1709, and again in *The Spectator*, 1711. The latter refers also to Pinkethman, a "motion-maker," in whose scenes the divinities of Olympus ascended and descended to the strains of music. An idea of the class of representation may be gathered from an advertisement of Crawley, a rival of Pinkethman, which sets forth—"The Old Creation of the World, with the addition of Noah's Flood," also several fountains playing water during the time of the play. The best scene represented "Noah and his family coming out of the ark, with all the animals two by two, and all the fowls of the air seen in a prospect sitting upon trees; likewise over the ark is the sun rising in a gorgeous manner; moreover a multitude of

angels in a double rank," the angels ringing bells. "Likewise machines descending from above, double, with Dives rising out of hell and Lazarus seen in Abraham's bosom; besides several figures dancing jiggs, sarabands, and country dances, with the merry conceits of Squire Punch and Sir John Spendall." Yates showed a moving picture of a city, with an artificial cascade, and a temple,—with mechanical birds in which attention was called to the exact imitation of living birds, the quick motion of the bills, just swelling of the throat, and fluttering of the wings. The puppets were wax figures 5 feet in stature. Toward the end of the 18th century, Flockton's show presented five hundred figures at work at various trades. Brown's Theatre of Arts showed at country fairs, from 1830 to 1840, the battle of Trafalgar, Napoleon's army crossing the Alps, and the marble palace of St Petersburg; and at a still later date Clapton's similar exhibition presented Grace Darling rescuing the crew of the "Forfarshire" steamer wrecked on the Fern Islands, with many ingenious moving figures of quadrupeds, and, in particular, a swan which dipped its head into imitation water, opened its wings, and with flexible neck preened and trimmed its plumage. In these mechanical scenes the figures, painted upon a flat surface and cut out, commonly of pasteboard, are slid along grooves arranged transversely in front of the set scenery, the actions of legs and arms being worked by wires from the hands of persons below the stage, though sometimes use is made of clockwork.

Marionettes proper, and the dolls exhibited in puppet shows (not including Punch and his companion actors), are constructed of wood or of pasteboard, with faces of composition, sometimes of wax; and each figure is suspended by a number of threads to a short bar of wood which is commonly held in one hand of the hidden performer while the finger of his other hand poses the figure or gives action to it by means of the threads. In the mode of constructing the joints, and the greater elaboration with which the several parts of the limbs are supported and moved, and especially in the fine degrees of movement given to the heads, marionettes have been so improved as to present very exact imitations of the gestures of actors and actresses, and the postures and evolutions of acrobats; and, in addition, ingenious exhibitors such as Theodon, who introduced many novelties from twenty to thirty years ago, have employed mechanical arrangements for accomplishing the tricks of pantomime harlequinade. Among the puppet personages presented in the small street shows are generally included a sailor who dances a hornpipe, a hoop-dancer, a dancer of the Highland fling, a wooden-legged pensioner, a vaulter on a pole also balancing two chairs, a clown playing with a butterfly, a dancing figure without head until the head rises out of the body, gradually displaying an enormously long neck, a juggler tossing gilt balls which, sliding up and down upon tight invisible threads, fall into his hands again, a milk-woman carrying buckets out of which fly white dolls, and a skeleton, seen at first in scattered parts lying about the stage, but piece successively flying to piece, the body first sitting up, then standing, and finally capped by the skull, when the completed figure begins to dance.

*Ombres Chinois* are the shadows of figures projected upon a stretched sheet of thin calico or a gauze scene painted as a transparency. The cardboard flat figures are held behind this screen, illuminated from behind,—the performer supporting each figure by a long wire held in one hand while wires from all the movable parts terminate in rings in which are inserted the fingers of his other hand.

MARIOTTE, Edme (died 1684), a celebrated French physicist, was a native of Burgundy. He lived chiefly near Dijon as prior of St Martin sous Beaune, and was one of the first members of the Academy of Sciences, which was founded at Paris in 1666. He died at Paris May 12, 1684. The first volume of the *Histoire et Mémoires de l'Académie* (1733) contains many original papers by him upon a great variety of physical subjects, such as the motion of fluids, the nature of colour, the notes of the trumpet, the barometer, the fall of bodies, the recoil of guns, the freezing of water, &c. His *Essais de Physique*, four in number, of which the first three were published at Paris between 1676 and 1679, are his most important works, and form, together with an elaborate treatise on the percussion of bodies, the first volume of the *Œuvres de Mariotte* (2 vols., Leyden, 1717). The second of these essays ("De la Nature de l'Air") contains the statement of the law connecting the pressure and volume of a gas which, though very generally called by the name of Mariotte, was discovered seven years before by Boyle. The fourth essay is a systematic treatment of the nature of colour, with a description of many curious experiments and a discussion of the rainbow, halos, parhelia, diffraction, and the more purely physiological phenomena of colour. The discovery of the blind spot is noted in a short paper in the second volume of his collected works.

MARITIME LAW. See Sea Laws.

MARITIME PROVINCE (Russian, *Primorskaya Oblast*), a province of the Russian empire, and part of the general-governorship of Eastern Siberia, is a strip of territory which extends along the Siberian coast of the Pacific from Corea to the Arctic Ocean, and also includes the peninsula of Kamchatka (*q.v.*), the island of Saghalien or Sakhalin, and several small islands scattered along the coast. Its western boundary stretches northwards from the Corean town of King-hing (41° 45′ N. lat.) by Lake Khangka and along the Usuri, keeping to the eastward of the hilly tracts and prairies of northern Manchuria; it then follows an imaginary line which runs due north from the mouth of the Usuri to the bay of Udskoy, separating the province from the lowlands and mountain wildernesses of the Amur province; it next runs along the Stanovoy watershed between the Pacific and the Arctic Ocean, leaving to the west the elevated tracts of the Siberian plateau, and finally it crosses the spurs of this plateau through barren *tundras* belonging to Yakutsk, reaching the Arctic Ocean at the Chaunskaya Bay (70° N. lat.). The province has a length of 2300 miles and a width varying from 40 to 420 miles; it covers an area of 730,000 square miles, and exhibits very great varieties of climate, scenery, and population. The northern part, known as the land of the Chukchees, occupies the north-eastern peninsula of Asia between the Arctic Ocean on the one side and the Seas of Behring and Okhotsk on the other, and has the character of a barren plateau from 1000 to 2000 feet high, deeply indented by the rivers of the Anadyr basin, and by long fiords, such as the Koluchin Bay (the wintering-place of Nordenskjöld's "Vega"), the Gulf of Anadyr, and the Bays of Penzhina and Ghizhiga. To the north this plateau is bordered by a chain of mountains, the highest known within the Arctic circle, several summits of which reach a height of 8200 feet (Makachinga peak and others), while the promontories by which the Asiatic continent terminates towards Behring Strait—Serdtze-kamen, Cape Vostochnyi (the most easterly point of Asia), and Cape Chukotskiy—have heights ranging from 1000 to 2000 feet. Only lichens and mosses, with a few dwarf species of Siberian trees, cover this district, in marked contrast to the rich forests of the corresponding part of Arctic America. The fauna, however, is far richer than might have been expected, owing to the migrations of animals along the plateaus of Eastern Siberia, which extend in a north-eastern direction from the very heart of Asia to Behring Strait. The fauna is further enlarged by a few American birds and mammals, which cross the strait when it is frozen. This country, and still more the seas by which it is surrounded, have been for the last two centuries the paradise of hunters, and have supplied Siberian trade with its best furs. Entire species of animals have been exterminated within this short period; the renowned blue fox and black sable have nearly disappeared, and the whale, which was hunted a few decades ago by hundreds of American vessels, has become very rare. The sea-otter, of which the party of Steller

killed seven hundred during its eight months' stay on Behring's Island, is rapidly becoming extinct, as well as the sea-lion (*Otaria stelleri*); whilst the sea-cow (*Rhytina stelleri*) was completely extirpated in the course of forty years. Thanks to the care taken by an American company which has the monopoly of hunting on Behring and Copper Islands, the sea-bear (*Otaria ursina*), which was likely to meet with the same fate, is nearly domesticated at present, and multiplies rapidly, yielding no less than twelve thousand skins per annum. The inhabitants of this region, the Chukchees (Tuski, or Chaouktoos), who number no more than 12,000 souls (according to some authorities only 5000), seem to have immigrated from the south; their racial characters make them an ethnological link between the Mongols of Central Asia and the Indians of America; they are also very nearly akin in their features and customs to the Eskimo. They are subdivided, however, into two distinct branches, with different customs and languages. Those of the interior support themselves by reindeer breeding (herds of ten thousand being not uncommon) and by hunting; whilst those of the coast live by fishing, and are very poor. All travellers who have had dealings with Chukchees speak in the highest terms of the character of the former branch, and of the fraternal feelings shown by them in their mutual relations. The Koryaks (about 5000), who occupy the southern part of this region, are nearly akin to Chukchees. They extend their migrations also to the northern part of Kamchatka. Those of the interior are reindeer proprietors and hunters, and like the Chukchees are quite independent, own no superiors, and live in federations of families. They have firmly resisted Russian conquest; and there are tribes among them which still refuse to pay the *yasak* (tribute in furs) to the Russian authorities. Their national character is described by travellers as very different from that of the settled Koryaks of the coast, who live in the utmost poverty, and have acquired vicious habits from their intercourse with European and American sailors.

The middle part of the Maritime Province is a narrow strip of land (40 to 60 miles wide) along the shores of the Sea of Okhotsk, including the basin of the Ud in the south. This area is occupied by wild mountains, 4000 to 7000 feet high, forming the eastern border of the high plateau of Eastern Siberia. Thick forests of larch clothe the mountains to nearly one-half of their height, as well as the deep valleys, where short streams discharge into the Pacific the water produced by the melting of accumulations of snow and ice (*nakipi*, *naledi*). The undulating hills of the basin of the Ud, which is a continuation to the south-west, between the Stanovoy and Bureya mountains, of the deep indentation of the Sea of Okhotsk, are covered with forests and marshes. Only Tunguses visit these inhospitable mountain wildernesses and the bays of the coast, living by hunting or fishing.

The southern part of the province includes two distinct regions. From the north-eastern extremity of the Bureya, or Little Khingan range, of which the group of the Shantar Islands is a continuation, a wide and deep depression runs south-westwards to the junction of the Amur and Usuri, and thence to the lowlands of the lower Sungari. It is for the most part less than 500 feet above sea-level.

The Amur, which takes a north-eastern course after reaching these lowlands, runs close to their eastern boundary, at the foot of the mountains of the sea-coast; whilst on its left or western bank it spreads into numberless lakes and marshes, large and small, and extensively inundates the swamps at time of flood. The area on the right banks of the Amur and Usuri, between these rivers and the sea-coast, is occupied by a very little known hilly tract consisting of several intricate systems of mountains, usually represented on maps as a single range, and known under the general name of Sikhota-alin. The summits reach the height of 5150 feet (Golaya Gora peak) and the average elevation of the few passes is about 2500 feet. There is, however, one depression in these mountains, occupied by Lake Kizi, which may have been at one time an outflow of the Amur to the sea. The Sikhota-alin mountains are covered with thick impracticable forests, through which a passage can be forced only by means of the hatchet. The lowlands and the countless islands of the Amur are covered with a grass vegetation as luxuriant as that of the forests, and present the same difficulties to the pioneer. Herbaceous plants, 7 to 10 feet high, intertwined with numberless climbing plants, cover the soil with an impenetrable thicket, and, when destroyed by fire, rapidly grow again to their former height. The flora and fauna of this region (especially in the Usuri district) exhibit a striking combination of species of warm climates with those of subarctic regions; the wild vine clings to the larch and cedar-pine, and the tiger meets the bear and the sable. The quantity of fish in the rivers is immense, and in August the wide channels of the Amur and Usuri literally swarm with the ascending salmon. The mountain-wildernesses are visited by nomadic Tunguses, while the banks of the great rivers are inhabited, besides Russians, by Golds and Orochons, both of Tungusian origin, and the lower Amur by Ghilyaks, closely allied to the Ainos of Saghalien. Manchus and Chinese are scattered here and there among the Russian population on the right bank of the Usuri.

The best part of the Maritime Province is at its southern extremity, in the valley of the Suifun river, which enters the Pacific in the Gulf of Peter the Great, and on the shores of the bays of the southern coast, where new settlements have appeared since this territory was annexed to Russia in 1860. But even here the climate is very harsh. The warm sea-current of the Kuro-sivo does not reach the coasts of Siberia, while a cold current, originating in the Sea of Okhotsk, brings its icy water and chilling fogs to the coasts of Saghalien, and flows along the Siberian shores to the eastern coast of Corea. The high mountains of the sea-coast and the monsoons of the Chinese Sea contribute to produce in the southern parts of the Maritime Province cold winters and wet summers. Accordingly, at Vladivostok (in the Gulf of Peter the Great), which has the same latitude as Marseilles, the average yearly temperature is only 39°·5 Fahr., and the harbour is frozen for nearly three months; the Amur and Usuri are frozen in November. Towards the end of summer the moist monsoons cause heavy rainfalls, which destroy the harvests and bring about such inundations that even in the two miles wide channel of the Amur the water within a few days rises more than 15 feet, and covers the lowlands to a breadth of 15 to 20 miles; the navigation also becomes dangerous for small river steamers and barges, on account of storms from the Chinese Sea. The sea-coast farther north has a continental and arctic climate. At Nikolayevsk, temperatures as low as −41°·5 Fahr. are observed in winter, and as high as 94°·6 in summer, the average yearly temperature being below zero (−0·9). At Ayan (56° 27′ N. lat.) the average temperature of the year is 25°·5 (−0°·4 in winter, and 50°·5 in summer), and at Okhotsk (59° 21′ N. lat.) it is 23° (−6° in winter, and 52°·5 in summer).

Russian settlements occur at intervals throughout the whole of the province, but, with exception of those on the banks of the Amur and Usuri, and the southern ports of the sea-coast, they are mere centres of administration. Anadyrsk on the Anadyr river, Penzhinsk and Ghizhiga at the heads of bays of the same name, Ayan on the coast of the Sea of Okhotsk, and Udskoy Ostrog on the river Ud, all have played an important part in the conquest of Siberia by Cossacks and merchants; but at present they are only small blockhouses with a few buildings around them, and the seat of local authorities; the population of none exceeds two hundred. Okhotsk, which has given its name to the sea between Kamchatka and the Siberian coast, is one of the oldest towns of Eastern Siberia, having been founded in 1649. Until the acquisition by Russia of the Manchurian sea-coast, this port, 700 miles distant from Yakutsk, poor though it is, was an object of special solicitude to the Russian Government for the maintenance of its possessions on the Pacific. It is connected by a bridle path with Yakutsk, and even in 1851–56, during the conquest of the Amur, all communication with the mouth of the Amur was by this route. It has now but 210 inhabitants. Nikolayevsk, on the left bank of the Amur, 23 miles from its mouth, was until lately the capital of the Maritime Province. Great expectations were formed regarding it when it was founded in 1851. It was provided with machine-works, foundries, and dockyards, and was proclaimed a free port. But the difficulties of navigation and of communication with the interior, and the complete failure of the governmental colonization of the Amur, made the prosperity of the new Russian port on the Pacific impossible, and the seat of government was transferred to the more central Khabarovka. At present Nikolayevsk has only 3500 inhabitants, nearly all military or officials, and a few foreign merchants trading chiefly in groceries and spirits. The port is visited every year by from twenty to twenty-five ships, importing manufactured and grocery wares to the value of about £100,000, and of wines and spirits estimated at £20,000. On the banks of the Amur, from Nikolayevsk to the mouth of the Usuri, is a chain of Russian settlements at distances not exceeding 25 miles. Their

inhabitants, free settlers from Russia, are very badly off on account of the difficulties of agriculture in this region, and from the bad selection of sites. Many have migrated to the sea-coast, whilst those who still remain are for the most part very poor, and almost every year require to be provided by Government with corn brought from Transbaikalia. Sofiysk (1000 inhabitants, of whom 700 are military) is a purely military post. Khabarovka, on a high promontory at the confluence of the Amur and Usuri, is the present capital of the Maritime Province. It has a settled population of about seven hundred, besides military and officials. A few Russian merchants carry on an active trade in furs with natives (about £20,000 a year), in silver money brought from Russia and sold to Chinese, and in spirits and groceries. The Russian settlements on the right bank of the Usuri are very like those of the lower Amur. The peasants, who have received the name of Cossacks, and have a military organization, with the exception of a few settlements on the upper Usuri, are mostly in a wretched condition, and since 1859 have been dependent for food almost every year on Government aid. A line of posts and settlements connects the villages of the Usuri with the settlements on the shores of the Gulf of Peter the Great. This wide gulf, divided into two long bays,—those of Amur and Usuri, which are connected by an inlet called the Eastern Bosphorus,—is regarded as the principal port of Russia on the Pacific, and the town on the inlet has received the name of Vladivostok ("ruler of the East"); its spacious harbour, very similar to that of Sebastopol, has been called the Golden Horn. At present Vladivostok has, however, merely the aspect of a middle-sized Russian village. One-half of its 8500 inhabitants are Chinese and Coreans, the other half being military and officials. All necessaries of life, including rye-bread biscuits, continue to be imported by sea, and every spring, before the opening of the navigation, provisions become scarce. The trade is in the hands of Chinese, who export stag-horns, sea-weed, and mushrooms to a value of about £10,000 a year, and of Germans, who import groceries and spirits (£218,500 in 1879). The entrance to the harbour is well-fortified, and the town possesses a machine-work, storehouses, and a station of the Northern Telegraph Company. Other settlements (at the Imperial, Vladimir, and Olga harbours, &c.) are developing very slowly. Altogether the Russian population of these settlements has still a provisional character, and has to overcome great difficulties before it can become independent of the interior for its means of subsistence. The total population of the Maritime Province is estimated at 20,000 Russians, (12,000 military and officials), and at about 37,000 natives; but this is certainly under the truth. The province is made up of one territory—that of the Usuri—and six circles (*okrughi*):—Nikolayevsk, Sofiysk, Petropavlovsk (Kamchatka), Okhotsk, Ghizhighinsk, and Udskoy; the territory of the Usuri is subdivided into five circles:—Usuri, Suifun, Khangka, Avvakumovo, and Suchan. (P. A. K.)

MARIUPOL, a seaport of Russia, on the northern shore of the Sea of Azoff, at the mouth of the Kalmius, in the government of Ekaterinoslav, 55 miles west of Taganrog. It is connected by a branch railway with the line between Kharkoff and Taganrog, and is situated on the highway between the latter town and the Crimea. The place is said to have been inhabited in remote times under the name of Adamakha; but the present town was built only in 1779 by Greek emigrants from the Crimea who settled on the shores of the Sea of Azoff and on the left bank of the lower Kalmius. Mariupol is the chief town of this district, the 40,000 inhabitants of which are engaged in agriculture, cattle-breeding, and fishing, and sell their produce in the town. In export trade Mariupol ranks next to Taganrog among the ports of the Sea of Azoff; but its harbour is open to the south-east and shallow, the line of 14 feet being 1½ miles from the shore, with a narrow strip, 12 to 22 feet deep, which allows larger flat-bottomed ships to approach the town, especially during south-east winds. Like all ports on this sea it is becoming more and more shallow. Mariupol is visited every year by about 150 foreign ships (about 30,000 tons) and by 700 to 860 coasting vessels (65,000 tons), mainly carrying wheat and linseed, as also skins and tallow, from the Greek district, and from the provinces of Don and Ekaterinoslav. The importance of the port may increase when the mineral riches of the district (coal close to the sea-shore, kaolin, and quartz sand) are exploited. Population, with two suburbs, Marinsk and Karasou, 9800

MARIUS, Caius (155–86 B.C.), is one of the most striking figures in Roman history. Born the son of a small farmer at Arpinum (Arpino), the birthplace also of Cicero, in 155 B.C., he worked his way up from this humble origin, in spite of the most determined opposition from the senate and the aristocracy, to the highest position in the state, was seven times consul, and was spoken of as a third Romulus and a second Camillus. He began life as a soldier, and first saw war in Spain under the great Scipio Africanus, whose good opinion he won, and so rose from the ranks to be an officer. But this was not enough to help him forward, on his return to Rome, in rising to those political offices which were invariably a stepping-stone to the highest military rank. He had, however, when about forty years of age, the good luck to marry a great lady, of patrician rank, Julia, the aunt of Julius Cæsar; and, being at the same time a popular favourite, as a man of plain and simple tastes, and a brave energetic soldier, he was in 115 B.C. elected prætor, which gave him an opportunity of still further showing his military ability in the thorough subjugation of the troublesome province of Further Spain (Spain west of the Ebro), where a good officer was specially wanted to check the marauding raids of a number of wild tribes. But it was in the war with Jugurtha, from 109 to 106 B.C., that he distinctly came to the front as the lieutenant of the consul Quintus Metellus. It would seem that his conduct towards his superior officer was not perfectly straightforward and honourable, as he tried to make the Roman traders in Africa, and through them the people of Rome, believe that the war was intentionally prolonged from corrupt motives. Under the circumstances this was comparatively easy, as political feeling was just at this time particularly bitter, and the senate was reputed, not without some good reason, to be venal and corrupt. Already Marius had achieved some important successes over Jugurtha, and had shown that he was the man to settle a tiresome guerilla war, and now, when he was a little over fifty, in 107 B.C., he was, amid great popular enthusiasm, elected consul for the first time. In the following year, in conjunction with his future political rival, Sulla, he brought the war to a triumphant issue, and passed two years in his province of Numidia, which he thoroughly subdued and annexed to Rome's dominion.

By this time Marius was generally recognized as the ablest general of the day, and in face of the great peril now beginning to threaten Rome from the north of the Alps, where an immense multitude of Cimbri and Teutones were hanging on the borders of Italy, public opinion promptly summoned him to the chief command. Two armies had been utterly destroyed in the neighbourhood of the Lake of Geneva, and it seemed as if a repetition of the disaster of Allia in 390 B.C., and the capture of Rome itself, might be not impossible. Marius, out of unpromising materials and a demoralized soldiery, organized a well-disciplined army, with which he inflicted on the invading hordes two decisive defeats, the first in 102 B.C. at Aquæ Sextiæ (Aix in the department of Bouches du Rhône, some way north of Marseilles), and the second in the following year at Vercellæ (Vercelli, about midway between Turin and Milan), the result being that for a period of some centuries Rome had nothing to fear from the northern barbarians. Deservedly indeed was Marius elected consul a fifth time, hailed as the "saviour of his country," and honoured with a triumph of unprecedented splendour.

The really glorious part of his career was now over, and the remainder of his life is associated with the worst cruelties and horrors of civil war, revolution, and proscription. The hideous strifes of Marius and Sulla have passed into a proverb. It is indeed a dreadful and monotonous story of bloodshed, but it must be carefully studied if we are to understand the nature of the political changes which had their final development in imperialism. Marius was a

plain, rough, though very able, soldier, without any of the intellectual culture which is indispensable to a statesman, and which the Gracchi, his political ancestors, possessed. As a politician he on the whole failed, though almost to the last he had the confidence of the popular party. But he unfortunately associated himself with low and vulgar demagogues, men probably more degraded than the worst of the senators and of the aristocracy, and thus, although perhaps he never quite sank to their level, he let himself be guilty of cruel and perfidious acts, which it is hard to reconcile with the character of a brave man and a hero. He was indeed appointed in 88 B.C., after a riot and partial revolution, to the command in the war in the East with Mithridates, but the triumph of Sulla and the aristocratical party almost immediately afterwards drove him as an outlaw from Rome, and he had to seek safety amid the marshes round Minturnæ (Garigliano) in Latium. The Gallic trooper sent by the local authorities to strike off the old man's head quailed, it is said, before the fire of his eye, and fled with the exclamation, "I cannot kill Caius Marius." Meantime, in the absence of Sulla, who had left Italy for the Mithridatic war, Cinna's sudden and violent revolution had put the senate at the mercy of the popular leaders, and Marius greedily caught at the opportunity of a bloody vengeance, which became in fact a reign of terror in which senators and nobles were slaughtered wholesale. He had himself elected consul, for the seventh time, in fulfilment of a prophecy given to him in early manhood. Thus, full of honours in one sense, but really hated and execrated, he closed his career, dying in the delirium of fever in 86 B.C., at seventy years of age.

Marius was not only a great and successful general, but also a great military reformer. A citizen militia was from his time exchanged for a professional soldiery, which had hitherto been as little liked by the Roman people as it was by our own ancestors. A standing army, their instincts told them, would be a ready tool of despotism; and indeed the changes of which Marius was the author paved the way for the subsequent military imperialism. The Roman soldier was henceforth a man who found his home in the camp, and who had no trade but war. A great general could hardly fail to become the first and foremost man in the state. Marius, however, himself did not attempt to overturn the oligarchy, as Cæsar afterwards did, by means of the army, but rather by such expedients as the constitution seemed to allow, though they had to be backed up by street riots and mob violence. He failed as a political reformer because the merchants and the moneyed classes, whom the more statesmanlike Gracchi tried to conciliate, feared that they would themselves be swept away by a revolution of which the mob and its leaders would be the ultimate controllers. The farmer's son, the rough blunt soldier, the saviour of his country in middle life, and its curse and pest in his old age, had a decided tinge of fanaticism and that vein of superstition which is often allied to such natures. In matters so important as canvassing for the consulship he would be guided by the counsels of an Etruscan soothsayer, and would be accompanied in his campaigns by a Syrian prophetess. The fashionable accomplishments of the day, and the new Greek culture, were wholly alien to his taste, and he was thus really disqualified for the political life of his time. When his military career was once ended, failure and disgrace became a certainty for him.

For the life of Marius our original sources are a multitude of passages in Cicero's works, Sallust's *Jugurthan War*, the epitomes of the lost books of Livy, Plutarch's *Lives*, &c. In Smith's *Biographical Dictionary* the life is given at great length, and the details stated generally with great accuracy. In Mommsen's *History of Rome*, bk. iv. chaps. 6, 7, 8, a clear picture of the whole period is presented to us; and Niebuhr's *Lectures on Roman History* (Lectures 81–86) may be consulted with great advantage.

MARIVAUX, Pierre Carlet de Chamblain de (1688–1763), novelist and dramatist, was born at Paris on the 4th February 1688. His father was a financier of Norman extraction, whose real name was Carlet, but who after the loose fashion of the period assumed the surname of Chamblain, and then, finding that others of his class had chosen the same, superadded that of Marivaux. M. Carlet de Marivaux, however, was a man of good reputation, and he received the appointment of director of the mint at Riom in Auvergne, where and at Limoges the young Pierre was brought up. It is said that he developed literary tastes early, and wrote his first play, the *Père Prudent et Equitable*, when he was only eighteen; it was not, however, published till 1712, when he was twenty-four. His chief attention in those early days was paid to novel writing, not the drama. In the three years from 1713 to 1715 he produced three novels—*Les Effets Surprenantes de la Sympathie*, *La Voiture Embourbée*, and a book which had three titles *Pharsamon*, *Les Folies Romanesques*, and *Le Don Quichotte Moderne*. All these books were in a curious strain, not in the least resembling the pieces which long afterwards were to make his reputation, but following partly the Spanish romances and partly the heroic novels of the preceding century, with a certain intermixture of the marvellous. Then Marivaux's literary ardour took a new phase. He fell under the influence of La Motte, and thought to serve the cause of that ingenious paradoxer by travestying Homer, an ignoble task, which he followed up by performing the same office in regard to Fénelon. His friendship for La Motte, however, introduced him to the *Mercure*, the chief newspaper of France, where in 1717 he produced various articles of the "Spectator" kind, which were distinguished by much keenness of observation and not a little literary skill. It was at this time that the peculiar style called Marivaudage first made its appearance in him. The year 1720 and those immediately following were very important ones for Marivaux; not only did he produce a comedy, now lost except in small part, entitled *L'Amour et la Vérité*, and another and far better one entitled *Arlequin Poli par l'Amour*, but he wrote a tragedy, *Annibal*, which was and deserved to be unsuccessful. Meanwhile his worldly affairs underwent a sudden revolution. His father had left him a comfortable subsistence, but he was persuaded by friends to risk it in the Mississippi scheme, and after vastly increasing it for a time lost all that he had. His prosperity had enabled him to marry a certain Mademoiselle Martin, of whom much good is said, and to whom he was deeply attached, but who died very shortly. His pen now became almost his sole resource. He had a connexion with both the fashionable theatres, for his *Annibal* had been played at the Comédie Française and his *Arlequin Poli* at the Comédie Italienne, where at the time a company who were extremely popular, despite their imperfect command of French, were established. He endeavoured too to turn his newspaper practice in the *Mercure* to more account by starting a weekly *Spectateur Français*, to which he was the sole contributor. But his habits were the reverse of methodical; the paper appeared at the most irregular intervals; and, though it contained some excellent work, its irregularity killed it. For nearly twenty years the theatre, and especially the Italian theatre, was Marivaux's chief support, for his pieces, though they were not ill received by the actors at the Français, were rarely successful there. The best of a very large number of plays (Marivaux's theatre numbers between thirty and forty items) were the *Surprise de l'Amour* (1722), the *Triomphe de Plutus* (1728), the *Jeu de l'Amour et du Hasard* (1730), *Les Fausses Confidences* (1737), all produced at the Italian theatre, and *Le Legs*, produced at the French. Meanwhile

he had at intervals returned to both his other lines of composition. A periodical publication called *L'Indigent Philosophe* appeared in 1727, and another called *Le Cabinet du Philosophe* in 1734, but the same causes which had proved fatal to the *Spectateur* prevented these later efforts from succeeding. In 1731 Marivaux published the first two parts of his best and greatest work, *Marianne*, a novel of a new and remarkable kind. As was usual, however, with him when he ventured on any considerable task, he was very slow with it. The eleven parts appeared in batches at intervals during a period of exactly the same number of years, and after all it was left unfinished. In 1735 another novel, the *Paysan Parvenu*, was begun, but this also was left unfinished. The year afterwards Marivaux, who was then nearly fifty years of age, was elected of the Academy. He survived for more than twenty years, and was not idle, again contributing occasionally to the *Mercure*, writing plays, "reflexions" (which were seldom of much worth), and so forth. He died on the 12th February 1763, aged seventy-five years.

The personal character of Marivaux was curious and somewhat contradictory, though not without analogies, one of the closest of which is to be found in Goldsmith. He was, however, unlike Goldsmith, at least as brilliant in conversation as with the pen. He was extremely good-natured, but fond of saying very severe things, unhesitating in his acceptance of favours (he drew a regular annuity from Helvetius), but exceedingly touchy if he thought himself in any way slighted. He was, though a great cultivator of *sensibilité*, on the whole decent and moral in his writings, and was unsparing in his criticism of the rising *Philosophes*. This last circumstance, and perhaps jealousy as well, made him a dangerous enemy in Voltaire, who lost but few opportunities of speaking disparagingly of him. Not very much is known of his life, though anecdotes of his sayings are not uncommon. He had good friends, not merely, as has been said, in the rich, generous, and amiable Helvetius, but in Madame de Tencin, in Fontenelle, and even in Madame de Pompadour, who gave him, it is said, a considerable pension, of the source of which he was ignorant. It is even asserted that annoyance at the discovery of the origin of a benefit which he thought came directly from the king hastened his death; and, though this is scarcely likely, his extreme sensitiveness is shown by many stories, one of which carries out in real life and almost to the letter Farquhar's famous *mot* as to "laughing consumedly." He had one daughter, who took the veil, the duke of Orleans, the regent's successor, furnishing her with her dowry.

We have no space here for a detailed criticism of Marivaux's extensive work. The so-called Marivaudage is the main point of importance about it, though the best of the comedies have great merits, and *Marianne* is an extremely important step in the legitimate development of the French novel,—legitimate, that is, in opposition to the brilliant but episodic productions of Le Sage. The subject-matter of Marivaux's peculiar style has been generally and with tolerable exactness described as the metaphysic of love-making. His characters, in a happy phrase of Crebillon's, not only tell each other and the reader everything they have thought, but everything that they would like to persuade themselves that they have thought. The style chosen for this is justly regarded as derived mainly from Fontenelle, and through him from the Précieuses, though there are traces of it even in La Bruyère. It abuses metaphor somewhat, and delights to turn off a metaphor itself in some unexpected and bizarre fashion. Now it is a familiar phrase which is used where dignified language would be expected; now the reverse. In the same criticism of Crebillon's which has been already quoted occurs another happy description of Marivaux's style as being "an introduction to each other of words which have never made acquaintance, and which think that they will not get on together," a phrase as happy in its imitation as in its satire of the style itself. Yet this fantastic embroidery of language has a certain charm, and suits perhaps better than any other style the somewhat unreal gallantry and *sensibilité* which it describes and exhibits. The author possessed, moreover, both thought and observation, besides considerable command of pathos. He is not, and is never any more likely to be, generally popular, but he is one of the authors in whom those who do like them are sure to take particular delight.

The best and most complete edition of Marivaux is that of 1781, 12 vols. 8vo. There is a good modern edition of the plays by E. Fournier, and another of *Marianne* and the *Paysan Parvenu* in two volumes. J. Fleury's *Marivaux et le Marivaudage* (Paris, 1881) is worth consulting by those who are interested in the subject. (G. SA.)

MARK, the traditional name of the author of the Second Gospel. The name Mark occurs in several books of the New Testament. In the Acts of the Apostles, chap. xii. mention is made of "John whose surname was Mark," to the house of whose mother, Mary, at Jerusalem, Peter went when miraculously released from prison.[1] This John Mark went with Barnabas and Paul on their missionary journey, as far as Perga in Pamphylia, and then, "departing from them, returned to Jerusalem" (Acts xii. 25; xiii. 13). His departure was afterwards the occasion of a "sharp contention" between Paul and Barnabas; the former "thought not good to take with them him who withdrew from them from Pamphylia, and went not with them to the work"; the latter "took Mark, and sailed away into Cyprus" (Acts xv. 38, 39). On the subsequent history of Mark the Acts of the Apostles are silent.

The same name Mark occurs in three Pauline epistles. (1) In Col. iv. 10 the writer enumerates Mark among his fellow-workers, mentioning also that he was a nephew (some translate "cousin") of Barnabas, and implying that he was a Jew ("of the circumcision"). He is evidently about to send him, in accordance with a previous intimation, on a special mission to the Colossians; but there is no evidence, except the statement of the Coptic subscription to the epistle, to show whether the contemplated journey took place. (2) In Philemon 24 the writer also mentions Mark as one of his fellow-workers, *i.e.*, probably in preaching the gospel during his imprisonment at Rome. (3) In 2 Tim. iv. 11 the writer gives the charge to Timothy, "Take Mark and bring him with thee, for he is useful to me for ministering." It is a plausible conjecture that this is a request that Mark might be brought back to Rome after his mission to Colossæ.

The same name also occurs in 1 Peter v. 13, "Mark, my son." This expression has sometimes been taken literally; but it is more usually understood in a metaphorical sense, as meaning that Peter had converted Mark. Those who take "Babylon" in the same passage to mean Rome necessarily infer that Mark was with Peter at Rome; a tradition to the same effect is mentioned in fragments of Clement of Alexandria, preserved in Eusebius, *H. E.*, ii. 15; vi. 14.

The preponderance of patristic and mediæval tradition is in favour of the hypothesis that the same person is designated in all these passages of the New Testament. But other hypotheses have found favour, especially among those writers of various schools who have felt a difficulty in understanding how the same person should be an intimate companion at once of St Paul and of St Peter. It has been supposed (1) that the John Mark of the Acts is the Mark of the Pauline epistles, but not the Mark of 1 Peter; (2) that the John Mark of the Acts, the Mark of the Pauline epistles, and the Mark of 1 Peter are all different; (3) that the John Mark of the Acts is the Mark of 1 Peter, but not the Mark of the Pauline epistles. Into the arguments for these several hypotheses it is unnecessary to enter here; they are of course complicated by the prior question of the authenticity and date of the books of the New Testament in which the name occurs. The most elaborate modern discussion of the question, which arrives at the conclusion that the first of the three hypotheses just mentioned is the true one, is contained in the work of Molini, whose title is given below. But, whether there was only one Mark or more than one, there is a general belief, which rests ultimately on the testimony of the presbyter (John) who is quoted by Papias (ap. Euseb., *H. E.*, iii. 39, 15), that the second canonical Gospel, or its original, is to be ascribed to the Mark who was the disciple of St Peter.[2] Of this Mark

[1] This double name, the one Jewish, the other Roman, may be compared with the double name "Saul, who is also called Paul," in succeeding chapters of the Acts; sometimes the double name, sometimes one or other of the single names, is used.

[2] Most of the arguments by which Kienlen (*Stud. u. Krit.*, 1843, pp. 423 *sq.*) endeavours to show that the Gospel is the work of the

the evangelist, as of other persons whose names are prominent in the New Testament, there is a large mass of traditional biography, in which possible fact and obvious fiction are so closely interwoven as not to be easily disentangled, and which would not be worth recording were it not for the later historical associations which have clustered round it.

Of Mark's birth and country nothing is positively known; the majority of mediæval writers state that he was a Levite; but this is probably no more than an inference from his supposed relationship to Barnabas. The Alexandrian tradition seems to have been that he was of Cyrenæan origin; and Severus, a writer of the 10th century, adds to this the statement that his father's name was Aristobulus, who, with his wife Mary, was driven from the Pentapolis to Jerusalem by an invasion of barbarians (Severus Aschimon, ap. Renaudot, *Hist. Patriarch. Alex.*, p. 2). In the apocryphal Acts of Barnabas, which profess to be written by him, he speaks of himself as having been formerly a servant of Cyrillus, the high priest of Zeus, and as having been baptized at Iconium. The presbyter John, whom Papias quotes, says distinctly that "he neither heard the Lord nor accompanied Him" (ap. Eusebius, *l.c.*); and this positive statement is fatal to the tradition, which does not appear until about two hundred and fifty years afterwards, that he was one of the seventy disciples (Epiphanius, pseudo-Origen *De recta in Deum fide*, and the author of the *Paschal Chronicle*). Various other results of the tendency to fill up blank names in the gospel history must be set aside on the same ground; it was, for example, believed that Mark was one of the disciples who "went back" because of the "hard saying" (pseudo-Hippolyt., *De LXX. Apostolis* in Cod. Barocc. ap. Migne, *Patrol. Græc.*, vol. x. 955); there was an Alexandrian tradition that he was one of the servants at the miracle of Cana of Galilee, that he was the "man bearing a pitcher of water" in whose house the last supper was prepared, and that he was also the owner of the house in which the disciples met on the evening of the resurrection (Renaudot, *l.c.*); and even in modern times there has been the conjecture that he was the "certain young man" who "fled naked" from Gethsemane, Mark xiv. 51, 52 (Olshausen).

A tradition which was widely diffused, and which is not in itself improbable, was that he afterwards preached the gospel and presided over the church at Alexandria (the earliest extant testimony is that of Eusebius, *H. E.*, ii. 16, 1; ii. 24; for the fully-developed legend of later times see Symeon Metaphrastes, *Vita S. Marci*, and Eutychius, *Origines Ecclesiæ Alexandrinæ*). There was another, though perhaps not incompatible, tradition that he preached the gospel and presided over the church at Aquileia in North Italy. The earliest testimony in favour of this tradition is the vague statement of Gregory of Nazianzus that Mark preached in Italy, but its existence in the 7th century is shown by the fact that in 629 A.D. Heraclius sent the patriarchal chair from Alexandria to Grado, to which city the patriarchate of Aquileia had been then transferred (*Chron. Patriarch. Gradens.* ap. Ughelli, *Italia Sacra*, tom. v. p. 1086; for other references to the general tradition see De Rubeis, *Monum. Eccles. Aquileien.*, c. 1; *Acta Sanctorum*, ad April. xxv.). It was through this tradition that Mark became connected with Venice, whither the patriarchate was further transferred from Grado; an early Venetian legend, which is represented in the Cappella Zen in the basilica of St Mark, antedates this connexion by picturing the evangelist as having been stranded on the Rialto, while it was still an uninhabited island, and as having had the future greatness of the city revealed to him (Danduli, *Chron.*, iv. 1, ap. Muratori, *Rer. Ital. Script.*, vol. xii. 14).

The earliest traditions appear to imply that he died a natural death (Eusebius, Jerome, and even Isidore of Seville); but the Martyrologies claim him as a martyr, though they do not agree as to the manner of his martyrdom. According to the pseudo-Hippolytus he was burned; but Symeon Metaphrastes and the *Paschal Chronicle* represent him to have been dragged over rough stones until he died. But, however that may be, his tomb appears to have been venerated at Alexandria, and there was a firm belief at Venice in the Middle Ages that his remains had been translated thither in the 9th century (the fact of the translation is denied even by Tillemont; the weakness of the evidence in support of the tradition is apparent even in Molini's vigorous defence of it, lib. ii., c. 2; the minute account which the same writer gives, lib. ii. c. 11, of the discovery of the supposed actual bones of the evangelist in 1811 A.D., is interesting). There was another though less widely accepted tradition, that the remains soon after their translation to Venice were retranslated to the abbey of Reichenau on Lake Constance; a circumstantial account of this retranslation is given in the treatise *Ex Miraculis S. Marci*, ap. Pertz, *Mon. Hist. German. Script.*, tom. v. p. 449. It may be added that the Venetians prided themselves on possessing, not only the body of St Mark, but also the autograph of his Gospel; this autograph, however, proved on examination to be only part of a 6th-century book of the Gospels, the remainder of which was published by Bianchini as the *Evangeliarium Forojuliense*; the Venetian part of this MS. was found some years ago to have been wholly destroyed by damp.

It has been at various times supposed that Mark wrote other works besides the Gospel. Several books of the New Testament have been attributed to him: viz., the Epistle to the Hebrews (Spanheim, *Op. Miscell.*, vol. ii. p. 240), the Epistle of Jude (*cf.* Holtzmann, *Die Synoptische Evangelien*, p. 373), the Apocalypse (Hitzig, *Ueber Johannes Marcus*, Zürich, 1843). The apocryphal *Acta Barnabæ* purport to have been written by him. There is a liturgy which bears his name, and which exists in two forms; the one form was found in a MS. of the 12th century in Calabria, and is, according to Renaudot, the foundation of the three liturgies of St Basil, St Gregory Nazianzen, and St Cyril; the other is that which is used by the Maronite and Jacobite Syrians. Both forms have been published by Renaudot, *Liturg. Oriental. Collect.*, vol. i. p. 127, and vol. ii. p. 176, and in Neale's *History of the Holy Eastern Church*; but neither has any substantial claim to belong to the ante-Nicene period of Christian literature.

The symbol by which Mark is designated in Christian art is usually that of a lion. Each of the "four living creatures" of Ezekiel and the Apocalypse has been attributed to each of the four evangelists in turn; Augustine and Bede think that Mark is designated by the "man"; Theophylact and others think that he is designated by the eagle; Anastasius Sinaita makes his symbol the ox; but mediæval art acquiesced in the opinion of Jerome that he was indicated by the lion. Most of the martyrologies and calendars assign April 25 as the day on which he should be commemorated; but the *Martyr. Hieron.* gives September 23, and some Greek martyrologies give January 11. This unusual variation probably arises from early differences of opinion as to whether there was one Mark or more than one.

The work of Canon Molini of Venice, *De Vita et Lipsanis S. Marci Evangelistæ*, edited, after the author's death, by S. Pieralisi, the librarian of the Barberini library, in 1864, gives full information on all that relates to the subject of the present article. (E. HA.)

MARK, GOSPEL OF. See GOSPELS.

MARKIRCH (in French, *Ste-Marie-aux-Mines*), a flourishing industrial town of Germany, in Upper Alsace, circle of Rappoltsweiler, is prettily situated in the valley of the Leber or Liepvrette, an affluent of the Rhine, near the French frontier. The once productive silver, copper, and lead mines of the neighbourhood are now no longer worked; and the present chief industries of the place are weaving and dyeing. In and about Markirch there are nearly forty wool and cotton factories, besides numerous looms in the cottages of the weavers; and these produce cloth to the annual value of £625,000. It is estimated that there are about 40,000 workpeople in the industrial district of which Markirch is the centre. The small river Leber, which intersects the town, was at one time the boundary between the German and French languages, and traces of this separation still exist. The German-speaking inhabitants on the right bank were Protestants, and subject to the counts of Rappoltstein, while the French inhabitants were Roman Catholics, and under the rule of the dukes of Lorraine. The population in 1880 was 11,824.

MARLBOROUGH, a municipal and parliamentary borough of Wiltshire, England, situated on the great high-road between London and Bath, and distant 75 miles from the former, 32 from the latter, and 13 from Devizes. It stands on the left bank of the Kennet, a tributary of the Thames, in 51° 25′ N. lat. and 1° 43′ W. long. It is an agricultural centre, and has a weekly market. In the days of its prosperity forty-two public coaches halted daily at its doors, and it had a fair trade in corn and malt; but its traffic was to a great extent diverted by the opening of the Great Western Railway, and it now carries on a very small trade in tanning, rope-making, and malting. It consists mainly of a long and broad street, terminated at one end by St Mary's church and the town-hall, and at the other by St Peter's church and the college. The municipal council consists of a mayor, four aldermen, and twelve councillors, and the borough returns one member to parlia-

Pauline and not of the Petrine Mark are used by other writers in support of the hypothesis that in its present form it is not the work of which Papias speaks.

ment. In 1881 the population of the municipal borough (area 186 acres) was 3343, and of the parliamentary borough (area 4665 acres) 5180.

The name has been a frequent matter for discussion, some declaring it to be the hill (*berg*) or fortress (*burg*) of Merlin the Briton, others the *Marl* borough, in allusion to the surrounding soil, which, however, is chalk. A great British mound exists at the south-west extremity of the town, and a castle was erected around it by William the Conqueror. This became a somewhat notable place. Henry I. kept Easter here in 1110, and Henry II. granted it to John Lackland. Henry III. held his last parliament here in 1267, and passed the "Statutes of Marleberge." Later the castle served as an occasional royal residence; it was probably dismantled during the Wars of the Roses. The town was besieged and taken during the civil wars, and a few years later (1653) was almost entirely consumed by fire. A large mansion was erected by Lord Seymour in the reign of Charles II. near the site of the castle, and this, after various vicissitudes, was in 1843 converted into "Marlborough College,"—a public school designed mainly for the education of the sons of the clergy. A large group of buildings—chapel, schools, dining hall, racket courts, &c.—soon sprung up around the original building, and the school numbered five hundred and eighty in 1882.

MARLBOROUGH, a town of the United States, in Middlesex county, Massachusetts, about 25 miles west from Boston, with stations on the Old Colony and the Fitchburg Railways. It lies in a fertile hilly district, and contains a beautiful sheet of water 160 acres in extent, known as Williams Lake. Shoemaking is the staple industry, some of the factories in the department rivalling the largest in the world. There is a good public library; and three weekly newspapers are published in the town. The population increased from 8474 in 1870 to 10,126 in 1880. Marlborough, colonized by settlers from Sudbury in 1655, and incorporated in 1661, occupies the site of the Christian Indian village of Okommakamesitt.

MARLBOROUGH, JOHN CHURCHILL, DUKE OF (1650–1722). In the small manor house of Ashe, situated in the parish of Musbury in Devonshire, but hardly a stone's throw beyond the parish of Axminster, John Churchill the first duke of Marlborough was born 24th of June 1650. Arabella Churchill, his eldest sister, and the mother of the duke of Berwick, was born in the same house on the 28th of February 1648. They were the children of Winston Churchill of Glanville Wotton in Dorset and Elizabeth the fourth daughter of Sir John Drake, who after the close of the civil war received his son-in-law into his own house. For a year or two after the Restoration John Churchill went to St Paul's school, and there is a tradition that during this period he showed the bent of his taste by reading and re-reading Vegetius *De Re Militari*. When fifteen years old he obtained a place in the household of the duke of York, and about the same time his sister Arabella became maid of honour to the duchess, two events which contributed greatly to the advancement of the Churchills. Next year, in 1666, he received, through the influence of his master, a commission in the guards, and left England for service at Tangiers. Such fighting as was waged with the Moors did not accord with his feelings, and he soon returned to his own country. For a few years afterwards Churchill remained in attendance at the court, and it was during this period that the natural carefulness of his disposition was shown by his investing in an annuity a present of £5000 given him by a court beauty. In 1672, when England to her shame sent six thousand troops to aid Louis XIV. in his attempt to subdue the Dutch, Churchill formed one of the company, and soon attracted the attention of Turenne, by whose profound military genius the whole army was directed. At the siege of Nimeguen Churchill acquitted himself with such success that the French commander predicted his ultimate rise to distinction. When Maestricht was besieged he saved the life of the duke of Monmouth, and received the thanks of Louis XIV. for his services. Early in 1678 he was married to Sarah Jennings, the favourite attendant on the Princess Anne, the younger daughter of the duke of York. Her father Richard Jennings, a Hertfordshire squire, had twenty-two brothers and sisters; one of the latter married a London tradesman called Hill, and their daughter Abigail Hill afterwards succeeded her cousin the duchess of Marlborough as favourite to Queen Anne. Sarah Jennings had as little money as her husband, but this deficiency was more than compensated for by an abundance of energy and ambition.

On the accession of James II. the Churchills received a great increase in fortune. Colonel Churchill had been created a Scotch peer in 1682, and as a reward for his services in going on a special mission from the new monarch to Louis XIV. he was advanced to the English peerage under the title of Baron Churchill of Sandridge in Hertfordshire, the village in which the Jennings's property was situated. A step in the army was at the same time conferred upon him, and when the duke of Monmouth attempted his ill-fated enterprise in the western counties the second position in command was bestowed on Lord Churchill. Through his vigilance and energy victory declared itself on the king's side. After the death of Monmouth he withdrew as far as possible from the administration of public business. Whilst on his embassy to the French court he had declared with emphasis that if the king of England should change the religion of the state he should at once leave his service, and it was not long before the design of James became apparent to the world. Churchill was one of the first to send overtures of obedience to the prince of Orange. Although he continued in a high position under James, and drew the emoluments of his places, he promised William of Orange to use every exertion to bring over the troops to his side. James had been warned against putting any trust in the loyalty of the man on whom he had showered so many favours, but the warnings were in vain, and on the landing of the Dutch prince at Brixham Churchill was sent against him with five thousand men. When the royal army had advanced to the downs of Wiltshire and a battle seemed imminent, James was disconcerted by learning that in the dead of night his general had stolen away like a thief into the opposite camp. For this timely act of treachery Churchill received another advancement in the peerage. He had now become the earl of Marlborough and a member of the privy council, a mark of royal favour which during this and the next reign was more than an unmeaning honour. William felt, however, that he could not place implicit reliance in his friend's integrity; and, with a clear sense of the manner in which Marlborough's talents might be employed without any detriment to the stability of his throne, he sent him with the army into the Netherlands and into Ireland. For some time there was no open avowal of any distrust in Marlborough's loyalty, but in May 1692 the world was astonished at the news that he had been thrown into the Tower on an accusation of treason. Though the evidence which could be brought against him was slight, and he was soon set at liberty, there is no doubt that Marlborough was in close relations with the exiled king at St Germains, and that he even went so far as to disclose to his late master the intention of the English to attack the town of Brest. The talents of the statesmen of this reign were chiefly displayed in their attempts to convince both the exiled and the reigning king of England of their attachment to his fortunes. The sin of Marlborough lay in the fact that he had been favoured above his fellows by each in turn, and that he betrayed both alike apparently without scruple or without shame. Once again during the Fenwick plot he was charged with treason, but William, knowing that if he

pushed Marlborough and his friends to extremities there were no other statesmen on whom he could rely, contented himself with ignoring the confessions of Sir John Fenwick, and with executing that conspirator himself. Not long afterwards the forgiven traitor was made governor to the young duke of Gloucester, the only one of Anne's numerous children who gave promise of attaining to manhood. During the last years of William's reign Marlborough once more was placed in positions of responsibility. His daughters were married into the most prominent families of the land: the eldest became the wife of the eldest son of Lord Godolphin; the second, the loveliest woman at the court, with her father's tact and temper and her mother's beauty, married the only son of Lord Sunderland. Higher honours were in store for his family, and they came on the accession of Queen Anne in March 1702. She had not been more than three days upon the throne before the knighthood of the Garter was conferred upon Marlborough. He was made captain-general of the English troops both at home and abroad, and master-general of the ordnance. The new queen did not forget the life-long service of his wife; three positions at the court by which she was enabled to continue by the side of the sovereign as closely as she had lived with the princess were united in her person. The queen showed her devotion to her friend by another signal mark of favour. The rangership of Windsor Park was granted her for life, with the especial object of enabling Lady Marlborough to live in the Great Lodge. These were the opening days of many years of fame and power. A week or two after the death of William it was agreed by the three great powers, England, Holland, and Austria, which formed the grand alliance, that war should be declared against France on the same day, and on May 4, 1702, the declaration was made by the three countries. Marlborough was made commander-in-chief of the united armies of England and Holland, but throughout the war his plans were impeded by the jealousy of the commanders who were nominally his inferiors, and by the opposite aims of the various countries that were striving to break the power of France. He himself wished to penetrate into the French lines; the anxiety of the Dutch was for the maintenance of their frontier and for an augmentation of their territory; the desire of the Austrian emperor was to ensure his son's rule over Spain. To secure concerted action by these different powers taxed all the diplomacy of Marlborough, but he succeeded for the most part in his desires. In the first year of the campaign it was shown that the armies of the French were not invincible. Several fortresses which Louis XIV. had seized upon surrendered themselves to the allies. Kaiserswerth on the Rhine and Venloo on the Meuse soon passed from the hands of the French to the English. The prosperous commercial town of Liége with its commanding citadel quickly capitulated. The successes of Marlborough caused much rejoicing in his own country, and for these brilliant exploits he was raised to the highest rank in the peerage, and rewarded with a handsome annuity. In the spring of the following year a crushing blow fell upon the duke and duchess. Their eldest and only surviving son, the marquis of Blandford, was seized whilst at King's College, Cambridge (under the care of Hare, afterwards bishop of Chichester), with the small-pox, and died on the 20th February 1703, in his seventeenth year. If the character of the youth which is given by Cole, the Cambridge antiquary, can be accepted as true, and Cole was not likely to be prejudiced in favour of the family of Churchill, his talents had already justified the prediction that he would rise to the highest position in the state.

The result of the campaign of 1703 inspired the French king with fresh hopes of ultimate victory. The dashing plans of Marlborough were frustrated by the opposition of his Dutch colleagues. When he wished to invade the French territory they urged him to besiege Bonn, and he was compelled to accede to their wishes. After this digression from his first purpose he returned to his original plan of attacking Antwerp; but, in consequence of the incapacity of the Dutch leaders, the generals (Villeroi and Boufflers) of the French army surprised the Dutch division and inflicted on it a loss of many thousands of men. Marlborough was forced to abandon his enterprise, and all the compensation which he received was the capture of the insignificant forts of Huy and Limburg. After a year of comparative failure for the allies, Louis XIV. was emboldened to enter upon an offensive movement against Austria; and Marlborough, smarting under the misadventures of 1703, and conscious that the war could only be brought to an end by more decisive measures, was eager to meet him. A magnificent army was sent by the French king under the command of Marshal Tallard, with instructions to strike a blow at Vienna itself. Marlborough divined the intention of the expedition, and, without communicating his intentions to his colleagues, led his troops into Bavaria. The two armies (that under Marlborough and Prince Eugène numbering more than fifty thousand men, whilst Tallard's forces were nearly ten thousand stronger) met in battle array near the village of Blenheim. The French commander made the mistake of supposing that the enemy's attack would be directed against his position in the village, and he concentrated an excessive number of his troops at that point. The early part of the fight was in favour of the French. Three times were the troops led by Prince Eugène driven back in confusion; Marlborough's cavalry failed on their first attack in breaking the line of the enemy. But in the end the victory of the allies was conclusive. Nearly thirty thousand of the French and Bavarians were killed and wounded, and in Blenheim alone ten thousand were made prisoners. Never was a victory more eagerly welcomed than this, and never was a conquering leader more rewarded than Marlborough. On his return to his own country he was received with enthusiasm on all sides. Poets and prose writers were employed to do him honour, and the lines of Addison comparing the English commander to the angel who passed over "pale Britannia" in the storm of 1703 have been famous for nearly two centuries. The manor of Woodstock, which was transferred by Act of Parliament from the crown to the duke, was a reward more after his own heart. The gift even in that form was a noble one, but the queen heightened it by instructing Sir John Vanbrugh to build a palace in the park at the royal expense, and; although the works subsequently caused much anxiety to the duke and duchess, £240,000 of public money was spent on the buildings.

The following year was not marked by any stirring incident. Marlborough was hampered by tedious formalities at the Hague and by jealousies at the German courts. The armies of the French were again brought up to their full standard, but the generals of Louis were instructed to entrench themselves behind earthworks and to act on the defensive. In the darkness of a July night these lines were broken through, and the French were forced to take shelter under the walls of Louvain. Marlborough urged an attack upon them in their new position, but his passionate arguments were spent in vain, and when 1705 had passed away the forces of the French king had suffered no diminution. This immunity from disaster tempted Villeroi in the next spring into meeting the allied forces in an open fight, but his assurance proved his ruin. The battle of Ramillies (23d May 1706) ended in the total rout of the French, and caused the transference of nearly

the whole of Brabant and Flanders to the allies. Five days afterwards the victor entered Brussels in state, and the inhabitants acknowledged the rule of the archduke. Antwerp and Ostend surrendered themselves with slight loss. Menin held out until three thousand of the soldiers of the allies were laid low around its walls, but Dendermonde, which Louis had forty years previously besieged in vain, quickly gave itself up to the resistless Marlborough. Again a year of activity and triumph was succeeded by a period of languor and depression. During the whole of 1707 fortune inclined to the other side, with the result that early in the next year Ghent and Bruges returned to the allegiance of the French, and Marlborough, fearing that their example might be followed by the other cities, advanced with his whole army towards Oudenarde. Had the counsels of Vendome, one of the ablest of the French generals, prevailed, the fight might have had a different issue, but his suggestions were disregarded by the duke of Burgundy, the grandson of Louis, and the battle, like its predecessor, ended in their defeat. After this victory Marlborough, ever anxious for decisive measures, wished to advance on Paris, but he was overruled. The allied army invested the town of Lille, on the fortifications of which Vauban had expended an immensity of thought; and after a struggle of nearly four months, and the loss of thirty thousand men, the citadel surrendered. By the end of the year Brabant was again subject to the rule of the allies. The suffering in France at this time weighed so heavily upon the people that its proud king humbled himself to sue for peace. Each of the allies in turn did he supplicate, and his minister endeavoured by promises of large sums of money to obtain the support of Marlborough to his proposals. These attempts were in vain, and when the winter passed away a French army of one hundred and ten thousand, under the command of Villars, took the field. On the 3d of August 1709 Tournay capitulated, and the two leaders, Marlborough and Eugène, led their forces to Mons, in spite of the attempt of Villars to prevent them. For the last time during the protracted war the two armies met in fair fight at Malplaquet, 11th September 1709, where the French leader had strengthened his position by extensive earthworks. The fight was long and doubtful, and, although the French ultimately retreated under the direction of Boufflers, for Villars had been wounded on the knee, it was in good order, and their losses were less than those of their opponents. The campaign lasted for a year or two after this indecisive contest, but it was not signalized by any such "glorious victory" as Blenheim. All that the English could plume themselves on was the acquisition of a few such fortresses as Douai and Bethune, and all that the French had to fear was the gradual tightening of the enemy's chain until it reached the walls of Paris. The energies of the French were concentrated in the construction of fresh lines of defence, until their commander boasted that his position was impregnable. In this way the war dragged on until the conclusion of the peace of Utrecht.

All that Marlborough had effected on the battlefield during these years of war had not prevented his position from being undermined by party intrigues at home. In the early part of Queen Anne's reign his political friends were to be found among the Tories, and the ministry was chiefly composed of members of that party. After a year or two, however, the more ardent Tories withdrew, and two younger adherents of the same cause, Harley and St John (both of whom were at present content to conceal their animosity to Marlborough), were introduced into the ministry. The duchess, partly through the influence of her son-in-law, the earl of Sunderland, and partly through the opposition of the Tories to the French war, had gone over to the Whig cause, and she pressed her views on the sovereign with more vehemence than discretion. She had obtained for her indigent cousin, Abigail Hill, a small position at court, and the poor relation very soon began to injure the benefactor who had befriended her. With Hill's assistance Harley and St John widened the breach with the queen which was commenced by the imperious manner of the duchess. The love of the two friends changed into hate, and no opportunity for humiliating the family of Marlborough was allowed to pass away neglected. Sunderland and Godolphin were the first to fall (July–August 1710); a few months later the duchess was dismissed from her offices; and, although Marlborough himself was permitted to continue in his position a short time longer, his fall was only delayed until the last day of 1711. Life in England had become so unpleasant that he went to the Continent, and he remained abroad until the death of Anne (1st August 1714). Then he once more returned to the shores of England and resumed his old military posts, but he took little part in public affairs. Even if he had wished to regain his commanding position in the country, ill-health would have prevented him from obtaining his desires: Johnson, indeed, says, in the *Vanity of Human Wishes*, that "the streams of dotage" flowed from his eyes; but it is not desirable to examine too critically the assertions of a poem which relied for its success upon the strength of its comparisons. It is certain that at the time of his death he was able to understand the remarks of others and to express his own wishes. At four o'clock on the morning of the 16th June 1722, he died at Cranbourn Lodge near Windsor. His remains were at first deposited in Westminster Abbey, in the vault at the east end of King Henry VII.'s chapel, but they now rest at Blenheim.

His widow, to whom must be assigned a considerable share both in his rise and in his fall, survived till October 1744. Those years were spent in bitter animosity with many within and without her own family. Left by her husband with the command of boundless wealth, she used it for the vindication of his memory and for the justification of her own resentment. Two of the leading opponents of the ministry, Chesterfield and Pitt, were especially honoured by her attentions. To Pitt she left ten thousand pounds, to the other statesman twice that sum and a reversionary interest in her landed property at Wimbledon. Whilst a widow, she received numerous offers of marriage from many titled suitors. She refused them all: from her marriage to her death her heart had no other inmate than the man as whose wife she had become almost a rival to royalty.

Marlborough obtained his first start in life through a handsome pension, and his rapid rise to the highest position in the state was due to his singular tact and to his skill in the management of men. In an age remarkable for grace of manner and for adroitness of compliment, his courteous demeanour and the art with which he refused or granted a favour extorted the admiration of every one with whom he came in contact. Through his consideration for the welfare of his soldiers he held together for years an army drawn from every nation in Christendom. His talents may not have been profound (he possessed "an excellent plain understanding and sound judgment" is the opinion of Lord Chesterfield); but they were such as Englishmen love. Alike in planning and in executing, he took infinite pains in all points of detail. Nothing escaped his observation, and in the hottest moment of the fight the coolness of his intellect shone conspicuous. His enemies indeed affected to attribute his uniform success in the field to fortune, and they magnified his love of money by drawing up balance sheets which included every penny which he had received, but omitted the pounds which he had spent in the cause he had sincerely at heart. All that can be

alleged in excuse of his attempt to serve two masters, the king whom he had deserted and the king who had received him into favour, is that not one of his associates was without sin in this respect.

The books on Marlborough are very numerous. Under his name in the catalogue of the British Museum there are 121 entries, and 32 under that of his wife. The chief works are Lediard's, Coxe's, and Alison's *Lives*; a French memoir in 3 volumes, 1808; Marlborough's *Letters and Despatches*, edited by Sir George Murray (5 volumes); and Mrs Creighton's interesting summary. The descriptions in Mr John Hill Burton's *Reign of Queen Anne* of the battle scenes of Marlborough are from personal observation. A good account of his birthplace and country will be found in Pulman's *Book of the Axe District*; and for the home of the duchess the reader can refer to Mr Cussan's *History of Hertfordshire*. Long after the death of the duke there were many pamphlets written on the conduct of his wife from her appearance at court; but they relate to matters of little interest at the present time. (W. P. C.)

MARLOW, Great, a parliamentary borough of Buckinghamshire, England, is finely situated on the Thames, and on a branch of the Great Western Railway, 37 miles west of London and 25 south-east of Oxford. It consists principally of two streets which cross each other at right angles. The church of All Saints, in the Later English style, erected in 1835, and lately extensively restored, possesses a number of brasses. The former bluecoat school has been reorganized under the endowed schools commission as a grammar school. The town has paper-mills, a brewery, and manufactures of lace and embroidery. It is also a favourite resort for boating and fishing. Marlow, anciently *Merlaw*, is a very ancient manor, and for some time after William the Conqueror it was in the possession of the crown. It returned members to parliament from the 28th of Edward I. till the 2d of Edward II., and the privilege was again restored in the 21st of James I.; since 1868 it has returned but one member. The borough includes Great and Little Marlow, Medmenham, and Bisham in Berkshire, which is united with Great Marlow by a suspension bridge, erected in 1835, at a cost of £20,000. The population of the borough, which has an area of 14,514 acres, 2424 being in the county of Berks, was 6627 in 1871 and 6779 in 1881.

MARLOWE, Christopher (1564–1593), the father of English tragedy and the creator of English blank verse, was born at Canterbury in February 1564, and christened on the 26th of that month. John Marlowe, his father, is said, on authority which satisfied the best editor of the poet, to have been a shoemaker by trade; it is supposed also that he was clerk of his parish, and survived his illustrious son for upwards of eleven years. The boy was educated at the King's School, Canterbury; matriculated as pensioner of Benet College, Cambridge, March 17, 1581; took the degree of bachelor of arts in 1583, and that of master of arts four years later. Before this date he had produced the first tragedy worthy of that name in our language, and called into existence that highest and most difficult of all its other than lyrical forms of verse, which alone has proved worthy of acceptance among his countrymen as the fit and adequate instrument of tragic drama. At some uncertain date of his early life he is supposed to have been an actor, and said to have broken his leg in the practice of his profession. But for this and many other traditions of his career and conversation there is no better evidence than that of a religious libeller. His first tragedy of *Tamburlaine the Great*, in two parts, was successively followed by *Doctor Faustus*, *The Jew of Malta*, *Edward the Second*, and *The Massacre at Paris*. The tragedy of *Dido, Queen of Carthage*, was probably completed for the stage after his death by Thomas Nash, the worthiest English precursor of Swift in vivid, pure, and passionate prose, embodying the most terrible and splendid qualities of a social and personal satirist; a man gifted also with some fair faculty of elegiac and even lyric verse, but in no wise qualified to put on the buskin left behind him by the "famous gracer of tragedians," as Marlowe had already been designated by their common friend Greene from among the worthiest of his fellows.

The only authentic record concerning the death of Marlowe is an entry "in the burial-register of the parish church of St Nicholas," Deptford: "Christopher Marlowe, slain by Francis Archer, June 1, 1593." Two Puritan scribblers have left two inconsistent reports as to the circumstances of this manslaughter. On the more respectable authority of Francis Meres the critic (1598) we are told that Marlowe was "stabbed to death" by a "servingman" of bad character, "a rival of his in his lewd love." The one thing unhappily certain is that one of the greatest among English poets died of a wound received in a brawl (stabbed in the head, according to one account, with his own dagger) at the untimely age of twenty-nine years and three months. Like Sir Walter Raleigh and a few less memorable men of the same generation, he was attacked in his own time not merely as a freethinker, but as a propagandist or apostle of atheism; nor was the irregularity of his life thought worthier of animadversion than the uncertainty of his livelihood. The informer whose name has survived as that of his most venomous assailant was duly hanged the year after Marlowe's death; and the list of his charges, first published by Ritson, is hardly a document which can commend itself to any man's confidence as plausibly or even possibly accurate in all its detailed report of the violent and offensive nonsense attributed to the freethinking poet in common conversation "concerning his damnable opinions."

The majestic and exquisite excellence of various lines and passages in Marlowe's first play must be admitted to relieve, if it cannot be allowed to redeem, the stormy monotony of Titanic truculence which blusters like a simoom through the noisy course of its ten fierce acts. With many and heavy faults, there is something of genuine greatness in *Tamburlaine the Great*; and for two grave reasons it must always be remembered with distinction and mentioned with honour. It is the first poem ever written in English blank verse, as distinguished from mere rhymeless decasyllabics; and it contains one of the noblest passages, perhaps indeed the noblest in the literature of the world, ever written by one of the greatest masters of poetry in loving praise of the glorious delights and sublime submission to the everlasting limits of his art. In its highest and most distinctive qualities, in unfaltering and infallible command of the right note of music and the proper tone of colour for the finest touches of poetic execution, no poet of the most elaborate modern school, working at ease upon every consummate resource of luxurious learning and leisurely refinement, has ever excelled the best and most representative work of a man who had literally no models before him, and probably or evidently was often if not always compelled to write against time for his living.

The just and generous judgment passed by Goethe on the *Faustus* of his English predecessor in tragic treatment of the same subject is somewhat more than sufficient to counterbalance the slighting or the sneering references to that magnificent poem which might have been expected from the ignorance of Byron or the incompetence of Hallam. And the particular note of merit observed, the special point of the praise conferred, by the great German poet should be no less sufficient to dispose of the vulgar misconception yet lingering among sciolists and pretenders to criticism, which regards a writer than whom no man was ever born with a finer or a stronger instinct for perfection of excellence in execution as a mere noble savage of letters, a rough self-taught sketcher or scribbler of crude

and rude genius, whose unhewn blocks of verse had in them some veins of rare enough metal to be quarried and polished by Shakespeare. What most impressed the author of *Faust* in the work of Marlowe was a quality the want of which in the author of *Manfred* is proof enough to consign his best work to the second or third class at most. "How greatly it is all planned!" the first requisite of all great work, and one of which the highest genius possible to a greatly gifted barbarian could by no possibility understand the nature or conceive the existence. That Goethe "had thought of translating it" is perhaps hardly less precious a tribute to its greatness than the fact that it has been actually and admirably translated by the matchless translator of Shakespeare—the son of Victor Hugo; whose labour of love may thus be said to have made another point in common, and forged as it were another link of union, between Shakespeare and the young master of Shakespeare's youth. Of all great poems in dramatic form it is perhaps the most remarkable for absolute singleness of aim and simplicity of construction; yet is it wholly free from all possible imputation of monotony or aridity. *Tamburlaine* is monotonous in the general roll and flow of its stately and sonorous verse through a noisy wilderness of perpetual bluster and slaughter; but the unity of tone and purpose in *Doctor Faustus* is not unrelieved by change of manner and variety of incident. The comic scenes, written evidently with as little of labour as of relish, are for the most part scarcely more than transcripts, thrown into the form of dialogue, from a popular prose *History of Dr Faustus*, and therefore should be set down as little to the discredit as to the credit of the poet. Few masterpieces of any age in any language can stand beside this tragic poem—it has hardly the structure of a play—for the qualities of terror and splendour, for intensity of purpose and sublimity of note. In the vision of Helen, for example, the intense perception of loveliness gives actual sublimity to the sweetness and radiance of mere beauty in the passionate and spontaneous selection of words the most choice and perfect; and in like manner the sublimity of simplicity in Marlowe's conception and expression of the agonies endured by Faustus under the immediate imminence of his doom gives the highest note of beauty, the quality of absolute fitness and propriety, to the sheer straightforwardness of speech in which his agonizing horror finds vent ever more and more terrible from the first to the last equally beautiful and fearful verse of that tremendous monologue which has no parallel in all the range of tragedy.

It is now a commonplace of criticism to observe and regret the decline of power and interest after the opening acts of *The Jew of Malta*. This decline is undeniable, though even the latter part of the play is not wanting in rough energy and a coarse kind of interest; but the first two acts would be sufficient foundation for the durable fame of a dramatic poet. In the blank verse of Milton alone, who perhaps was hardly less indebted than Shakespeare was before him to Marlowe as the first English master of word-music in its grander forms, has the glory or the melody of passages in the opening soliloquy of Barabas been possibly surpassed. The figure of the hero before it degenerates into caricature is as finely touched as the poetic execution is excellent; and the rude and rapid sketches of the minor characters show at least some vigour and vivacity of touch.

In *Edward the Second* the interest rises and the execution improves as visibly and as greatly with the course of the advancing story as they decline in *The Jew of Malta*. The scene of the king's deposition at Kenilworth is almost as much finer in tragic effect and poetic quality as it is shorter and less elaborate than the corresponding scene in Shakespeare's *King Richard II.* The terror of the death-scene undoubtedly rises into horror; but this horror is with skilful simplicity of treatment preserved from passing into disgust. In pure poetry, in sublime and splendid imagination, this tragedy is excelled by *Doctor Faustus*; in dramatic power and positive impression of natural effect it is as certainly the masterpiece of Marlowe. It was almost inevitable, in the hands of any poet but Shakespeare, that none of the characters represented should be capable of securing or even exciting any finer sympathy or more serious interest than attends on the mere evolution of successive events or the mere display of emotions (except always in the great scene of the deposition) rather animal than spiritual in their expression of rage or tenderness or suffering. The exact balance of mutual effect, the final note of scenic harmony, between ideal conception and realistic execution is not yet struck with perfect accuracy of touch and security of hand; but on this point also Marlowe has here come nearer by many degrees to Shakespeare than any of his other predecessors have ever come near to Marlowe.

Of *The Massacre at Paris* it is impossible to judge fairly from the garbled fragment of its genuine text which is all that has come down to us. To Mr Collier, among numberless other obligations, we owe the discovery of a noble passage excised in the piratical edition which gives us the only version extant of this unlucky play, and which, it must be allowed, contains nothing of quite equal value. This is obviously an occasional and polemical work, and being as it is overcharged with the anti-Catholic passion of the time has a typical quality which gives it some empirical significance and interest. That antipapal ardour is indeed the only note of unity in a rough and ragged chronicle which shambles and stumbles onward from the death of Queen Jeanne of Navarre to the murder of the last Valois. It is possible to conjecture, what it would be fruitless to affirm, that it gave a hint in the next century to Nathaniel Lee for his far superior and really admirable tragedy on the same subject, issued ninety-seven years after the death of Marlowe.

In the tragedy of *Dido, Queen of Carthage*, a servile fidelity to the text of Virgil's narrative has naturally resulted in the failure which might have been expected from an attempt at once to transcribe what is essentially inimitable and to reproduce it under the hopelessly alien conditions of dramatic adaptation. The one really noble passage in a generally feeble and incomposite piece of work is, however, uninspired by the unattainable model to which the dramatists have been only too obsequious in their subservience. It is as nearly certain as anything can be which depends chiefly upon cumulative and collateral evidence that the better part of what is best in the serious scenes of *King Henry VI.* is mainly the work of Marlowe. That he is at any rate the principal author of the second and third plays passing under that name among the works of Shakespeare, but first and imperfectly printed as *The Contention between the two Famous Houses of York and Lancaster*, can hardly be now a matter of debate among competent judges. The crucial difficulty of criticism in this matter is to determine, if indeed we should not rather say to conjecture, the authorship of the humorous scenes in prose, showing as they generally do a power of comparatively high and pure comic realism to which nothing in the acknowledged works of any pre-Shakespearean dramatist is even remotely comparable. Yet, especially in the original text of these scenes as they stand unpurified by the ultimate revision of Shakespeare or his editors, there are tones and touches which recall rather the clownish horseplay and homely ribaldry of his predecessors than anything in the lighter interludes of his very earliest

plays. We find the same sort of thing which we find in their writings, only better done than they usually do it, rather than such work as Shakespeare's a little worse done than usual. And even in the final text of the tragic or metrical scenes the highest note struck is always, with one magnificent and unquestionable exception, rather in the key of Marlowe at his best than of Shakespeare while yet in great measure his disciple.

Had every copy of Marlowe's boyish version or perversion of Ovid's *Elegies* deservedly perished in the flames to which it was judicially condemned by the sentence of a brace of prelates, it is possible that an occasional bookworm, it is certain that no poetical student, would have deplored its destruction, if its demerits could in that case have been imagined. His translation of the first book of Lucan alternately rises above the original and falls short of it,—often inferior to the Latin in point and weight of expressive rhetoric, now and then brightened by a clearer note of poetry and lifted into a higher mood of verse. Its terseness, vigour, and purity of style would in any case have been praiseworthy, but are nothing less than admirable, if not wonderful, when we consider how close the translator has on the whole (in spite of occasional slips into inaccuracy) kept himself to the most rigid limit of literal representation, phrase by phrase and often line by line. The really startling force and felicity of occasional verses are worthier of remark than the inevitable stiffness and heaviness of others, when the technical difficulty of such a task is duly taken into account.

One of the most faultless lyrics and one of the loveliest fragments in the whole range of descriptive and fanciful poetry would have secured a place for Marlowe among the memorable men of his epoch, even if his plays had perished with himself. His *Passionate Shepherd* remains ever since unrivalled in its way—a way of pure fancy and radiant melody without break or lapse. The untitled fragment, on the other hand, has been very closely rivalled, perhaps very happily imitated, but only by the greatest lyric poet of England—by Shelley alone. Marlowe's poem of *Hero and Leander*, closing with the sunrise which closes the night of the lovers' union, stands alone in its age, and far ahead of the work of any possible competitor between the death of Spenser and the dawn of Milton. In clear mastery of narrative and presentation, in melodious ease and simplicity of strength, it is not less pre-eminent than in the adorable beauty and impeccable perfection of separate lines or passages.

The place and the value of Christopher Marlowe as a leader among English poets it would be almost impossible for historical criticism to overestimate. To none of them all, perhaps, have so many of the greatest among them been so deeply and so directly indebted. Nor was ever any great writer's influence upon his fellows more utterly and unmixedly an influence for good. He first, and he alone, guided Shakespeare into the right way of work; his music, in which there is no echo of any man's before him, found its own echo in the more prolonged but hardly more exalted harmony of Milton's. He is the greatest discoverer, the most daring and inspired pioneer, in all our poetic literature. Before him there was neither genuine blank verse nor a genuine tragedy in our language. After his arrival the way was prepared, the paths were made straight, for Shakespeare. (A. C. S.)

MARLY-LE-ROI, chief place of a canton in the department of Seine-et-Oise, France, 5 miles to the north of Versailles and 3 miles to the south of St Germain-en-Laye, is, notwithstanding some fine country houses, a dull and unattractive village of 1250 inhabitants, which owes all its celebrity to the sumptuous chateau of Louis XIV. It was originally designed as a simple hermitage to which the king could occasionally retire with a few of his more intimate friends from the pomp of Versailles, but gradually it grew until it became one of the most ruinous extravagances of the Grand Monarque. The central pavilion (inhabited by the king himself) and its twelve subsidiary pavilions were intended to suggest the sun surrounded by the signs of the zodiac. Seldom visited by Louis XV., and wholly abandoned by Louis XVI., it was demolished after the Revolution, its art treasures having previously been dispersed, and all that now remains consists of a few mouldering ivy-grown walls, some traces of parterres with magnificent trees, the park, which is well stocked with game, and the forest of 8½ square miles, one of the most pleasant promenades of the neighbourhood of Paris.

Close to the Seine, half-way between Marly-le-Roi and St Germain, is the village of Port-Marly (500 inhabitants), and 1 mile farther up is the hamlet of Marly-la-Machine. Here, under Louis XIV., an immense hydraulic engine, driven by the current of the river, was erected; it raised the water to a high tower of 155 metres (508 English feet), where the aqueduct of Marly commenced (2100 English feet in length, 75 in height, with 36 arches, still well-preserved), carrying the waters of the Seine to Versailles. The first engine of Marly began to work in 1682, but it was necessary to modify it in 1803. In 1826 a steam-engine was substituted, and since 1858 an atmospheric engine has been employed.

MARMONT, Auguste Frédéric Louis Viesse de (1774–1852), duke of Ragusa, and marshal of France, one of Napoleon's earliest friends and most trusted generals, was born at Châtillon-sur-Seine, on July 20, 1774. He was the son of an ex-officer in the army, who belonged to the *petite noblesse*, and had adopted the principles of the Revolution. His love of soldiering soon showing itself, his father took him to Dijon to learn mathematics prior to entering the artillery, and there he made the acquaintance of Bonaparte, which he renewed after obtaining his commission when he served in Toulon. The acquaintance ripened into intimacy; Marmont became General Bonaparte's aide-de-camp, and accompanied him to Italy and Egypt, winning distinction and promotion as general of brigade. In 1799 he left Egypt with Bonaparte to the mercy of the English; he was present at the revolution of the 18th Brumaire, and organized the artillery for the expedition to Italy, which he commanded with great effect at Marengo. For this he was at once made general of division. In 1801 he became inspector-general of artillery, and in 1804 grand officer of the Legion of Honour. In 1805 he received the command of a corps, with which he did good service at Ulm. He was then directed to occupy Dalmatia with his army; he defeated the Russians on October 30 at Castel Nuovo, and occupied Ragusa. The next five years were the most creditable in his life; he was both military and civil governor of Dalmatia, and has still left traces there both in great public works and in the memories of the people. In 1807 he was made duke of Ragusa, and in 1809, being summoned up to the help of Napoleon, who was closely beset in the island of Lobau, earned the marshal's baton by his conduct at Wagram. In July 1810 he was hastily summoned from his palace, where he lived in Eastern luxury, to succeed Masséna in the command of the French army in the north of Spain, called the army of Portugal. The skill with which he manœuvred his army during the year he commanded it has been always acknowledged. His relief of Ciudad Rodrigo in the autumn of 1811 in spite of the presence of the English army was a great feat, and in the tactics which preceded the battle of Salamanca he had the best of it. The extension of his left on the 22d July 1812 was, however, fatal, and its result was the great defeat of Salamanca, in which Marmont was severely wounded in the right arm and side. He retired to France to recover, and was still hardly cured when in April 1813 Napoleon gave him the command of the 6th corps. With

it he served at the battles of Lützen, Bautzen, and Dresden, and throughout the great defensive campaign of 1814, until the last desperate battle before the walls of Paris, from which he drew back his forces to the commanding position of Essonne. Here he had 20,000 men in splendid condition, and was the pivot of all thoughts. Napoleon said of Essonne, "C'est là que viendront s'addresser toutes les intrigues, toutes les trahisons; aussi y ai-je placé Marmont, mon enfant élevé sous ma tente." Marmont betrayed this trust and suffered for it. On the restoration of the Bourbons he was made a peer of France, and a major-general of the royal guard, and in 1820 a knight of St Esprit and a grand officer of the order of St Louis, but he was never trusted, never popular. He was the major-general of the guard on duty in July 1830, and was ordered to put down with a strong hand any opposition to the ordinances (see FRANCE). After persevering some time he gave way, and allowed the republicans to succeed in their revolution. This defection brought more obloquy upon him, and the Duc d'Angoulême even ordered him under arrest, saying, "Will you betray us, as you betrayed him?" After this Marmont left France and wandered about the Continent for twenty years, publishing many volumes of travels, an edition of Cæsar and of Xenophon, and his *Esprit des Institutions Militaires*. Much of his time was spent upon his *Mémoires*, which are of real value for the military history of his time, though they must be read as a personal defence of himself in various junctures rather than as an unbiassed account of his times. They show Marmont, as he really was, an embittered man, who never thought his services sufficiently requited, a great artillery general indeed, but without the fire of genius which is so striking in several of his contemporaries, and above all, a man too much in love with himself and his own glory to be a true friend or a faithful servant.

For Marmont's military ability consult Napier, Jomini, and the historians of the time, particularly General Pelet. His own works are *Voyage en Hongrie*, &c., 4 vols., 1837; *Voyage en Sicile*, 1838; *Esprit des Institutions Militaires*, 1845; *César*; *Xenophon*; and *Mémoires*, 8 vols., published after his death in 1856. See also a long and careful notice by Sainte-Beuve, *Causeries du Lundi*, vol. vi.

MARMONTEL, JEAN FRANÇOIS (1723–1799), one of the most distinguished men of letters in Paris during the latter half of the 18th century, was born of poor parents in Limousin, on the 11th July 1723. After studying with the Jesuits at Mauriac, he taught in their colleges at Clermont and Toulouse; and in 1745, acting on the advice of Voltaire, he set out for Paris to try for literary honours. From 1748 to 1753 he wrote a succession of tragedies which,[1] though for the most part considered prolix and artificial by modern readers, had great success on the stage, and secured to Voltaire's new disciple a good position in literary and fashionable circles. Being now associated with Diderot and D'Alembert, he wrote for the great *Encyclopédie* a series of articles evincing considerable critical power and insight, which in their collected form, under the title *Éléments de Littérature*, still rank among the higher French classics. He also wrote several comic operas, the two best of which probably are *Sylvain* and *Zémire et Azore*. In 1758 he gained the patronage of Madame Pompadour, and was soon after appointed manager of the official journal *Le Mercure*, in which he had already commenced a series of elegant and attractive tales. These were the *Contes Moraux*, on which, according to some critics, Marmontel's literary reputation mainly rests. Their merit lies partly in the literary style, which in delicate finish frequently rivals that of his master Voltaire, but mainly in their graphic and charming pictures of French society under Louis XV.. After being elected to the French Academy, in 1763, he appears to have been ambitious to create a new literary style, exemplified notably in his dull prose-epic romance *Bélisaire*, now remarkable only on account of a chapter on religious toleration which incurred the censure of the Sorbonne and the archbishop of Paris. Marmontel retorted in *Les Incas*, by tracing the cruelties in Spanish America to the religious fanaticism of the Roman Catholic invaders.

After being appointed historiographer of France, secretary to the Academy (1783), and professor of history in the Lycée (1786), Marmontel in 1788 wrote a history of the regency, which is of little value. To compensate for this, however, he in 1795 began his *Mémoires*, the most interesting and valuable if not the greatest of his works, being a picturesque review of his whole life, a literary history of two important reigns, a great gallery of portraits extending from the venerable Massillon, whom more than half a century previously he had seen at Clermont, to the fiery Mirabeau amidst the tempestuous first years of the French Revolution. Reduced to poverty by the Revolution, Marmontel in 1792 retired from the Reign of Terror to Evreux, and soon after to a cottage near Gaillon, in the department of Eure. To that retreat we owe the *Mémoires*, and there, after a short stay in Paris when elected in 1797 to the Conseil des Anciens, he died on the 31st December 1799.

See Villenave, *Notices sur Marmontel*; Sainte-Beuve, *Causeries*, vol. iv.; Morellet, *Éloge*, 1805; *Edinburgh Review*, January 1806.

MARMORA, SEA OF. See BLACK SEA.

MARMOT. The word marmot may be considered to include animals belonging to the three following genera:—the true marmots, forming the genus *Arctomys* ("bear-mouse"), so called from the thickset, bear-like form of its members; the prairie marmots of North America, better known as the "prairie dogs" (*Cynomys*, "dog-mouse"); and the pouched marmots, or sousliks, comprising the genus *Spermophilus*, or seed-lovers, so named from the character of their food. These three genera are all closely allied to each other, and together form the subfamily *Arctomyinæ* of the great squirrel family, the *Sciuridæ*, of which the only other subfamily, the *Sciurinæ*, consists of the true squirrels (*Sciurus*) and the flying-squirrels (*Pteromys*). The members of the marmot subfamily are confined to the northern hemisphere, and in fact are almost entirely limited to the north temperate zone, in marked contrast to the genera of the subfamily *Sciurinæ*, which attain their greatest development in tropical or semi-tropical countries.

The *Arctomyinæ* agree in the possession of somewhat short, stumpy bodies, comparatively short tails (except in certain sousliks), and long and powerful claws suitable for burrowing. They all have broad, strong, and ungrooved incisors or cutting teeth, two pairs of premolars above and one below, and three pairs of true molars in each jaw. The grinding teeth are all on the whole very similar, the first upper premolar much smaller than the others, and nearly round, the next three teeth triangular in outline, and each with either two or three transverse grooves upon the crown; the last molar is rather broader and more complicated than the others, as is shown in fig. 2. The general form of the skeleton is very similar to that of the true squirrels, but the bones as a rule are stouter and heavier.

1. The following are the generic characters of *Arctomys*. External form stout and heavy, ears short, tail short and hairy, cheek-pouches rudimentary or absent. Fore feet with four well-developed toes, and a rudimentary thumb provided with a flat nail; skull (see MAMMALIA, p. 417, fig. 92) similar in general form to that of the other genera, but very much larger and heavier, the post-orbital processes

[1] *Denys le Tyran*, 1748; *Aristomène*, 1749; *Cléopâtre*, 1750; *Héraclides*, 1752; *Égyptus*, 1753.

stouter, and at right angles to the axis of the skull. Incisors broad and powerful. First upper premolar nearly as large as the second. Molar series nearly parallel, scarcely converging behind at all.

The various species of marmot, about ten in number, are all much alike in general appearance, ranging in size from about 15 to 25 inches in length, with tails from 3 to 6 inches long. The following are the species now generally recognized, though the Central-Asiatic forms are still very imperfectly known:—

*Arctomys marmotta*, Linn., southern Europe, the Alps, Pyrences, and Carpathians; *A. bobac*, Schreb., eastern Europe and Siberia; *A. himalayanus*, Hodgs., south-west Tibet; *A. hemachalanus*, Hodgs., Nepal; *A. caudatus*, Jacquemont, Cashmere; *A. dichrous*, Anderson, Afghanistan; *A. aureus*, Blanford, Turkestan; *A. monax*, Linn., eastern North America; *A. flaviventer*, Aud. and Bach, western United States; *A. pruinosus*, Gmel., north-western North America.

It will thus be seen that one species only is peculiar to Europe, and three to North America, while at least six, and perhaps more, are found in various parts of Central Asia,—one of these, *A. bobac*, occurring also as far west as Russia and eastern Germany.

Fig. 1.—Alpine Marmot (*Arctomys marmotta*). After Brehm.

The following account of the habits of the Alpine marmot, *A. marmotta*, extracted from Professor Blasius's well-known work on the mammals of Germany, applies, with but little variation, to all the members of the genus.

Marmots live high up in the snowy regions of the mountains, generally preferring exposed cliffs, whence they may have a clear view of any approaching danger, for which, while quietly basking in the sun or actively running about in search of food, a constant watch is kept. When one of them raises the cry of warning, the loud piercing whistle so well known to travellers in the Alps, they all instantly take to flight and hide themselves in holes and crannies among the rocks, often not reappearing at the entrance of their hiding-places until several hours have elapsed, and then frequently standing motionless on the look-out for a still longer period. Their food consists of the roots and leaves of various Alpine plants, which, like squirrels, they lift to their mouths with their fore paws.

For their winter quarters they make a large round burrow, with but one entrance, and ending in a sleeping-place thickly padded with hay. Here often from ten to fifteen marmots pass the winter, all lying closely packed together fast asleep until the spring. On awaking, hungry with their long fast, they remove the hay with which they stuff up the doors of their burrows, and resume their life of activity and watchfulness. The breeding season is in the early summer, when they bring forth from four to six young ones. Their flesh, although coarse and rank, is eaten by the peasants, and their fur, though of but little value, is also made use of.

2. Our second genus is *Cynomys*, containing only the well-known "prairie dogs," or more correctly "prairie marmots," of the United States. The genus may be characterized as follows. Size and form intermediate between *Arctomys* and *Spermophilus*. Ears and tail short. Cheek-pouches shallow. Fore feet with five claws, that on the thumb as large as that on the fifth toe. Skull heavily built, the post-orbital processes directed outwards. Dentition, as shown in fig. 2, remarkably heavy, the molar teeth differing from those of *Arctomys* and *Spermophilus* by having three instead of two transverse grooves on their crowns. First premolar nearly as large as the second. Molar series strongly convergent behind.

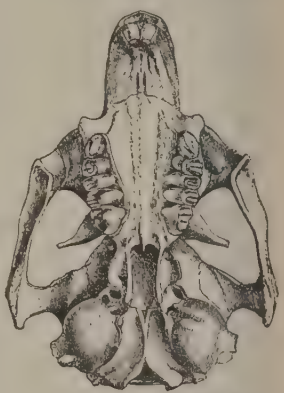

Fig. 2.—Under Side of Skull of *Cynomys ludovicianus*.

Of this genus two species have been described, very closely allied to each other, but separable by their slightly different size and coloration. The larger and better-known of the two is the eastern prairie marmot, *C. ludovicianus*, Ord., inhabiting the open prairies of the central United States, while the smaller species, *C. columbianus*, Ord., is found to the westward as far as the Rocky Mountains.

The habits of the prairie marmots have been so often described that every one is familiar with their custom of forming their burrows in groups or "towns," of sitting outside to watch intruders, and of making the peculiar barking sound from which they have derived their erroneous popular name of prairie dogs. In the burrows made by them there are commonly found three strange and, notwithstanding the earlier travellers' tales, certainly unwelcome visitors, namely, rattlesnakes, owls, and weasels, all of which at times probably prey upon the young marmots. Prairie marmots do not truly hibernate, although in the more northern and colder parts of their range they retire to their burrows during the very severest weather. They feed on grasses and roots, for whose mastication, however, their grinding teeth appear to be unnecessarily powerful.

3. The last genus to which the name marmot may be applied is that of the souslicks or pouched marmots (*Spermophilus*), of which the following are the characters Size much smaller than that of *Arctomys* or *Cynomys*, and form more slender and squirrel-like. Tail very variable, from 1 to 8 or 9 inches in length. Cheek-pouches always present. Fore feet with four well-developed toes and a rudimentary thumb, of which the claw may be either present or absent. Skull much more lightly built than that of either of the preceding genera, and the post-orbital processes slender and directed backwards. Molar series nearly parallel, as in *Arctomys*, but all much smaller and lighter; the first premolar simply rounded, never more than about one-third of the size of the second.

The members of this large genus present a far greater range of variation than is found among the true marmots, some of them, such as the European souslik, being scarcely as large as a common squirrel, almost entirely without external ears, and with the tail reduced to a mere stump, barely an inch long, while others again are more than three times this size, with long and often tufted ears and long bushy squirrel-like tails. These differences, and other corresponding cranial ones, have caused the genus

to be divided into the three following subgenera:—*Spermophilus* proper, containing thirteen or fourteen species, of small size, with rudimentary ear-conches, short stumpy tails, and comparatively large teeth; *Otospermophilus*, two species, of squirrel-like build, with large and tufted ears, and long bushy tails; and *Ictidomys*, with four species, of very slender, weasel-like form, with short ears, long but slender tails, and comparatively small teeth. The last two subgenera are confined to North America, while the range of the first is extremely similar to that of *Arctomys*, although certain species penetrate somewhat farther south in the New World, and none are found so far west in Europe. Professor Blasius gives the following details of the habits of the common European souslik (*S. citil'us*, L.).

It lives in dry treeless plains, especially on a sandy or clayey soil, and is never found either in forests or on swampy ground. It forms burrows, often 6 or 8 feet deep, in which food is stored up and the winter sleep takes place. Each burrow has but one entrance, which is closed up when winter approaches,—a second hole, however, being previously formed from the sleeping-place to just below the surface of the ground. This second hole is opened the next year, and used as the ordinary entrance, so that the number of closed up holes round a burrow gives an indication of the length of time that it has been occupied. Sousliks ordinarily feed on roots, seeds, berries, &c., but occasionally also on animal food, preying readily on eggs, small birds, and mice, the remains of these latter being often found in their burrows. They bring forth in the spring from four to eight young ones, which, if taken early, may be easily tamed. They are often eaten by the peasants, the inhabitants of the Russian steppes considering their flesh an especial delicacy. (O. T.)

MARNE, a department of the north-east of France, made up from Champagne-Pouilleuse, Rémois, Perthois, Vallage, and La Brie-Champenoise, districts formerly belonging to Champagne. Its chief town, Châlons-sur-Marne, is 92 miles in a direct line east of Paris. Bounded on the W. by Seine-et-Marne and Aisne, on the N. by Ardennes, on the E. by Meuse, on the S. by Haute-Marne and Aube, it is situated between 48° 31′ and 49° 26′ N. lat., and 3° 25′ and 5° E. long. Its greatest length from north-east to south-west is 73 miles, and the area 3159 square miles. About one half of this consists of Champagne-Pouilleuse, a monotonous and barren plain covering a bed of chalk 1300 feet in thickness. On the west and on the east it is commanded by two ranges of hills. The highest point in the department (920 feet) is in the hill district of Rheims, which rises to the south-west of the town of the same name, between the Vesle and the Marne. The lowest level (164 feet), where the Aisne leaves the department, is not far distant. To the south of the Marne the hills of Rheims are continued by the heights of La Brie (700 to 800 feet). All these belong geologically to the basin of Paris. They slope gently towards the west, but command the plain of Champagne-Pouilleuse by a steep descent on the east. On the further side of the plain are the heights of Argonne (860 feet), formed of beds of the Lower Chalk, and covered by forests; they unite the calcareous formations of Langres to the schists of Ardennes, and a continuation of them stretches southward into Perthois and the marshy Bocage. The department belongs entirely to the Seine basin, but of that river there are only 13 miles, in the south-west; it there receives the Aube, which has 10 miles within the department. The principal river is the Marne, which runs through the department for 105 miles in a great sweep concave to the south-west, passing Vitry-le-François, Châlons, Épernay, and Dormans. In its course through the department it falls from 410 to 213 feet. The principal tributaries are the Saulx (which receives the Ornain) on the right, and on the left the Blaise, which waters Vassy, the Somme Soude, and the Surmelin (with its tributary the Dhuis), whence Paris is supplied; besides the Petit Morin and the Grand Morin. Of the last three only the upper courses lie within the department. The Aisne enters the department at a point 12 miles from its source, and traverses it for 35 miles, watering Ste Menehould. Two of its affluents on the left, the Suippe and the Vesle, on which stands Rheims, have a longer course from south-east to north-west across the department.

Marne has the climate of the region of the Seine; the annual mean temperature is 50° Fahr., the rainfall about 24 inches. Of the total area about three-fourths consists of arable land, and a sixth is under forest, whilst a twenty-fifth is meadow land. Vineyards cover 63·7 square miles. The department is largely stocked with sheep (536,000, of which 133,000 are a mixed merino breed, whose wool is used in the manufacture of merinoes, flannels, and cashmeres). Cattle are estimated to number 95,260; horses, 53,000; pigs, 62,000; goats, 6000; and asses, 6000; these last are used in the narrow pathways which intersect the vineyards. About 600,000 lb of honey and 240,000 lb of wax are produced. The vineyards, though not of great extent, are of high value from the quality of their products. The manufacture of the sparkling wines of Champagne is an important industry, of which Épernay, Rheims, and Châlons are the chief centres. The yearly exportation is about 20,000,000 bottles, at the average value of half a crown a bottle. Cereals are grown in excess of the local consumption. Corn, hay, rye, barley, potatoes, and beetroot are the chief crops. Several communes supply the more valuable vegetables. In 1881 the produce of wine was more than 14½ million gallons. The principal orchard fruits are the apple, plum, and cherry. Pine woods are largely planted in Champagne-Pouilleuse. The department produces iron ore, phosphate of lime, quantities of turf, and excellent millstones and stone for building.

The chief industry is that in wool, which has brought together, in the neighbourhood of Rheims, establishments for spinning, carding, dyeing, and weaving. The materials wrought are flannels, merinoes, tartans, shawls, rugs, and fancy articles. In 1879 the aggregate length of the various stuffs measured at Rheims was 12,198 miles. This business alone occupies 30,000 operatives in the department, and produces annually nearly 800,000 pieces, valued at £18,000,000. Hosiery in woollen employs 420 looms, and in cotton 1800. Marne contains blast-furnaces, iron, copper, and bell foundries, and manufactories of agricultural implements. Besides these there are tanyards, currying and leather-dressing establishments, and glassworks, which, with sugar-works and breweries, complete the list of the most important industries. Biscuits and gingerbread are a specialty of Rheims. The chief imports are wool, coal, and colonial wares; the exports are wine, grain, live stock, stone, whiting, pit-props, and woollen stuffs. Transport is supplied by the river Marne and the canal connecting it with the Rhine and with the Aisne, and by 300 miles of railway. The population in 1881 was 421,027, an increase of 116,371 since 1801. There are five arrondissements—those of Châlons (the chef-lieu), Épernay, Rheims, Ste Menehould, and Vitry-le-François. The department belongs partly to the archbishopric of Rheims and partly to the see of Châlons. Châlons is the headquarters of the 6th army corps; to the north of the town is the great camp devoted to military exercises.

MARNE, HAUTE-, a department of eastern France, made up for the most part of districts belonging to the former province of Champagne (Bassigny, Perthois, Vallage), with smaller portions of Lorraine and Burgundy, and some fragments of Franche-Comté. It lies between 47° 35′ and 48° 40′ N. lat., and between 4° 40′ and 5° 55″ E. long., the capital, Chaumont, being 133 miles east-south-east from Paris in a direct line, and it is bounded on the N.E. by Meuse, on the E. by Vosges, on the S.E. by Haute-Saône, on the S. and S.W. by Côte d'Or, on the W. by Aube, and on the N.W. by Marne. The extreme length from north-north-west to south-south-east is 81 miles, and the area 2402 square miles. Its greatest elevation (1693 feet) is in the plateau of Langres, between the sources of the Marne and those of the Aube; the watershed between the basin of the Rhone on the south and those of the Seine and Meuse on the north, which is formed by the plateau of Langres and the Monts Faucilles, has an average height of 1500 or 1600 feet. The country descends rapidly towards the south, but in very gentle slopes northwards. To the north is Bassigny ("pays bas," as distinguished from the highlands), a district of country characterized by monotonous flats of small fertility, and generally under wood. The lowest level of the department

is 360 feet. Hydrographically Haute-Marne belongs for the most part to the basin of the Seine, the remainder to those of the Rhone and the Meuse. The principal stream is the Marne, which rises here, and has a course of 75 miles within the department. Among the more important affluents of the Marne are on the right the Rognon, and on the left the Blaise, one of the rivers of France most fully utilized for the supply of water-power. The Saulx, another tributary of the Marne on the right, also rises in Haute-Marne. Westward the department is watered by the Aube and its tributary the Aujon, both of which have their sources on the plateau of Langres. The Meuse also rises in the Monts Faucilles, and has a course of 31 miles within Haute-Marne. On the Mediterranean side the department sends to the Saône the Apance, the Amance, the Salon, and the Vingeanne. The climate is partly that of the Seine region, partly that of the Vosges, and partly that of the Rhone; the mean temperature is 51° F., nearly that of Paris; the rainfall is slightly below the average for France.

Of the total area rather more than one half is arable, about a third is under wood, a twentieth under meadow, and a fortieth is occupied by vineyards. There are 39,000 horses (extensively bred in Bassigny), 86,000 head of cattle, 170,000 sheep, 58,000 pigs, 6000 goats, 25,000 beehives, and a large quantity of all kinds of poultry. Though not very fertile, the soil is well cultivated, and in 1878 yielded 1,271,363 hectolitres of wheat, 144,348 of barley, 1,446,421 of oats, 1,177,187 of potatoes, besides meslin, rye, buckwheat, dried legumes, colza, beetroot, and hemp. Upwards of 8 million gallons of wine of ordinary quality were produced in 1881. The timber consists chiefly of oak, beech, elm, ash, maple, birch, and aspen; the orchards produce cherries, apples, pears, and prunes. The department is very rich in iron; the annual output of 300,000 tons is exceeded only by that of Meurthe-et-Moselle. Building and paving stones are quarried. The warm springs of Bourbonne-les-Bains are among the longest-known and most frequented in France. The leading industry is the metallurgical; in 1881 76,000 tons of pig iron and 85,000 of wrought iron were produced. The establishments include blast furnaces, foundries, forges, plate-rolling works, and shops for nailmaking and smith work of various descriptions. St Dizier, the place of largest population, is the chief centre of manufacture and distribution. The cutlery trade alone occupies 6000 persons in the neighbourhood of Langres. The department employs 1800 spindles in the woollen manufacture; glove-making, basket-making, brewing, tanning, and other industries are also carried on. The principal import is coal, while iron, stone, wood, and cereals are exported. The population in 1876 was 253,943, making an increase of 27,288 since 1801. There are three arrondissements (Chaumont, Langres, and Vassy), the capital being Chaumont.

MAROCCO. See Morocco.

MARONITES (Syriac, *Môrânbyê*; Arabic, *Mawârina*), an ecclesiastical community, and therefore also, according to the usage of the Christian East, a distinct political or social body, found mainly in or near the Lebanon, acknowledging the headship of the pope and the Latin standard of orthodoxy, but still retaining some peculiar privileges, including the use of a Syriac service—which few even of the priests now understand—and permission for the inferior clergy to marry. Maronite writers, trained either at Rome (in the Maronite college, founded by Gregory XIII. in 1584) or under Roman influences, have not unnaturally striven to prove that their church was always in essential accord with the Church of Rome except in ritual, but there is clear evidence that this is incorrect. The earliest references to the Maronites (beginning in the 8th century) leave no doubt that they were Monothelites, and there is contemporary evidence (William of Tyre) that they only abjured their heresies in 1182, when with their patriarch and some bishops they joined the Latin Church. Even in later times it has cost Rome much pains and money to attach them closely to herself and produce real conformity to Latin or ultimately to Tridentine orthodoxy. The origin of the Maronites and their earlier history are obscure. The name is no doubt connected with the monastery of St Maron, near the source of the Orontes, one of the chief monasteries of Syria in the 6th century;[1] the Maronites themselves (Assemani, *Bib. Or.*, i. 496 *sq.*) have much to tell of their great patriarch John Maron, or rather John of Maron, who studied at the convent of St Maron, converted the Lebanon to orthodoxy, and died 707 A.D. Much of the history of this personage is certainly fabulous.[2]

Though the Maronite college at Rome sent forth some distinguished scholars—the grammarian Amira, Gabriel Sionita, Abraham Ecchellensis, and the three Assemanis—the Maronite community never took on much Western culture. A simple warlike race, they long maintained a great measure of internal freedom under their native nobility, only paying tribute to the pasha of Tripoli; and for a time, when the princely house of Shihâb left Islam and became Maronites, they greatly outweighed the Druses in their influence in the Lebanon.[3] Since the fall, in 1840, of the Maronite emir Beshîr, who was only by outward profession a Moslem, their power has sunk. For their subsequent history see vol. vii. p. 486, and for statistics, &c., at the present time, see Lebanon.

The seat of the Maronite patriarch is at Kannôbîn (Cœnobium); the bishoprics are Aleppo, Baalbek, Jebeil, Tripoli, Ehden, Damascus, Beirût, Tyre, and Cyprus.

See in general Le Quien, *Oriens Christianus*, iii. 1–100; Nairon, *De origine, etc., Maronitarum*, Rome, 1679; Dandini's account of the mission of 1596 in the French translation with R. Simon's notes (*Voyage du Mont Lebanon*, Paris, 1685); Schnurrer, *De Ecclesia Maronitica*, 1810–1811; and Rodiger's article "Maroniten" in Herzog's *Real-Encycl.*

MAROONS. A *nègre marron* is defined by Littré as a fugitive slave who betakes himself to the woods; a similar definition of *cimarron* (apparently from *cima*, a mountain top) is given in the *Dictionary* of the Spanish Academy. The old English form of the word is *symaron* (see Hawkins's *Voyage*, sec. 68). The designation in modern English is applied almost as a proper name to the descendants of those negroes in Jamaica who at the first English occupation in the 17th century fled to the mountains. See vol. xiii. p. 550.

MAROS-VÁSÁRHELY, a royal free town of Hungary, and capital of the Transylvanian county of Maros-Torda, is situated on the Maros and on the Hungarian Eastern Railway, 50 miles north-east of Hermannstadt, in 46° 30′ N. lat., 24° 31′ E. long. It is the seat of the "royal table" court of appeal for the Transylvanian circle, of royal and circuit courts of law, of a board of works, and of offices of assay and of the Government tobacco monopoly; as also the headquarters both of the militia and regular infantry for the district. The town is well built, partly upon rising ground, and has a citadel with barracks, three churches (one large and handsome), and a college belonging to the Calvinists; Roman Catholic and Greek Orthodox churches, religious houses, and schools; a public library of 80,000 volumes, with a picture gallery and fine collection of minerals; a theatre, a hospital, and several philanthropic and industrial institutes. The trade is chiefly in timber, planks, materials for house-roofing, grain, wine, tobacco, and other products of the neighbourhood. Both weekly and special markets are held. At the end of 1880 the population amounted to 12,843 (6265 males, 6578 females), Magyars and Roumanians by nationality.

[1] The ruins of this place are described by Robinson, *Bib. Researches*, iii. 539; Renan, *Phénicie*, p. 119.

[2] The John of Maron known to Bar-Hebræus (*Chron. Eccles.*, i. 463), and placed in the 10th century, was apparently a Monophysite. That Monophysite as well as Monothelite doctrine was once current among the Maronites appears from various things in their ecclesiastical books, which they now try to explain away or reject as interpolations.

[3] See Niebuhr, *Reisebeschr.*, vol. ii.; Volney, *Voyage*; Robinson, *Researches*, ii. 506.

MAROT, CLÉMENT (1496–1544), one of the most agreeable if not one of the greatest poets of France, and a figure of all but the first importance in her literary history, was born at Cahors, the capital of the province of Quercy, some time during the winter of the year 1496–97. He was, however, not a southern by blood, at least by his father's side. That father, Jean Marot, whose more correct name appears to have been Mares, Marais, or Marets, was a Norman of the neighbourhood of Caen. He was himself a poet of considerable merit, and held the post of *escripvain* (apparently uniting the duties of poet laureate and historiographer) to Anne of Britanny. He had however, on what business or in what capacity is not known, resided in Cahors for a considerable time, and was twice married there, his second wife, whose name is not known, being the mother of Clément. The boy was "brought into France"—it is his own expression, and is not unnoteworthy as showing the strict sense in which that term was still used at the beginning of the 16th century—in 1506, and he appears to have been educated at the university of Paris, and to have then begun the study of the law. But, whereas most other poets have had to cultivate poetry against their father's will, Jean Marot took great pains to instruct his son in the fashionable forms of versemaking, which indeed required not a little instruction. It was the palmy time of the *rhétoriqueurs*, poets who combined stilted and pedantic language with an obstinate adherence to the allegorical manner of the 15th century and to the most complicated and artificial forms of the *Ballade* and the *Rondeau*. Clément himself practised with diligence this poetry (which he was to do more than any other man to overthrow), and he has left panegyrics of its coryphæus Guillaume Crétin, the unfortunate suggester of the Raminagrobis of Rabelais. Nor did he long continue even a nominal devotion to law. He became page to a certain Messire de Neuville, and this opened to him the road of court life. Besides this, his father's interest must have been not inconsiderable, and the house of Valois, which was about to hold the throne of France for the greater part of a century, was devoted to letters. As early as 1514, before the accession of Francis I., Clément presented to him his *Judgment of Minos*, and shortly afterwards he was either styled or styled himself *facteur* (poet) *de la reine* to Queen Claude. In 1519 he was attached to the suite of Marguerite d'Angoulême, the king's sister, who was for many years to be the mainstay not only of him but of almost all French men of letters. In 1524 he drew 95 livres annually from her as a pension, and he had a post in the household of her husband the Duc d'Alençon. It is certain that Marot, like most of Marguerite's literary court, and perhaps more than most of them, was greatly attracted by her gracious ways, her unfailing kindness, and her admirable intellectual accomplishments, but there is not the slightest ground for thinking that his attachment was other than platonic. Indeed the most famous passage of his poems which relates to the future queen, in which he describes her "sweet refusal with a sweeter smile," is tolerably decisive on the point. It is, however, evident that at this time either sentiment or matured critical judgment effected a great change in his style, a change which was wholly for the better. At the same time he celebrates a certain Diane, whom it has been sought to identify with Diane de Poitiers. There is nothing to support this idea and much against it, for it was an almost invariable habit of the poets of the 16th century, when the mistresses whom they celebrated were flesh and blood at all (which was not always the case), to celebrate them under pseudonyms. In the same year 1524, Marot accompanied Francis on his disastrous Italian campaign. He was wounded and taken at Pavia, but soon released, and he was back again at Paris by the beginning of 1525. His luck had, however, turned. Marguerite for intellectual reasons, and her brother for political, had hitherto favoured the double movement of *Aufklärung*, partly humanist, partly Reforming, which distinguished the beginning of the century. Formidable opposition to both forms of innovation, however, now began to be manifested, and Marot, who was at no time particularly prudent, was arrested on a charge of heresy and lodged in the Chatelet, February 1526. But this was only a foretaste of the coming trouble, and a friendly prelate, acting for Marguerite, extricated him from his durance before Easter. The imprisonment gave him occasion to write a vigorous poem on it entitled *Enfer*, which was afterwards imitated by his luckless friend Dolet. His father died about this time, and Marot seems to have been appointed to the place which Jean had latterly enjoyed, that of valet de chambre to the king. He was certainly a member of the royal household in 1528, with a stipend of 250 livres, besides which he had inherited property in Quercy. In 1530, probably, he married. Next year he was again in trouble for heresy, and was again rescued; this time the king and queen of Navarre seem to have bailed him themselves. In 1532 he published, under the title of *Adolescence Clémentine*, a title the characteristic grace of which excuses its slight savour of affectation, the first printed collection of his works, which was very popular, and was frequently reprinted with additions. Dolet's edition of 1538 is believed to be the most authoritative. Unfortunately, however, the poet's enemies were by no means discouraged by their previous ill success, and the political situation was very unfavourable to the Reforming party. In 1535 Marot was again summoned to appear on the charge of heresy, and this time he was advised or thought it best to fly. He passed through Béarn, and then made his way to Renée of Ferrara, a supporter of the French Reformers as steadfast as her aunt Marguerite, and even more efficacious, because her dominions were out of France. At Ferrara he wrote a good deal, his work there including his celebrated *Blasons* (a descriptive poem, improved upon mediæval models), which set all the verse writers of France imitating them. But the duchess Renée was not able to persuade her husband, Ercole d'Este, to share her views, and Marot had to quit the city. He then went to Venice, but before very long obtained permission to return to France. Francis himself, though a fickle and unsafe patron, was attached to him, and in 1539 gave him a house and grounds in the suburbs. It was at this time that his famous translations of the Psalms appeared. The merit of these has been sometimes denied, owing apparently to the absurd partiality which seems in the case of some critics to make it impossible for the reader to appreciate the manner of a work to the matter of which he is opposed on political or religious grounds. It is, however, considerable, and the powerful influence which the book exercised on contemporaries is not denied by any one. The great persons of the court chose different pieces, each as his or her favourite. They were sung in court and city, and they are said, with exaggeration doubtless, but still with a basis of truth, to have done more than anything else to advance the cause of the Reformation in France. Indeed the vernacular prose translations of the Scriptures were in that country of little merit or power, and the form of poetry was still preferred to prose, even for the most incongruous subjects. At the same time Marot engaged in a curious literary quarrel characteristic of the time, with a bad poet named Sagon. Half the verse writers of France ranged themselves among the Marotiques or the Sagontiques, and a great deal of versified abuse was exchanged. The victory, as far as wit was concerned, naturally rested with Marot, but his biographers are probably not fanciful in supposing that a certain amount of odium was created against him by

the squabble, and that, as in Dolet's case, his subsequent misfortunes were not altogether unconnected with a too little governed tongue and pen. Although on his last return into France he had formally abjured his errors, the publication of the Psalms gave the Sorbonne a handle, and the book was condemned by that body. In 1543 it was evident that he could not rely on the protection of Francis, who was probably too selfish in any case to have given him inconvenient help, and who, like many of his family, was disposed to compound with the church for a libertine life by ceremonial devotion and by sacrificing heretics liberally. Marot accordingly fled to Geneva; but the stars were now decidedly against him. He had, like most of his friends, been at least as much of a freethinker as of a Protestant, and, notwithstanding the immense service he had done to the cause by the publication of his Psalms, this was fatal to his reputation in the austere city of Calvin. He had again to fly, and made his way into Piedmont, where he seems to have enjoyed a sort of left-handed protection from Francis, who then held it. But the harassing effect of these constant persecutions, assisted very likely by the careless living which was but too common at the time, proved too much for him, and he died at Turin in the autumn of 1544, aged barely forty-eight.

In character Marot seems to have been a typical Frenchman of the old stamp, cheerful, good humoured, and amiable enough, but probably not very much disposed to elaborately moral life and conversation or to serious reflexion. He has sometimes been charged, though on no very definite grounds, with a want of independence of character, and his attitude towards his patrons was certainly not that of almost haughty equality which Ronsard brought in; but it is fair to remember that Marot belonged almost as much to the Middle Ages as to the Renaissance, and that in the Middle Ages men of letters naturally attached themselves as dependants to the great. Such scanty knowledge as we have of his relations with his equals is favourable to him. He certainly at one time quarrelled with Dolet, or at least wrote a violent epigram against him, for which there is no known cause. But, as Dolet quarrelled with almost every friend he ever had, and in two or three cases played them the shabbiest of tricks, the presumption is not against Marot in this matter. Whatever may have been Marot's personal weaknesses, his importance in the history of French literature is very great, and it is wont nowadays to be rather under- than over-valued. Coming immediately before a great literary reform—that of the Pléiade—Marot suffered the drawbacks of his position; he was both eclipsed and decried by the partakers in that reform. In the reaction against the Pléiade he recovered honour; but its restoration to virtual favour, a perfectly just restoration, has again unjustly depressed him. Yet Marot is in no sense one of those writers of transition who are rightly obscured by those who come after them. He himself was a reformer, and a reformer on perfectly independent lines, besides which it may be said that he carried his own reform as far as it would go. It has been said that his early work was couched in the *rhétoriqueur* style, the distinguishing characteristics of which are elaborate metre and rhyme, allegoric matter, and pedantic language. In his second stage he entirely emancipated himself from this, and became one of the easiest, least affected, and most vernacular poets of France. In these points indeed he has, with the exception of La Fontaine, no rival, and the lighter verse writers ever since have taken one or the other or both as model. In his third period he lost a little of this flowing grace and ease, but acquired something in stateliness, while he certainly lost nothing in wit. It is beyond question that Marot is the first poet who strikes readers of French as being distinctively modern. He is not so great a poet as Villon nor as some of his successors of the Pléiade, but he is much less antiquated than the first (whose works, as well as the *Roman de la Rose*, it may be well to mention that he edited) and not so elaborately artificial as the second. Indeed, if there be a fault to find with Marot, it is undoubtedly that in his gallant and successful effort to break up, supple, and liquefy the stiff forms and stiffer language of the 15th century, he made his poetry almost too vernacular and pedestrian. In his hands, and while the *style Marotique* was supreme, French poetry ran some risk of finding itself unequal to anything but graceful *vers de société*. But it is only fair to remember that for a century and more its best achievements, with rare exceptions, had been *vers de société* which were not graceful.

There is a very cheap, handsome, and useful edition of Marot by Jannet and Héricault, 4 vols., Paris, 1873; but M. Georges Guiffrey is slowly producing a costly and splendid work, containing a vast quantity of unpublished matter, which will undoubtedly be the standard. This work contains much biographical detail, which, however, as being still incomplete, is not available to modify former accounts. (G. SA.)

MARQUESAS ISLANDS, or MENDAÑA ISLANDS (French, *Les Marquises*), an archipelago of twelve islands lying between 7° 50′ and 10° 35′ S. lat., and 138° 30′ and 140° 50′ W. long. They extend over 200 miles from S.E. to N.W., and have a total area of 489 square miles. The lower or true Marquesas group consists of the islands Fatouhiva or Magdalena, Motane or San Pedro, Tahouata or Sta Christina, and Hivaoa or Dominica, the last with a coast-line of more than 60 miles. With these is often included the rocky islet of Fetohougo or Hood's, lying in mid-channel to the north of Hivaoa. The north-western or Washington group is formed of seven islands, the four largest being Roa-Poua or Adams, Houahouna or Washington, Noukahiva or Marchand (70 miles in circumference), and Hiaou. Along the centre of each island is a ridge of mountains, sometimes attaining an altitude of 3500 feet, whence rugged spurs forming deep valleys stretch towards the sea. The volcanic origin of the whole archipelago is proved by the principal rocks being of basalt, trachyte, and lava. Except on a few barren peaks the islands are clothed with verdure, and in the valleys, which are well watered with streams and brooks, the vegetation is luxuriant. The flora includes over four hundred known species, many of them identical with those belonging to the Society Islands. The vegetable products comprise bananas, bread-fruit, yams, plantains, wild cotton, bamboos, sugar-cane, cocoa-nut and dwarf palms, and several kinds of timber trees. The land fauna is, however, very poor: there are few mammals with the exception of dogs, rats, and pigs; and amphibia and insects are also generally scarce. Of twenty species of birds more than half belong to the sea, where animal life is as abundant as at other subtropical Polynesian groups.

The climate of the Marquesas, although hot and humid, is not unhealthy. During the greater part of the year moderate easterly trade winds prevail, and at the larger islands there are often both land and sea breezes; the rainy season, accompanied by variable winds, sets in at the end of November, and lasts for about six months. During this period the thermometer varies from 84° to 91° F.; in the dry season its average range is from 77° to 86°.

The inhabitants, a native Polynesian race, have in many respects a great affinity to the Tahitians, but excel them in symmetry of form. They live chiefly on bread-fruit, vegetables, and fish, almost entirely neglect agriculture, but rear hogs and fowls in great numbers. They exchange live stock, timber, vegetables, fruit, and fresh water with traders for iron utensils, firearms, gunpowder, cloth, tobacco, and brandy. They are polite in their intercourse with strangers, susceptible and courageous, but at the same time excitable, revengeful, addicted to stealing, lazy, and immoral. The efforts of missionaries, whether Protestant or Roman Catholic, have hitherto proved of little avail either in converting them to Christianity or in improving their moral and social condition. At the commencement of the present century the population exceeded 20,000, but since then petty warfare, infectious maladies, and various other causes have greatly reduced its number; and on the 31st December 1876 it reached only 5754.

In 1842 the Marquesas archipelago was formally taken possession of for France by Captain Du Petit-Thouars; and the French still maintain a nominal protectorate over the islands, with a resident and a small garrison at Noukahiva. Since 1861, however, French colonization has been virtually abandoned.

The Marquesas Islands were first discovered 21st July 1595, by Alvaro Mendaña, who, however only knew of the south-east group, to which he gave the name of Marquesas de Mendoza, in honour of the viceroy of Peru. Cook, pursuing the same track, rediscovered this group, with the addition of Fetohougo, in 1774. The north-

west islands were first sighted by Ingraham the American in 1791, and were subsequently visited by Marchand (1791) and Hergest (1792). A more extensive investigation of the archipelago was made by Kruscnstern in 1804. Of later navigators to the Marquesas the most noteworthy are Stewart (1829), Bennett (1835), and D'Urville (1838), and, since the date of the French occupation, Dumoulin, Jouan, and above all Jardin.

See C. E. Meinicke, *Die Inseln des stillen Oceans*, Leipsic, 1875–76; *Tableaux de pop., &c., des col. franç.* for 1877.

MARQUETRY. See FURNITURE.

MARQUETTE, a city and port of entry of the United States, and the county seat of Marquette county, Michigan, lies on a bluff about 25 feet above a bay of Lake Superior, and is a terminus of the Marquette, Houghton, and Ontonagon, and the Detroit, Mackinac, and Marquette Railroads. Though the population of the city was only 4690 in 1880, Marquette is a place of importance as the chief shipping port for the great iron-ore region of western Michigan (787,150 tons shipped in 1881), and contains a number of blast furnaces, foundries, machine-shops, and powder-mills, while at the same time it has a reputation as a resort for invalids and tourists. A Roman Catholic cathedral, convent, and orphan asylum are among the public buildings.

MARQUETTE, JACQUES, a Jesuit missionary and explorer, was born in 1637 at Laon in France, and died May 18, 1675, on the banks of a small stream, now known as the Marquette, which has its mouth on the eastern shore of Lake Michigan. Having joined the Society of Jesus, he sailed for Canada in 1666, spent eighteen months in the vicinity of Three Rivers, founded the mission of Sault Sainte Marie on Lake Superior in 1668, and followed the Hurons to Mackinaw in 1671. It is mainly, however, as Joliet's companion in his voyage down the Mississippi in 1673 that Marquette holds a permanent position in the history of discovery in America.

His narrative, first published in Thevenot's *Recueil de Voyages* (Paris, 1681), is printed along with other documents relating to him in Shea's *Discovery and Exploration of the Mississippi Valley* (New York, 1852).

MARQUIS, or MARQUESS, a title and rank of nobility, the second in the order of the British peerage, and therefore next to duke. The first marquis in England was Robert de Vere, the ninth earl of Oxford, who by Richard II., 1st December 1385, was created marquis of Dublin. On the 13th of October following the patent of this marquisate was recalled, Robert de Vere then having been raised to a dukedom. John de Beaufort, the second legitimate son of John of Gaunt, was created to the second marquisate as marquis of Dorset, 29th September 1397. From that period this dignity appears to have been dormant till the reign of Henry VI., when it was revived, and thenceforward it maintained its place in the British peerage. A marquis is "most honourable," and is styled "my lord marquis."

Marquis's Coronet.

His wife, who also is "most honourable," is a marchioness, and is styled "my lady marchioness." The coronet is a circlet of gold on which rest four leaves and as many large pearls, all of them of equal height and connected. The cap and lining, if worn, are the same as in the other coronets. The coronet, which in representations displays one central leaf with two pearls and two half-leaves, when without cap or lining, is shown in the annexed woodcut. The mantle of parliament is scarlet, and has three and a half doublings of ermine.

MARRIAGE, LAW OF.[1] Marriage may be defined here as the act, ceremony, or process by which the legal relationship of husband and wife is constituted. In most if not all legal systems it takes the form of a contract—the mutual assent of the parties being the prominent and indispensable feature of the ceremony. Whether it is really a contract or not, and if so to what class of contracts it belongs, are questions which have been much discussed, but into which it is not necessary to enter. While the consent of parties is universally deemed one of the conditions of a legal marriage, all the incidents of the relationship constituted by the act are absolutely fixed by law. In the United States it has been expressly decided that marriage is not a contract within the meaning of the constitutional law, which prohibits state enactments "impairing the obligation of contracts." Mr Bishop, however, in his very valuable book on *Marriage and Divorce*, suggests that a State law permitting the status of marriage to be created without the consent of both parties would not be constitutional; but that is a difficulty arising out of the peculiar relation of the States to the Union. The question whether marriage is merely a contract or more than a contract, whether a purely civil or also a religious act, belongs to a similar order of inquiries. The jurist has only to deal with marriage in so far as it creates the legal status of husband and wife. It should be added that, while marriage is generally spoken of by lawyers as a contract, its complete isolation from all other contracts is invariably recognized. Its peculiar position may be seen at once by comparing it with other contracts giving rise to continuous relationships with more or less indefinite obligations, like those of landlord and tenant, master and servant, &c. In these the parties may in general make their rights and duties what they please, the law only intervening when they are silent. In marriage every resulting right and duty is fixed by the law.[2]

*Roman Law.*—The three primitive modes of marriage were *confarreatio*, *coemptio in manum*, and *usus*, all of which had the effect of placing the woman in the "power" (*manus*) of her husband, and on the same footing as the children. The first was a religious ceremony before ten witnesses, in which an ox was sacrificed and a wheaten cake broken and divided between the spouses by the priest. *Coemptio* was a conveyance of the woman by *mancipatio*, and might be described as a fictitious sale *per æs et libram*, like that employed in emancipation and testamentary disposition and other processes. *Usus* was the acquisition of the wife by prescription, through her cohabiting with the husband for one year without having been absent from his house three continuous nights. But a true marriage might be concluded without adopting any of these modes, and they all fell into desuetude and with them the subjection of the wife to the manus. Marriage without manus was contracted by the interchange of consent, without writing or formality of any kind. By some jurists it is regarded as incomplete until consummated by delivery of the woman, and is accordingly referred to the class of *real* contracts. The restrictions as to age, relationship by consanguinity and affinity, previous marriage, &c., were in the main those which have continued to prevail in modern Europe with one important exception. The consent of the *paterfamilias* to the marriage of the children under his power was essential.

In the *Canon Law*, which is related on the one hand to the civil law, on the other to the modern matrimonial law of Europe, although marriage was not merely a contract but a sacrament, the validity of marriages by consent was nevertheless admitted. "When the natural and civil contract was formed," says Lord Stowell, "it had the full

[1] See also HUSBAND AND WIFE and DIVORCE.

[2] A full collection of juridical opinion as to the legal character of marriage is to be found in Lord Fraser's *Husband and Wife*, vol. i. chap. ii.

essence of matrimony without the intervention of a priest. It had even in that state the character of a sacrament, for it is a misapprehension to suppose that this intervention was required as a matter of necessity even for that purpose before the council of Trent."[1]

*England.*—Marriage may be the subject of an ordinary contract on which an action may be brought by either party. It is not necessary that the promise should be in writing, or that any particular time should be named. The parties were formerly inadmissible as witnesses in this action; but they are now competent to give evidence, subject to the condition that the plaintiff shall not recover "unless his or her testimony shall be corroborated by some other material evidence" (32 & 33 Vict. c. 68). The ordinary defences, *e.g.*, fraud, discharge, minority, are available in these actions, and there are also special defences arising from the nature of the contract, such as the bad character of the plaintiff, the relationship of the parties within the prohibited degrees, &c. Promises to marry are not within the meaning of "agreement made in consideration of marriage" in the statute of frauds, which requires such agreements to be in writing. Contracts in restraint of marriage, *i.e.*, whose object is to prevent a person from marrying anybody whatever, are void, as are also contracts undertaking for reward to procure a marriage between two persons. These latter are termed marriage brocage contracts.

Any man and woman are capable of marrying, subject to certain disabilities, some of which are said to be canonical as having been formerly under the cognizance of the ecclesiastical courts, others civil. The effect of a canonical disability as such was to make the marriage not void but voidable. The marriage must be set aside by regular process, and sentence pronounced during the lifetime of the parties. Natural inability at the time of the marriage to procreate children is a canonical disability. So was proximity of relationship within the prohibited degrees, which has been made an absolute avoidance of marriage by 5 & 6 Will. IV. c. 54. A pre-engagement to another person was at one time recognized as a canonical disability. Civil disabilities are (1) the fact that either party is already married and has a spouse still living;[2] (2) the fact that either party is a person of unsound mind; (3) want of full age, which for this purpose is fixed at the age of puberty as defined in the Roman law, viz., fourteen for males and twelve for females;[3] (4) proximity of relationship within the prohibited degrees, already alluded to. The statute which lawyers regard as establishing the rule on this last point is the 32 Henry VIII. c. 38 (repealed in part by 2 & 3 Edw. VI. c. 23, in whole by 1 & 2 P. and M. c. 8, but revived by 1 Eliz. c. 1, and so left as under the Act of Edward), which enacts that "no prohibition, God's law except, shall trouble or impeach any marriage without the Levitical degrees." The forbidden marriages, as more particularly specified in previous statutes, are those between persons in the ascending and descending line *in infinitum*, and those between collaterals to the third degree inclusive, according to the computation of the civil law, which reckons from one of the persons related to the common stock and so down to the other person. The prohibitions extend not only to *consanguinei* (related by blood) but to *affines* (related by marriage). A man may neither marry his sister nor his deceased wife's sister, for both are related to him in the second degree; nor his sister's daughter, nor his deceased wife's sister's daughter, for both are in the third degree; but he may marry his first cousin, for she is in the fourth degree. *Consanguinei* of either spouse are related by affinity to the other; but the *consanguinei* of the one are not necessarily related to the *consanguinei* of the other. Hence two brothers may marry two sisters, or a father and son a mother and daughter. A husband is not related to the *affines* of his wife, and so a man may marry the widow of his deceased wife's brother. The rule as to collaterals includes those related by the half blood and bastards (see Stephen's *Commentaries*, book iii. c. 2). Other disabilities previously admitted were abolished by the statute of Henry. The Act of 5 & 6 Will. IV. c. 54 enacted that "all marriages which shall hereafter be celebrated between persons within the prohibited degrees of consanguinity or affinity shall be absolutely null and void to all intents and purposes whatsoever." They had previously, as already stated, been only voidable. The Act at the same time legalized marriages within the prohibited degrees of affinity (but not consanguinity) actually celebrated before the 31st August 1835.

The celebration of marriages is now regulated wholly by statutory legislation. The most important Acts now in force are the 4 Geo. IV. c. 76 and the 6 & 7 William IV. c. 85.[4] The former regulates marriages within the Church of England, but was intended to be of universal application, Jews and Quakers only being excepted by section 31. It requires either the previous publication of banns, or a licence from the proper ecclesiastical authority. As to banns, the rule of the rubric, so far as not altered by the statute, is required to be observed. They must be published on three successive Sundays at morning service after the second lesson, in the church of the parish in which the parties dwell; the bishop may, however, authorize the publication of banns in a public chapel. Seven days' notice must be given to the clergyman of the names of the parties, their place of abode, and the time during which they have lived there. If either party is under age, the dissent of the parents or guardians expressed at the time of publication of banns renders such publication null and void. Licence in lieu of banns may only be granted by the archbishop, bishop, or other authority, for the solemnization of a marriage within the church of the parish in which one of the parties shall have resided for fifteen days before. Before a licence can be granted an oath must be taken as to the fact of residence and that the necessary consent has been obtained in the case of persons under age. The father, or lawful guardian, or mother if unmarried, or guardian appointed by the court, is each in order of substitution the proper person to consent to the marriage of a minor, and the place of any such person incapacitated mentally is taken by the lord chancellor. The absence of such consent does not, however, avoid a marriage once solemnized. But if persons wilfully intermarry (unless by special licence) in a place not being a church or public chapel, or without due publication of banns or proper licence, or before a person not in holy orders, the marriage is null and void to all purposes. Marriage must be celebrated within three months after banns or licence, and between the hours of eight and twelve in the morning.

For the relief of the great body of dissenters the Act 6 & 7 Will. IV. c. 85 was passed. It permits marriage to be solemnized in two additional ways,—viz. (1) by certificate of the superintendent registrar of a district without licence, and (2) by such certificate with licence. In the first case, notice must be given to the registrar of the district or districts within which the parties have resided for seven days previous, which notice is inscribed in a marriage notice book, open to public inspection at all reasonable times, and thereafter suspended for twenty-one days in some conspicuous place in the registrar's office. The notice must be accompanied by a declaration as to the absence of impediments, necessary consent, &c. Any person whose consent is necessary to an ecclesiastical licence may forbid the issue of a certificate, but in default of such prohibition the certificate will issue at the end of the twenty-one days. The marriage may then take place on any day within three months of the entry of notice, and in one of the following ways:—(1) in a certified place of religious worship, registered for the solemnization of marriage; in that case a registrar of the district with two witnesses must be present, and the ceremony must include a mutual declaration of assent by the parties and a disavowal of any impediment; (2) at the superintendent registrar's office, with the same

[1] Some restrictions on marriage peculiar to the canon law are noticed at the end of this article.

[2] A divorce *nisi* does not enable the parties to marry until it is made absolute.

[3] A marriage in which either of the parties is below the age of consent is, however, said to be not absolutely void; if the parties agree to continue together at the age of consent no new marriage is necessary, but either of them may disagree and avoid the marriage.

[4] A complete list of the acts regulating the solemnization of marriage or confirming marriages which through some defect might be void will be found in Phillimore's *Ecclesiastical Law*, vol. i.

declaration, but with no religious service; (3) in a church according to the usual form, the consent of the minister thereof having been previously obtained; (4) according to the usages of Jews and Quakers. The place of marriage in all cases must have been specified in the notice and certificate.

In the second case, when it is desired to proceed by licence, notice must be given to the registrar of the district in which one of the persons resides, together with a declaration that he or she has resided for fifteen days therein, that there is no impediment, and that the necessary consents if any have been obtained. The notice is not exhibited in the registrar's office, and the certificate may be obtained at the expiration of one whole day after entry, together with the licence. No registrar's licence can be granted for a marriage in church or according to the forms of the Church of England,—the ecclesiastical authorities retaining their monopoly in that respect. It is also provided that in the case of persons wilfully intermarrying in a place other than that mentioned in the notice and certificate, or without notice or certificate, &c., the marriage shall be null and void. And, as under the former Marriage Act of Geo. IV., a valid marriage between persons one of whom is under age, brought about by fraud or false oath, subjects the offending party to a forfeiture of all property that otherwise might accrue to him from the marriage, a like penalty is provided in like cases under the later Act.

It will be observed that the various rules as to consent of parents, &c., to the marriages of minors are regulations of procedure only. The absence of the necessary consent is not a disability invalidating a marriage actually solemnized.

The Act 26 Geo. II. c. 33, commonly known as Lord Hardwicke's Act, which forbids the solemnization of marriage without banns or licence, also enacts that "in no case whatsoever shall any suit or proceeding be had in any ecclesiastical court in order to compel a celebration *in facie ecclesiæ*, by reason of any contract of matrimony whatsoever whether *per verba de presenti* or *per verba de futuro*." Blackstone observes that previous to this Act "any contract made *per verba de presenti*, or in words of the present tense, and in case of cohabitation *per verba de futuro* also, was deemed valid marriage to many purposes; and the parties might be compelled in the spiritual courts to celebrate it *in facie ecclesiæ*." In his celebrated judgment in the case of Dalrymple *v.* Dalrymple, which turned on the effect of promises exchanged between the parties in Scotland, Lord Stowell laid it down "as the basis of the canon law, the known basis of the matrimonial law of Europe," that "in the irregular marriage, *i.e.*, *sponsalia per verba de presenti*, everything was presumed to be complete and consummated in substance but not in ceremony; and the ceremony was enjoined to be undergone as a matter of order. In the *sponsalia de futuro* nothing was presumed to be complete or consummated either in substance or in ceremony, but if the parties who had exchanged the promise had carnal intercourse with each other the effect was to convert the engagement into an irregular marriage." On the other hand, in the case of the Queen *v.* Millis in the House of Lords on appeal from the Irish Queen's Bench, the position of Lord Stowell was strongly criticized. Lord Lyndhurst's conclusion was that, "although a marriage contracted *per verba de presenti* was indissoluble, though it could not be released even by the mutual consent of the parties, though either of them might enforce it and compel solemnization, though it had the effect of rendering voidable a subsequent marriage solemnized *in facie ecclesiæ*, even after the cohabitation and birth of children, though it was considered to be of the essence and substance of matrimony—yet by the law of England it did not confer those rights of property or the more important right of legitimacy consequent on a marriage duly solemnized according to the rites of the church." The lords were equally divided in their decision, and the question has since been agitated not so much with reference to England, where after the Act of Geo. II. it had a merely historical interest, as to the colonies and the United States (see below), where the common law of England prevails unless changed by legislation. Dr Lushington in the case of a marriage in New South Wales declared that, when there has been a "fact of consent between two parties to become man and wife," such is "sufficient marriage to enable me to pronounce when necessary a decree of separation." In the cases noticed the promises had been exchanged before ministers of religion not technically "in holy orders," and the question has accordingly sometimes been put in the form whether, according to the common law, the intervention of a clergyman was necessary to a valid marriage.

Royal Marriages in England have been subject to special laws. The Royal Marriage Act of 1772 (12 Geo. III. c. 11), passed in consequence of the marriages of the dukes of Cumberland and Gloucester, enacted that "no descendant of his late majesty George II. (other than the issue of princesses married or who may marry into foreign families) shall be capable of contracting matrimony without the previous consent of his majesty, his heirs and successors, signified under the great seal. But in case any descendant of George II., being above twenty-five years old, shall persist to contract a marriage disapproved of by his majesty, such descendant, after giving twelve months' notice to the privy council, may contract such marriage, and the same may be duly solemnized without the consent of his majesty, &c., and shall be good except both Houses of Parliament shall declare their disapprobation thereto."

*Scotland.*—The chief point of distinction, as compared with English law, is the recognition of irregular marriages above noticed. (1) "A public or regular marriage," says Fraser, "is one celebrated, after due proclamation of banns, by a minister of religion; and it may be celebrated either in a church or in a private house, and on any day of the week at any hour of the day." The ministers of the national church at first alone could perform the ceremony; but the privilege was extended to Episcopalians by 10 Anne c. 7, and to other ministers by 4 & 5 Will. IV. c. 28. (2) A marriage may also "be constituted by declarations made by the man and the woman that they *presently* do take each other for husband and wife." These declarations "may be emitted on any day at any time and without the presence of witnesses," and either by writing or orally or by signs, and in any form which is clearly expressive of intention. Such a marriage is as effectual to all intents and purposes as a public marriage. The children of it would be legitimate; and the parties to it would have all the rights in the property of each other, given by the law of Scotland to husband and wife. (3) A promise followed by *copula* does not, according to Fraser, constitute marriage, unless followed either by solemnization *in facie ecclesiæ* or declarator. On the other hand, in Lorimer's *Handbook* it is urged that the promise and copula are mere tokens of consent recognized by the law, and that "the date of the marriage is the date of the copula." However this may be, Lord Moncreiff's opinion in the case of Brown *v.* Burns is admitted on both sides to be good law, viz., that declarator is essential to the constitution of a marriage of this kind, so that, if no such declarator be brought in the lifetime of both parties, the marriage can never be established afterwards. The *copula* is presumed to have reference to the promise, but evidence may be adduced to show that such was not the case.

By 19 & 20 Vict. c. 96, it is enacted that no *irregular* marriage shall be valid in Scotland, unless one of the parties has lived in Scotland for the twenty-one days next preceding the marriage, or has his or her usual residence there at the time.

"Habit and repute" has sometimes been spoken of as constituting marriage in the law of Scotland, but it is more correctly described as evidence from which marriage may be inferred. The repute must be the general, constant, and unvarying belief of friends and neighbours, not merely the controverted opinion of a section of them. The cohabitation must be in Scotland, but in one case proof of cohabitation in another country was allowed, as tending to throw light on the nature of the cohabitation in Scotland.

The consent of parents is not necessary to the validity of the marriage, even of minors, but marriage under the age of puberty with or without such consent is void.

*United States.*—The absence of ecclesiastical courts has suggested difficulties as to the extent to which the law of England on this subject continued to prevail after the revolution. Bishop holds it to be the universal fact running through all the cases that everywhere in the country the English decisions on marriage and divorce are referred to with the same apparent deference which is shown on other subjects to the decisions of the English common law and equity tribunals. The same author observes that "all our marriage and divorce laws, and of course all our statutes on the subject, in so far as they pertain to localities embraced within the limits of particular States, are State laws and State statutes, the national power with us not having legislative or judicial cognizance

of the matter within those localities." Some of the States have extended the ages below which marriage cannot take place. The common law of the States is assumed to be that "a contract *per verba de presenti*, or *per verba de futuro cum copula*, constitutes a complete marriage." Conditions, however, may be imposed by the various State legislatures, and as to these the rule has established itself in American jurisprudence that "a marriage good at common law is good notwithstanding the existence of any statute on the subject, unless the statute contains express words of nullity." Thus in Pennsylvania, where a statute provided that all marriages "should be solemnized before twelve witnesses," marriages not so celebrated were nevertheless held to be good. In New Hampshire justices and ministers of the gospel are authorized to solemnize marriage, and all other persons are forbidden to do so under penalties; yet a marriage by consent, as at common law, without justice or minister, has been held valid. On the other hand, under a very similar statute in Massachusetts, it was held that "parties could not solemnize their own marriage," and that a marriage by mutual agreement, not in accordance with the statute, was void. Bishop regards this as an isolated exception to the general course of the decisions. So when State legislation requires any particular form to be used the want thereof only invalidates the act if the statute expressly so enacts. Many of the State codes inflict penalties on ministers or justices for celebrating the marriage of minors without the consent of the parents or guardians. The original law as to prohibited degrees has been considerably modified in the States. The prohibition of marriage with a deceased wife's sister is said by Bishop to be all but unknown in the United States, Virginia apparently being the only one where it is still retained. Some writers apply the term legislative marriages to cases in which the State by enactment confirms a marriage which was void for some defect. Questions sometimes arise as to whether such enactments are within the constitution of the State.

*France.*—Articles 144–226 of the Code Napoléon prescribe the qualifications and conditions of marriage. The man must be eighteen and the woman fifteen years of age. A son under twenty-five, and a daughter under twenty-one, cannot marry without consent of the father and mother, or of the father only if they disagree, or of the survivor if one be dead. If both are dead grandfather and grandmother take their place. A man after twenty-five and a woman after twenty-one are still bound formally to ask the consent of their parents; until the age of thirty and twenty-five respectively this request must be repeated twice, and after the third application parties are at liberty to marry without such consent. Even after the age of thirty, formal notice must be served on the parents or grandparents one month before marriage. If neither parents nor grandparents be alive, parties under twenty-one require the consent of the family council. These rules apply to natural children when affiliated; those not affiliated require the consent of a specially appointed guardian. Marriage is prohibited between all ascendants and descendants in the direct line, and between persons related by marriage in the same line, between brother and sister, between uncle and niece, and brother-in-law and sister-in-law.

Before the solemnization of marriage banns are required to be published on two distinct Sundays, containing the names, occupations, and domiciles of the parties and their parents. The marriage cannot take place until three days after the second publication, and if a year is allowed to elapse fresh banns must be put up. On the day appointed by the parties, and in the parish to which one of them belongs, the marriage is celebrated by the civil officer or registrar reading over to them the various necessary documents, with the chapter of the code relating to husband and wife, receiving from each a declaration that they take each other for husband and wife, and drawing up the act of marriage. All this has to be done in the presence of four witnesses.

Marriages contracted abroad between French subjects or between French subjects and foreigners are valid in France if celebrated according to the forms of the foreign law, provided the French conditions as to banns and consent of parents have been observed.

*International Law.*—In the "conflict of laws" on the subject of marriage, it has been well settled that the *lex loci* governs. If the marriage is valid by the law of the country where it is celebrated it is recognized as valid everywhere; if invalid there it is invalid everywhere. "This rule," says Story, "has received the most deliberate sanction of the English and American courts and of foreign jurists." The most prominent, if not the only known exceptions, Story considers to be marriages (1) involving incest or polygamy, or (2) forbidden by the public law of a country from motives of policy, and (3) marriages celebrated in a foreign country under circumstances which impose on the parties the law of their own country. Westlake (*Private International Law*, chap. iv.) lays it down as indispensable to the validity of a marriage that the *lex loci* should be satisfied in respect of forms, consent of parents and guardians, and capacity of the parties. The law of the parties' domicile should also be satisfied as to capacity unless when it imposes incapacity of a penal nature unknown to the *lex loci*. Story, in reference to the first of the three exceptions alluded to above, attempted to set up a clear and just moral difference between marriages that are incestuous by the law of nature and those that are so by the municipal law of particular States only, with more particular reference to consanguinity and affinity. "It would be a strong point to put that a marriage perfectly valid between a man and the sister of his former deceased wife in New England would be held invalid in Virginia or England, even though the parties formerly belonged to or were born in the latter country or State. But, as to persons not so belonging, it would be of the most dangerous consequence to suppose that the courts of either of them would assume the liberty to hold such marriages a nullity merely because their own jurisprudence would not in a local celebration of marriage therein uphold it." This position has been expressly disavowed by the English courts. In Brook *v.* Brook it was held that an Englishman's marriage with his deceased wife's sister during a residence in Denmark where the union is lawful is invalid in England. In Hyde *v.* Hyde in the English divorce court it was held that a marriage contracted in a country where polygamy is lawful between a man and a woman who profess a faith which allows polygamy is not a marriage as understood in Christendom; and, although it was a valid marriage by the *lex loci*, and at the time when it was contracted both the man and the woman were single and competent to contract marriage, the court will not recognize it as a valid marriage in a matrimonial suit. The difference in the law of divorce in different countries produces many complications of this kind. It appears that a divorce of an English marriage abroad for cause not recognized in England as ground for a divorce will be upheld in England if the parties were domiciled at the time of the divorce in the foreign state; otherwise not. Compare also the French rule as to marriages of French subjects in foreign countries. The too frequent consequence of these variances is that the same persons are held married in one country and unmarried in another, while their children are legitimate in one country and illegitimate in another. There is no subject in relation to which the establishment of a common code for all civilized nations is more urgently required.

Besides true marriage, with which we have been exclusively dealing hitherto, inferior forms of union have from time to time been recognized, and may be briefly noticed here. These have all but disappeared from modern society, depending as they do on matrimonial restrictions now obsolete.

The institution of slavery is a fruitful source of this kind of debased matrimony. In Roman law no slave could contract marriage whether with another slave or a free person. The union of male and female slaves (*contubernium* was recognized for various purposes; a free woman entering into a union with a slave incurred under the S.C. Claudianum the forfeiture of her own liberty; but the bondwoman might be the concubine of a freeman. In the United States, where slavery was said to be regulated by the principle of the civil law, the marriage of slaves was so far recognized that on emancipation complete matrimony took effect and the children became legitimate without any new ceremony. Such at least is the purport of the more recent decisions.

In Roman law no legal marriage could be contracted unless there was *connubium* between the parties. Originally there was no connubium between plebs and patricians, and the privilege was conceded after a long struggle by the Lex Canuleia. In later times Latini and Peregrini were excluded from connubium except where the right had been expressly conferred. The great matrimonial law of the early empire (Lex Julia et Papia Poppæa) introduced restrictions depending on the condition of the parties which later legislation extended and perpetuated. Senators under that law were forbidden to marry freedwomen or women of inferior rank, and the husband of a freedwoman becoming a senator was set free from his marriage. In the canon law[1] new restrictions were developed. Persons who

[1] The restrictions are enumerated in the following lines:—

Error, Conditio, Votum, Cognatio, Crimen,
Cultus Disparitas, Vis, Ordo, Ligamen, Honestas.
Ætas, Affinis, si Clandestinus et Impos,
Raptave sit mulier nec parti reddita tutæ.

bound themselves not to marry were deemed incapable of marrying. The order of the clergy were forbidden to marry. And disparity of faith was recognized by the early church as a bar to matrimony, *e.g.*, between Christians and pagans, and between orthodox and heretics (see *Dictionary of Christian Antiquities*, art. "Marriage").

CONCUBINAGE, which such restrictions tended to develop, is noticed under a separate heading (*q.v.*). It might be described as marriage which has no consequences, or only slight and peculiar consequences, in legal *status*. In the left-handed or "morganatic"[1] marriages of the German royal families we have the nearest approach ever made by concubinage to true marriage, the children being legitimate, but neither they nor the wife acquiring any right to the rank or fortune of the husband. Under the Royal Marriage Act in England a union of this kind has no matrimonial effect whatever.

Differences of religion are no longer regarded in Christian countries as hindrances to marriage, except possibly in some branches of the Greek Church. But the marriage of persons of different religions frequently requires the intervention of the law as to the faith of the children, more particularly in Europe as between Catholics and Protestants. In some countries the clergy make it a condition of such marriages that the children shall be educated in the Catholic faith. English law gives the father an indefeasible right to dictate the faith of his children, no matter what engagements he may have entered into (see INFANT). The practice on this point varies in Europe—the question being ignored in French law, Germany following in some parts the same rule as England, in others giving effect to ante-nuptial stipulations. In Ireland mixed marriages (*i.e.*, between Catholic and Protestant) were by 19 Geo. II. c. 13 null and void if celebrated by a Catholic priest. This Act is repealed by 33 & 34 Vict. c. 110, which permits mixed marriages to be validly celebrated by an Episcopalian or Roman Catholic clergyman, subject to conditions set forth in section 38. (E. R.)

MARRYAT, FREDERICK (1792–1848), has never been surpassed as a writer of tales of nautical adventure. His own life supplied him with abundant raw materials for his art. The son of a wealthy London gentleman (who sat in parliament for several years for the boroughs of Horsham and Sandwich, and was a writer of verses and political pamphlets), he distinguished himself as a boy by frequently running away towards sea; and at last, at the age of fourteen, he was allowed to enter the navy. His first service was under Lord Cochrane in the famous "Impérieuse," and no midshipman ever had a livelier apprenticeship to the sea. "The cruises of the 'Impérieuse' were," he says, "periods of continual excitement, from the hour in which she hove up her anchor till she dropped it again in port; the day that passed without a shot being fired in anger was with us a blank day." During his two and a half years of service under the daring and active Cochrane, the young midshipman witnessed more than fifty engagements, many of them extremely brilliant, and had experience of every description of service, fighting duels with fairly matched ships of war, engaging gunboats, engaging batteries, storming forts, capturing and cutting out merchantmen. Before the general peace of 1815 he had added considerably to this experience of active service, and gained a wide knowledge of conditions of life on board ship under various commanders. He frequently received honourable mention for his behaviour in action, and in 1818 he received the medal of the Humane Society for "at least a dozen" gallant rescues. He commanded with distinction in the Burmese war of 1824–25. And Marryat's honours were not confined to gallant exploits; he was the inventor of a code of signals, obtained some celebrity as a caricaturist, and was elected an F.R.S.

Marryat brought ripe experience and unimpaired vivacity to his work when he commenced novelist. His first production was *Frank Mildmay, or the Naval Officer*, published in 1829, and his second, published nine months later, *The King's Own*. "I think," Washington Irving wrote to him soon after, "the chivalry of the ocean quite a new region of fiction and romance, and to my taste one of the most captivating that could be explored." This was the general feeling. The freshness of the new field opened up to the imagination, so full of vivid lights and shadows, light-hearted fun, grinding hardship, stirring adventure, heroic action, warm friendships, bitter hatreds, was felt all the more keenly from its contrast with the world of the historical romancer and the fashionable novelist, to which the mind of the general reader was at that date given over. The novels of the sea captain at once won public favour. His first attempt was somewhat severely criticized from an artistic point of view. It was without form, though the reverse of void; he had packed into it matter enough for half a dozen novels. Marryat was accused also of gratifying private grudges by introducing real personages too thinly disguised. He admitted the justice of these criticisms, and rapidly learnt the mechanical part of his new business without losing any of the vivacious charm of his style. *The King's Own* was a vast improvement, in point of construction, upon *Frank Mildmay*; and he went on, through a quick succession of tales, *Newton Forster*, *Peter Simple*, *Jacob Faithful*, *The Pacha of Many Tales*, *Japhet in Search of a Father*, *Mr Midshipman Easy*, *The Pirate and the Three Cutters*, till he reached his high-water mark of constructive skill in *Snarley-yow, or the Dog Fiend* (1837). If he never surpassed this in story-telling art, humorous portraiture, and richness of incident, the records of circulating libraries and the pencilled comments of their subscribers show that his subsequent works—he produced twenty-four in all during his twenty years of authorship—were no less capable of riveting the attention, especially of youthful readers. The following is the list, with the dates of publication:—*The Phantom Ship* (1839), *A Diary in America* (1839), *Olla Podrida* (1840), *Poor Jack* (1840), *Masterman Ready* (1841), *Joseph Rushbrook* (1841), *Percival Keene* (1842), *Monsieur Violet* (1842), *The Settlers in Canada* (1843), *The Privateer's Man* (1844), *The Mission, or Scenes in Africa* (1845), *The Children of the New Forest* (1847), *The Little Savage* (1847), and *Valerie*, not completed by Marryat (1849). Captain Marryat retired from the naval service in 1830, and thereafter worked as hard at literature as any professional man of letters, making special historical and geographical studies for several of the works in the above list. He edited the *Metropolitan Magazine* for four years (1832–36). Marryat's novels were in the first flush of their success when Dickens was a youth, and they have an interest in the history of literature as forming an important link between Smollett and Fielding and the author of *Sketches by Boz*. He died in 1848. There is a biography by his daughter, Florence Marryat.

MARS was a Roman deity whose name has passed into later literature as that of the war god. There grew in Rome a tendency, fostered by Greek influence, to consider Jupiter as the one great god, and the other deities as representing special sides of his character. Mars then was identified with the Greek ARES (*q.v.*), and was regarded as almost the same in nature with the warlike element in Jupiter as Feretrius and Triumphator. In the actual worship of the Romans Mars bears a very different character, which, however, had almost disappeared from the mind of the people before Augustus built in the Forum his temple to Mars Ultor, the avenger of the murder of Julius Cæsar.

Father Mars, Marspiter, Maspiter, Mavors, or Maurs, was the great god of one of the races that composed the Roman state. He is the god of heaven, the giver of light, the opener of the new year; he hurls the thunder and sends

[1] Said to be so called because the wife's rights were limited to the *Morgengabe* (donum matutinale). The common law in Germany permits them to the royal houses and the higher nobility, and the law of Prussia to the lower nobility also. Inequality of condition (Unebenbürtigkeit) is not necessary to a marriage of this kind, which may be made between persons of equal rank, *e.g.*, with the object of not prejudicing the children of a first marriage by allowing full rights to the offspring of a second. A woman of high rank may make a morganatic alliance with a man of inferior position.

the rain. In cases of drought the *lapis manalis*, which was kept in his temple on the Appian Way, was carried through the city by the *pontifices*. The first month of the old Roman year was the month of Mars, still called March. On the first day the god had been born; and on the same day various annual ceremonies both political and religious took place; and the holy fire was renewed in the temple of Vesta. When Mamurius Veturius, *i.e.*, Mars of the Year (*vetus*, Greek *Féros*), was beaten out of the city on March 14, the intention was originally to symbolize the driving away of the old year. The spear sacred to Mars was in its original sense doubtless the lightning, and his sacred shield was, like the ægis of Zeus and Athene, the storm shield, *i.e.*, the thundercloud. The Sabine words Marmar and Mamers (akin to μαρμαίρω) are evidently names of the heaven-god. The wolf which was sacred to Mars may be compared with the wolves of Zeus Lycaios, and the horse, the sacrifice of Mars, is the horse of the sun, which the Greeks also sacrificed to Helios.

As heaven-god and sender of rain, Mars is the giver of fertility and increase. Hence in some of the oldest cults he is the god of the land, of agriculture, and of the flocks. As he was powerful to send fertility, so he could cause also drought, sterility, and all evil; and propitiatory ceremonies, such as the Ambarvalia, were consecrated to him. The Arval brothers invoked Mars to assist them and to avert pestilence. In the Robigalia a sheep and a reddish dog were sacrificed by the flamen of Mars to avert mildew from the crops. The sacrifice of the "October horse" in the Campus Martius, whose head the people of the Subura and the Sacra Via struggled for in order to hang it up in their own precincts, had also a naturalistic and apotropaic character. In times of calamity there was an old Italian custom of dedicating to Mars a *ver sacrum*. Everything born in this spring was the property of the god; the animals were sacrificed, the young men when they grew up were sent out of the country. Mars seems also to have had some relation to the religious ceremony of marriage. Along with Juno, the goddess of women and of childbirth, he was worshipped by the Roman matrons on June 1 and at the Matronalia on March 1. As god of the land and giver of increase, Mars was also the god of death and the dead; he was one of the deities invoked by Decius when devoting himself to death. He was likewise the giver of oracles: like Zeus he revealed his will to men by certain signs. His ancient oracle at Tiora Matiene near Cære resembled in character the oracle of Zeus at Dodona, in so far as revelation took place by the medium of sacred birds and trees. Woodpeckers were the sacred birds of Mars, and the noise which they made tapping on the trees was one of the simplest methods of revelation. Picus, the woodpecker, was a name or form of Mars, and was ultimately individualized as a local hero, an early king of Latium, and son of the god. Faunus, the favouring deity, son of Picus, is pre-eminently the god of prophecy; he also is closely related to the original Italian character of Mars, which he retained far more truly than the great Roman god.

Although the worship of Mars was known both in Latium and in Etruria, it was probably of Sabine origin. Quirinus, an undoubtedly Sabine word, is merely a name of Mars, which never acquired complete individuality; the feeling always remained alive in Rome that Mars and Quirinus were one, although they had separate priests. It is in accordance with the Sabine character that the warlike element should have been very strong in their conception of deity; and thus the Sabine Mars became in the Roman pantheon the deity of war. Besides the ceremonies round the altar of Mars in the Campus Martius, the oldest cults of the god in Rome are the Sabine worship of Quirinus on the Quirinal and the Latin worship of the holy spear of Mars in the temple of Vesta. There likewise grew at an early time a cultus of the god on the Palatine, said to have been founded by Numa, and twelve Salii of the Palatine existed alongside of the twelve Quirinal Salii. The Palatine Salii performed one of the most remarkable ceremonies in the Roman worship of Mars. For many days, beginning from March 1, they danced in armour through certain parts of the city, clashing their lances on their shields, and repeated the prescribed song. The shields which they carried were the twelve sacred *ancilia* preserved on the Palatine. One of these, it was said, fell from heaven in the time of Numa, and the king, in order to preserve safely this pledge of victory for the state, had eleven others exactly like it made by Mamurius Veturius. The song of the Salii, besides mentioning all the gods of the city, referred to Mamurius, whose name is only a form of Mamers.

Next to Jupiter, Mars was the chief protecting god of the Roman state. Quirinus Mars was the father of the twin-founders of the city, and his sacred wolf was the emblem of the city and the foster-mother of the twins. The Campus Martius outside the city was dedicated to the god from a very early time; there the young men practised their warlike exercises; there the horse races, *equiria*, in honour of Mars (February 27) and the sacrifice of the "October horse" took place. There also was held the census every fifth year, followed by the purificatory ceremonial for the whole city, which was dedicated to Mars. When war broke out, the Roman general clashed the shield and spear in the temple of Mars and invoked the god; the spoils of victory belonged to him after Jupiter Feretrius.

There was an ancient temple of Mars outside the Porta Capena on the Appian Way; and on the ides of July, in commemoration of the battle of Lake Regillus, the knights had a procession

> "From Castor in the Forum,
> To Mars without the wall."

As the god of war, who marched with his people to battle, Mars was Gradivus; such at least was the later explanation of an old religious name. Inuus Lupercus, the averter, to whom the Lupercalia was dedicated, was probably a local form of Mars; his character as protector of the Palatine city, and the warlike element in him, resemble Mars (see LUPERCALIA). Silvanus is also closely related to the agricultural god Mars, who is sometimes called Mars Silvanus. A goddess named Nerio or Neriene is sometimes mentioned as wife of Mars. There was also a goddess Bellona, whose name marks her strictly as the goddess of war; she is called the sister or daughter or wife of Mars. Quirinus, on the Quirinal, had a festival called Quirinalia, on the 17th of February.

See Preller, *Röm. Mythol.*, and the other books on Roman religion; Marquardt on religious antiquities; Unger, "Lupercalia," *Rhein. Mus.*, 1881; Jordan, *Stadt Rom*; Roscher, *Apollo und Mars*; and on the Etruscan Mars, Müller, *Etrusker*, ed. Deecke, ii. 57 and 169.

MARSALA, a seaport on the west coast of Sicily, in the province of Trapani, 20 miles south of Trapani, to the north of the river Marsala, with a station on the railway between Trapani and Palermo. A flourishing and well-built town, with wide paved streets, it possesses a castle, a cathedral, a theatre, cavalry barracks (now occupied by Government offices), an academy of science and literature, and a public library. The Corinthian columns of the cathedral were originally intended for the cathedral at Canterbury, and owe their present destination to the wreck of the vessel which was conveying them to England. After the destruction of its harbour in the latter part of the 16th century as a precaution against its occupation by

the Turkish pirates, the commercial importance of Marsala remained in abeyance till the construction of the new port to the south of the town. The sea-wall for this was begun in 1818; but it was not till 1835–36 that the pier was constructed. A great part of the surface of 44 acres constituting the port is now silted up; new works, however, on an extensive scale, are being undertaken. The wine trade, which forms the staple, was commenced in the end of the last century by Woodhouse & Co.; and the wines first got into favour by being supplied to the English fleet in 1802. They are for the most part white, and are usually "fortified." The number of seagoing vessels that entered at Marsala in 1863 was 149, with a burden of 9791 tons; in 1880 there were 249 vessels of 16,645 tons. From 31,350 in 1861 the population of the commune had increased by 1881 to 40,251; that of the town was 14,105 in 1871, or, with the suburbs of Porta Garibaldi, Porta Mazzara, and Porta Trapani, 17,666.

On the small island of San Pantaleone, about 6 miles north of Marsala, lay the Carthaginian stronghold of Motya (Ital., *Mozia*).[1] After the destruction of this settlement by Dionysius in 397 B.C. the defeated party established a new colony on the neighbouring promontory of Lilybæum. It was there that in 276 B.C. the Carthaginians held out successfully against Pyrrhus, who had already driven them from the rest of Sicily; and it was only after a siege of ten years that in the first Punic War they were obliged to surrender the fortress to the Romans. Under its new possessors Lilybæum continued to flourish and became the residence of one of the two quæstors of Sicily. It was still an important city under the later empire, and when occupied first by the Goths and then by the Vandals. The Arabs called it Mersá 'Aly, "port of 'Aly," and Edrisi (12th century) describes it as a considerable town, which, having been ruined, had been restored by Roger I. It was at Marsala that Garibaldi began his Sicilian campaign in 1860.

MARSDEN, William (1754–1836), an eminent Oriental scholar, was the son of a Dublin merchant, and was born in 1754. After studying at Trinity College, he obtained an appointment in the civil service of the East India Company, and set sail for Bencoolen, Sumatra, in 1771. There he soon rose to the office of principal secretary to the Government, and was at the same time intent on acquiring that intimacy with the Malay language, and that knowledge of the country, which were afterwards the sources of his literary reputation. Returning to England in 1779 with a pension, he retired into literary seclusion, and in 1782 produced *The History of Sumatra*. Marsden was appointed in 1795 second secretary and afterwards first secretary to the admiralty. In 1807 he retired again into private life, and, devoting himself to study, published in 1812 his *Grammar and Dictionary of the Malay Language*, and in 1817 his translation of the *Travels of Marco Polo*. A pension of £1500, which he had received on his retirement from office, he voluntarily resigned in 1831 for the behoof of the public. In 1834 he presented his rich collection of Oriental coins to the British Museum, and his library of books and Oriental MSS. to King's College, London. He died of apoplexy in October 1836.

Marsden's other works are—*Numismata Orientalia*, London, 1823–25; *Catalogue of Dictionaries, Vocabularies, Grammars, and Alphabets*, 1796; and several papers on Eastern topics in the *Philosophical Transactions* and the *Archæologia*. His name will also be remembered in connexion with African philology, as he had—the first in England, and, it would appear, independently of Lichtenstein and Vater—drawn attention to the affinity of the Congo and Mozambique languages with those spoken by the Kaffre race. See Tuckey's *Narrative of an Expedition to explore the River Zaire*, London, 1818, p. 386 *sq.*

MARSEILLES (Fr. *Marseule*), the third largest city of France, and the chief commercial port of the Mediterranean, in 43° 17′ N. lat. and 5° 22′ E. long., is the chief town of the department of Bouches du Rhône, headquarters of the 15th army corps, the seat of a bishop, and of numerous commercial and scientific institutions. The population (1881) is 360,099.

The old harbour of Marseilles opens on the west to the Gulf of Lyons; and the famous Rue de la Cannebière, leading east-north-east from the inner end of the harbour, and continued by the Rue de Noailles, the Allées de Meilhan, and the Boulevard de Longchamps, to the Palais des Arts, forms the first main artery of the town. A second great artery, at right angles to the first, connects the Aix gate and its triumphal arch with the grand Promenade du Prado, by the Cours Belsunce and the Rue de Rome. North of the old harbour, between the Aix gate and the sea, lies the old town of Marseilles. The finest streets, the Rue St Ferréol, the Rue Paradis, and the Rue de Breteuil, are to the south of the Rue Cannebière,

Plan of Marseilles.

running parallel with the Rue de Rome, between it and the foot of the hill upon which is Notre Dame de la Garde. From La Cannebière to La Joliette, the centre of the new docks, runs the broad Rue de la République, lined with fine buildings, and opening a line through the oldest part of the town. The entrance to the old harbour is defended by Fort St Jean on the north and Fort St Nicolas on the south. Behind the latter is the Anse (Creek) de la Réserve. Beyond this again, situated in succession along the shore, come the old imperial palace, the Anse du Pharo, the military exercising ground, and the Anse des Catalans. The new parts of the town extend in this direction to the Vallon d'Endoume behind Fort St Nicolas. To the old harbour, which covered only 70 acres, the basin of La

[1] The ruins of Motya were excavated by Schliemann in 1876. See *Academy*, March 1876, p. 288.

Joliette (55 acres) was added in 1853. Communicating with the old harbour by a channel which passes behind Fort St Jean, this dock opens on the south into the outer harbour, opposite the palace and the Anse du Pharo; it is separated from the roadstead on the west by a simple jetty. A series of similar basins have since been added along the shore to the north, viz., the Lazaret or "Bassin des Docks" (37 acres), that of Arenc (59 acres), the "Bassin National," twice as large as the preceding, and the graving dock of 20 acres; a fine revolving bridge, worked by steam, separates the graving dock from the rest. Farther out, the Château d'If and the islets of Pomègue and Ratonneau, where vessels formerly did quarantine, have 45 acres of harbour accommodation. The port of Marseilles has in all an area of 422 acres, but there are only 4½ miles of quays, an amount of accommodation quite inadequate for the enormous traffic, now amounting to more than 3,400,000 tons. Protected on the east by Cape Croisette, and on the west by Cape Couronne, the roadstead of Marseilles and its approaches are lighted by six lighthouses, of which the most distant (130 feet high) is 8 miles south-west of the town, on the Planier rock. The docks along the Lazaret basin cover an area of 45 acres, and the company to which they belong also holds a large area of ground for their enlargement, and has exclusive rights over 1½ to 2 miles of quays. The warehouses occupy 27 acres of floor space on their several stories, and the 200,000 tons of goods for which they afford storage are easily manipulated by powerful hydraulic machinery wrought by steam. From the harbour station at the docks the railway is carried up to the principal station, "Gare St Charles," which commands the town. The Toulon line goes round the zoological gardens, and the whole upper part of Marseilles, and sends a branch to the Prado station. There is a fourth station to the south of the old harbour near the custom-house, and at the foot of the steps of St Victor; it is proposed to join it by a tunnel to the Marseille-Prado station. The large steam vessels for trading with Algiers, the Levant, and the further East lie in La Joliette, but the old harbour still displays the ancient characteristics of Marseilles. The old-fashioned Mediterraneau traders with their lateen sails are crowded together in the Rive Neuve Canal to the south, while the sailing vessels of heavy tonnage are moored to the quay by their sterns. At the end of the old harbour opens out La Cannebière, so called from former rope-walks, of which it occupies the site; it is now the liveliest part of the town, where the principal cafés, shops, hotels, naval and commercial agencies, as well as the Bourse, are found.

Despite its antiquity, Marseilles has no ancient monuments. The old cathedral, which superseded a temple of Diana, itself preceded, it is said, by an altar of Baal, has given place to a modern structure, of which the exterior only is completely finished. It is a Byzantine basilica, in the form of a Latin cross, 460 feet long, built in grey Florentine stone blended with white stone from the neighbourhood of Arles. Near the cathedral stands the bishop's palace. The cathedral is situated at the entrance of the harbours, but a more distant church has superior attractions for the sailors,—the celebrated Notre Dame de la Garde, the steeple of which, surmounted by a gilded statue of the Virgin, 30 feet in height, rises 150 feet above the summit of the hill on which it stands, commanding a view of the whole port and town, as well as of the surrounding mountains and the neighbouring sea. The present chapel of Notre Dame de la Garde occupies the site of one built in 1214. Like the new cathedral it is in the Byzantine style, and constructed of the richest materials.

Descending from Notre Dame by steps, with shops on both sides containing objects of devotion, such as medals and chaplets, and passing the Promenade Pierre Puget, which affords another fine view of the sea, we reach the church of St Victor, close by Fort St Nicolas. Originally an abbey founded about 410 by St Cassian, it was afterwards destroyed by the Saracens, but rebuilt in the 11th century; destroyed a second time, it was finally restored by Pope Urban V., a former abbot, who surrounded it in 1350 with high square crenellated towers. Tradition relates that St Lazarus inhabited the catacombs under St Victor; and the black Virgin, still preserved there, is popularly attributed to St Luke. The spire of the ancient church des Accoules marks the centre of Old Marseilles. At its foot are a "Calvary" and a curious chapel of modern construction in rock work. Notre Dame du Mont Carmel, also in the old town, occupies the place of what was the citadel of the Massaliots when they were besieged by Julius Cæsar. The new Hôtel de la Préfecture, at the end of the Rue St Ferréol, the Palais de Justice, and the Bourse, are all buildings of the last twenty years. The first is a palatial edifice 300 feet long and 260 wide, adorned with statues and bas reliefs; it has a fine staircase and large reception rooms, decorated with paintings. Before the Palais de Justice stands a statue of Berryer. The pediment and peristyle are decorated with bas reliefs by Guillaume. The outer hall is surrounded by beautiful pillars of red marble. The Bourse has in the vestibule a bas relief representing Marseilles receiving the productions of all parts of the world, and allegorical statues of Marseilles and France. The hall is larger than even that of the Bourse at Paris. The hall of the Chamber of Commerce, at whose cost the whole edifice was built, is remarkable for the magnificence of its mural paintings and gildings. The Hôtel de Ville, an old and unimportant building, stands on the quay to the north of the old harbour. The Palais des Arts de Longchamps, completed in 1870, is a work of consummate taste; it is built at the terminus of the Canal de Marseille, that great work which has metamorphosed the town and its surroundings by bringing into it the waters of the Durance. This canal, which leaves the river opposite Pertuis, has a length of 94 miles, of which more than 15 are underground. It crosses the valley of the Arc, between Aix and Rognac, by the magnificent aqueduct of Roquefavour, comparable with the noblest works of ancient or modern times. The canal then purifies its waters, charged with ooze, in the basins of Réaltort, sets in motion seventy-two mills, which it supplies with upwards of 1200 horse-power, carrying about 200 cubic feet of water per second to the district of Marseilles. Right and left of the Château d'Eau, which occupies the centre of the Palais de Longchamps, and is 128 feet in height, are the picture gallery, a fine collection of ancient and modern works, and the natural history museum, remarkable for its conchological department and the interesting collection of ammonites. Behind are extensive zoological gardens, with the astronomical observatory, one of the most important in France. The museum of antiquities is established in the Palais Borély, in a fine park, recently purchased by the town, at the end of the Prado, and approached by the two finest promenades of the city. It includes a Phœnician collection (containing the remains that support the hypothesis of the Phœnician origin of Marseilles), an Egyptian collection, numerous Greek, Latin, and Christian inscriptions in stone, &c. A building within the city, recently finished, 177 feet by 64, with an imposing façade, contains the school of art and a valuable library. The triumphal arch of Aix, originally dedicated to the victors of the Trocadero, was in 1830 appropriated to the conquests of the empire.

Marseilles contains large hospitals. The Hôtel Dieu in the old town was founded in 1188, and rebuilt in 1593; it has 450 beds. The Hospice de la Charité, in the same neighbourhood, accommo-

dates 600 patients, while at the opposite extremity of the town, near the Prado station, are the modern Hôpital de la Conception (with 800 beds), the military hospital, and the lunatic asylum.

The scientific institutions of the town are also numerous, including a faculty of science, an astronomical observatory, a preparatory school of medicine and pharmacy, a musical conservatoire, a school of art, a lyceum, and many private institutions. The principal learned societies are the academy of science, letters, and art, the medical association, and the geographical, statistical, agricultural, and horticultural societies.

The mean temperature of Marseilles is 58° Fahr.; frost is rare, and snow almost unknown. The heat of summer is tempered during the day by the cooling sea breeze. The most disagreeable wind is the mistral, a violent and cold north-west wind, which blows on an average one hundred and thirty-eight times a year, but has at least the advantage of restoring salubrity to the frequently unhealthy shores of the Mediterranean. The sirocco, a south-east wind, blows some sixty times a year; though hot and parching in summer, it softens the winter climate. The east-south-east wind is cold and damp, and brings rain. The Canal de la Durance has greatly modified the climate of Marseilles and its neighbourhood, for by restoring vegetation it has increased the fogs and rains; there is now an annual rainfall of nearly 24 inches.

Marseilles is at once the largest commercial port of France and a manufacturing town, working up the raw materials brought in by sea from every part of the world. The leading industry is that of soap-making, which occupies sixty factories with 1200 artisans, and annually produces 65,000 tons, valued at £2,000,000 sterling. With this manufacture are connected oil and chemical works; in the former, which employ 2000 to 2500 workmen, 55,000 tons of different oils are produced yearly. The chemical works comprise a dozen mills, manufacturing chiefly the salts of soda and concentrated acids. Two thousand operatives are there employed, and the value of their annual production is estimated at £320,000. There are also three sugar-refineries, producing 65,000 tons of loaf-sugar, of which more than half is re-exported. Sulphur from Sicily too is refined and converted into sticks or flowers of sulphur, to the value of £80,000. Petroleum refining occupies 100 workmen. Metallurgy is another great industry; a large quantity of ore, imported from Elba, Spain, and Algeria, is smelted in the blast furnaces of St Louis in the suburbs. The Mediterranean iron-works and yards, together with other private companies, have large workshops for the construction or repair of marine steam-engines and every branch of iron shipbuilding, employing several thousand workmen. Marseilles is a great centre for the extraction of silver from lead ore; 16,000 tons of lead and 25 tons of fine silver are separated annually. There are 64 flour-mills with 300 sets of stones, and 100 factories prepare semolina and other cereal pastes, while 34 tanyards dress 500,000 sheep skins and 335,000 goat skins. To this list of industries must be added the manufactories of matches, candles, and wax-lights, with brass foundries, glass-works, and manufactures of coral, and of Oriental hosiery.

The port of Marseilles is the centre of numerous lines of steamers. The French company of mail steam packets (*Messageries Maritimes*) despatch their boats regularly to Italy, Egypt, Réunion, India, China, and the far East, as well as to Greece, Turkey, the Black Sea, Smyrna, and Syria. The Transatlantic Company runs its vessels to Algiers, Tunis, Malta, and the coast of Italy, and has also a regular line between Marseilles and New York. Many private companies have services to Corsica, Algiers, the coast of Languedoc and of Spain, and the Italian Riviera. Other lines connect Marseilles with Brazil and La Plata, Havre, and London. Landward there are two lines of railway to Aix, and a third to Toulon. A navigable canal is greatly needed to connect the port directly with the Rhone, in order to avoid the difficulties of egress from the river and to make Marseilles the natural outlet of the rich Rhone basin. The countries with which the greatest traffic is maintained are Algeria, Spain, Italy, Turkey, and the Russian ports on the Black Sea; next in order come England, Austria, the western coast of Africa, Réunion, the Cape, British India, Brazil, the Antilles, China, and Senegambia. From the Black Sea, Turkey, and Algeria come the cereals which form the chief imports in point of bulk; from Italy, Spain, the Levant, China, and Japan the silk, which is the import of greatest value (£4,000,000 yearly). Then follow ores and metals, iron, cast iron, lead, and copper; also wood, raw material for oil manufacture, raw sugar, cattle, wool and cotton, rice, and various dry vegetable foods, petroleum, cocoa, gums, pepper, and other spices, wines and brandies, coal, skins, cod-fish, cheese, and sponges. The principal exports in respect of value are silk, woollen, and cotton fabrics, refined sugars, wines and spirits; those of greatest bulk are cereals in the form of grain or flour, coal, building materials, oil-cakes, iron and other manufactures in metal, wines and spirits, oils, glass and crystal, lead, and coffee.

Of the seagoing tonnage, one-third is under the French flag, but the coasting trade, carried on by French sailors alone, is almost half as large as the ocean trade. The shipowners of the port possess almost seven hundred vessels, without counting the hundreds of fishing boats which ply along the coast.

*History.*—The Greek colony of Massalia (in Latin, *Massilia*) was founded by the enterprising mariners of Phocæa in Asia Minor, about 600 B.C. The settlement of the Greeks in waters which the Carthaginians jealously reserved for their own commerce was not effected without a naval conflict; it is, indeed, not improbable that the Phœnicians were settled at Marseilles before the Greek period, and that the very name of the town is the Phœnician קֶדֶל, "settlement." Whether the judges (שֹׁפְטִים, "suffetes") of the Phœnician sacrificial tablet of Marseilles were the rulers of a city older than the advent of the Phœnicians, or were a sort of consuls for Punic residents in the Greek period, is disputed. The fall of the Ionic cities before the Persians probably sent new settlers to the Ligurian coast and cut off the remote city of Massalia from close connexion with the mother country. Isolated amidst alien populations, the Massaliots made their way by great prudence in dealing with the inland tribes, by the vigilant administration of their oligarchical government, and by frugality and temperance united to remarkable commercial and naval enterprise. Their colonies spread east and west along the coast from Monaco to Cape St Martin in Spain, carrying with them the worship of Artemis; the inland trade, in which wine was an important element, can be traced by finds of Massalian coins right across Gaul and through the Alps as far as Tyrol. The Massaliot Pytheas (330–320 B.C.) passed the pillars of Hercules and visited the coasts of Gaul, Britain, and Germany. The great rival of Massalian trade was Carthage, and in the Punic wars the city took the side of Rome, and was rewarded by Roman assistance in the subjugation of the native tribes of the Ligurian mountains. In the war of Cæsar and Pompey the aristocratic town took the side of the latter, and made a courageous but vain resistance to Cæsar. In memory of its ancient services the city, "without which," as Cicero says, "Rome had never triumphed over the Transalpine nations," was still left as a *civitas libera*, but her power was broken and most of her dependencies taken from her. From this time Massalia has little place in Roman history; it became for a time an important school of letters and medicine, but its commercial and intellectual importance gradually declined into insignificance. The town appears to have been Christianized before the end of the 3d century, and its reputation partly revived through the names of Gennadius and Cassian, which give it prominence in the history of Semi-Pelagianism and the foundation of Western monachism.

After the ravages of successive streams of invaders, Marseilles was repeopled in the 10th century under the protection of its viscounts. In 1112 the town bought up their rights, and was formed into a republic, governed by a podestat, who was appointed for life, and exercised his office in conjunction with 3 notables, and a municipal council, composed of 80 citizens, 3 clerics, and 6 principal tradesmen. During the rest of the Middle Ages, however, the higher town was governed by the bishop, and had its harbour at the creek of La Joliette. The southern suburb was governed by the abbot of St Victor, and owned the Port des Catalans. Situated between the two, the lower town, the republic, retained the old harbour, and was the most powerful of the three divisions. The period of the crusades brought great prosperity to Marseilles. The activity of its shipbuilding, the magnitude of its fleet, the importance of its commerce and manufactures, all increased at once. The count of Provence, Raymond Bérenger, Charles of Anjou, and afterwards Alphonso of Aragon, successively attempted to make themselves masters of the town; it suffered at different times from incendiarism, pillage, and massacre during the 13th and 14th centuries, and in the beginning of the 15th. King René, who had made it his winter residence, however, caused trade, arts, and manufactures again to flourish. Under Francis I., the disaffected constable de Bourbon vainly besieged the town with the imperial forces in 1524. During the wars of religion, Marseilles took an active part against the Protestants, and long refused to acknowledge Henry IV. The loss of the ancient liberties of the town brought on new disturbances under the Fronde, which Louis XIV. came in person to suppress. He took the town by storm, and had Fort St Nicolas constructed. Marseilles repeatedly suffered from the plague, and an epidemic raged from May 1720 to May 1721 with a severity for which it is almost impossible to find a parallel; Bishop Belsunce, Chevalier Rose, and others immortalized themselves by their courage and devotion.

During the Revolution the people rose against the aristocracy, who up to that time had governed the commune. In the Terror they rebelled against the convention, but were promptly subdued by General Carteaux. The wars of the empire, by dealing a severe blow to their maritime commerce, excited the hatred of the inhabitants against Napoleon, who accordingly hailed with enthusiasm the return of the Bourbons and the defeat of Waterloo. The news of the latter provoked a bloody reaction in the town against those suspected of imperialism. Since 1815 the prosperity of the city

has received a considerable impulse from the conquest of Algeria and the opening of the Suez Canal. The completion of the canal of the Durance has covered with verdure the formerly arid country surrounding the town, and the openings made in the old part of Marseilles have improved its sanitary condition. (G. ME.)

MARSH, GEORGE PERKINS, LL.D. (1801–1882), American diplomatist and philologist, was born at Woodstock, Vermont, March 17, 1801, graduated at Dartmouth College in 1820, and practised law at Burlington, Vermont, devoting himself also with ardour to philological studies. In 1835 he was elected to the State legislature, and in 1842 he became a member of Congress. In 1849 he was appointed United States minister to Turkey, and in 1852 discharged also a special mission to Greece, returning to Vermont in 1853. In 1861 he became United States minister to Italy, and died in that office at Vallombrosa, July 24, 1882.

His chief published works are a *Compendious Grammar of the Old Northern or Icelandic Language*, 1838, compiled and translated from the grammar of Rask; *The Camel, his Organization, Habits, and Uses*, 1856; *Lectures on the English Language*, 1861; *The Origin and History of the English Language*, 1862; *Man and Nature*, 1864. The last-named work, largely rewritten, was issued under the title *The Earth as Modified by Human Action* in 1874.

MARSHAL (from Old High German *marah*, horse, and *scalc*, care-taker), in its original signification a servant of the royal *manége*, was afterwards a title given in different countries to the holder of various high offices, military and civil. In the time of Philip Augustus the commander of the French forces was called the marshal of France. Under Francis I. the marshals of France became two in number, under Henry III. four, and in the time of Louis XIV. their number was raised to twenty. In England the marshal was a high officer of state as far back as the 12th century. In the end of the 12th and first half of the 13th century the office was conferred on the earls of Pembroke, from whom it passed by female descent to the family of Bigod, earl of Norfolk. The dignity of earl-marshal was afterwards held successively by the Mowbrays, dukes of Norfolk, the Howards, dukes of Norfolk, and the earls of Arundel and Norwich. Under a grant by Charles II. to Henry Howard, earl of Norwich, it has descended to and continues in the line of the existing dukes of Norfolk. The marshal was in feudal times (in conjunction with the constable, a still higher officer) the judge in the court of chivalry, which had cognizance of questions of honour and dignity; and, when the king headed his army in person, it was the marshal who selected the proper spot for the encampment of each noble. The constable's powers and duties were superseded in the reign of Henry VIII.; but the earl-marshal is still the head of the Heralds' College, and appoints the officers of arms. In Scotland (an orthography resembling the French maréchal being adopted) the office of marischal, probably introduced under David I., became from the 14th century hereditary in the family of Keith. The Scottish marischal became an earl under the designation of "earl-marischal" in 1458. Marischal College in Aberdeen was founded and endowed by the munificence of George, 5th earl-marischal. The dignity came to an end by the attainder of George, 10th earl-marischal, in 1716. The military title of field-marshal was at first borrowed by the Germans from the French *maréchal de champs*; and in the Thirty Years' War it meant much what quartermaster-general does now. It was not till last century that the word rose in dignity so as to signify the highest military dignity except that of commander-in-chief. It was adopted into the British military system from Germany,—the first field-marshals being John, duke of Argyll, and George, earl of Orkney, made so by George II. in 1736.

MARSHALL, JOHN (1755–1835), chief justice of the United States, was born in Fauquier county, Virginia, on September 24, 1755. As lieutenant and captain he served in the revolutionary army from 1775 to 1780. In 1781 he began the practice of the law, and two years later removed to Richmond. At various times from 1782 to 1798 he was elected a member of the Virginia legislature, in 1788 a member of the Virginia convention for the ratification of the constitution; in 1797 he was envoy-extraordinary to France, and in 1799 a member of Congress; in 1800 he became secretary of state; and on January 31, 1801, he was appointed to the chief justiceship, which position he held until his death on the 6th of July 1835. Marshall as a lawyer soon rose to the first rank at the Virginia bar, and acquired also a national reputation. In the Virginia convention of 1788 his influence was second only to that of Madison in securing the adoption of the constitution. But, unlike Madison, he continued, under the constitution, to support the administration of Washington and Federalist measures in general. It was as chief justice of the supreme court of the United States, however, that Marshall won lasting fame. His reports, filling about thirty volumes, form a work which time will only render more valued. In the expounding of public law, whether international or State law, his talents found their freest scope. In these departments of jurisprudence general principles rather than authority must be sought by the judge, and in their application Marshall has had no equal upon the American bench. It is the peculiar function of the supreme court of the United States to interpret the constitution and to guard it from the encroachments of both national and State legislation. To this duty Marshall brought his great and just powers of reasoning, as well as those broad views of government which, during the thirty-four years of his judicial career, gave to the constitution the liberal powers which were necessary to its durability. "The constitution," says Judge Story, "since its adoption, owes more to him than to any other single mind for its true interpretation and vindication." See biography by Henry Flanders in his *Lives of the Chief Justices*, vol. ii.

MARSHALL ISLANDS. See MICRONESIA.

MARSHALLTOWN, the county seat of Marshall County, Iowa, United States, is situated on the Iowa river at the junction of several railways, and in the midst of a grain and stock producing region. Among its numerous industries are sugar-refining, waggon-making, and the manufacture of barbed steel wire for fencing purposes. The population was 3218 in 1870 and 6240 in 1880, and has since increased rapidly.

MARSHMAN, JOSHUA (1768–1837), a Baptist missionary and Oriental scholar, was born on April 20, 1768, at Westbury Leigh, in Wiltshire, where he received a somewhat defective school education, and afterwards followed the occupation of a weaver until 1794, when he removed to Bristol to take charge of a small school there. Meanwhile he had been diligent in the cultivation of his talents, which were naturally good; and he was already a man of considerable acquirements when in 1799 he was sent by the Baptist Missionary Society to join their establishment at Serampore. Here, in addition to the discharge of his more special duties, he engaged with success in the study of Bengali and Sanskrit, and afterwards of Chinese, and accomplished numerous literary tasks, the more important of which are mentioned below. He received the degree of D.D. from Brown University, U.S.A., in 1811. His death took place at Serampore on December 5, 1837.

Dr Marshman translated into Chinese the book of Genesis, the Gospels, and the Epistles of Paul to the Romans and the Corinthians; in 1811 he published *The Works of Confucius, containing the Original Text, with a Translation*, and in 1814 his *Clavis Sinica*. He was also the author of *Elements of Chinese Grammar, with Preliminary Dissertation on the Characters and Colloquial Mediums of the Chinese*, and was associated with Carey in the preparation of a

Sanskrit grammar and of a Bengali-English dictionary. See J. C. Marshman's *Life and Times of Carey, Marshman, and Ward* (2 vols., 1859).

MARSIGLI (Latinized MARSILIUS), LUIGI FERDINAND, soldier and savant, was born at Bologna, July 10, 1658, and died in the same city, November 1, 1730. After a considerable course of study in mathematics, natural history, and anatomy, he visited Constantinople, and on his return to Christendom offered his services to the emperor Leopold, then at war with the Turks (1682). Wounded and captured in an action on the river Raab, he was sold to a pasha and accompanied him to the siege of Vienna; but in 1684 his friends purchased his release, and at the close of the war he was appointed commissioner for fixing the new Dalmatian boundary. In 1703 he was second in command to the count of Arco when Alt-Breisach was surrendered to the duke of Burgundy; and, though popular opinion acquitted him of blame, Marsigli was cashiered when Arco was condemned to death. Devoting himself to scientific pursuits, he visited Switzerland, and spent a considerable time at Paris and Marseilles. He went to Rome in 1709 at the request of Clement XI., but soon returned to Marseilles to prosecute his investigations into the physical nature of the sea. In 1712 he presented his scientific collections to his native city, and thus gave rise to the Bologna Institute of Science and Art; and about the same time he established a press, including founts of Oriental characters, for printing the publications of the society.

Marsigli's own works were valuable contributions to knowledge, brought out in very handsome style. Best known are his curious physical history of the sea (Italian, Venice, 1711; French, Amsterdam, 1725), with a very laudatory preface by Boerhaave; *L'état militaire de l'Empire Ottoman* (Amsterdam, 1732); and *Danubius Pannonico-Mysicus* (Hague, 1726). This last, of which only three hundred and seventy-five copies were printed, consists of six huge folio volumes illustrated by nearly three hundred maps and engravings, and furnishes an exceedingly elaborate account of the course of the Danube, of the towns and antiquities along its banks, of its birds, beasts, fishes, &c. See Fontenelle's *éloge* in *Mém. de l'Acad. des Sciences*, Paris, 1730; Quincy, *Vie de Mons. le Comte de Marsigli*, Zurich, 1741.

MARSTON, JOHN, was one of the most vigorous satirists and dramatists of the Shakespearean age. He was probably some ten years younger than Shakespeare He has been identified with a gentleman commoner of Brasenose College, Oxford, who entered in 1591, and was admitted B.A. in 1593 as the eldest son of an esquire. If this is the same John Marston that was buried in the Temple Church in 1634, under a tombstone *Oblivioni sacrum*, the identification of him with the poet is most probably right, for one of Marston's most singular poems is a prayer to Oblivion—

> "Let others pray
> For ever their fair poems flourish may;
> But as for me, hungry Oblivion,
> Devour me quick."

In the superfluity of learned allusions and Latin quotations in his plays Marston proclaims the fact that he was a university man. He entered the field of letters in 1598, as a satirist, with a *Scourge of Villany*. He was professedly an imitator of Juvenal, but he wrote rather in the spirit of Skelton, and speedily earned something like Skelton's reputation as a coarse ribald buffoon of astonishing energy, girding at the grossest vices of the time in "plain naked words stript from their shirts." There was more of the good-natured chuckling buffoon than of the cynic in Marston's satire, though he did profess unmeasured scorn for the vices and fopperies of his age. The coarse energy of his invective pours out as if he loved strong language more than he hated the subjects of his ridicule. Shakespeare's *Venus and Adonis* was one of Marston's first butts; in his *Pygmalion's Image* (1598) the wooing of Adonis by the queen of love is very roughly but very cleverly parodied. The freshness and vigour of Marston's vein brought him at once into notice. He is mentioned (misspelt as Maxton or Mastone) in Henslowe's *Diary*, in 1599, as "the new poet" receiving payment as part author of a play; and in the same year he was probably ridiculed by Ben Jonson as "Carlo Buffone" in *Every Man out of his Humour*. He and Dekker had a famous quarrel with Jonson arising out of the latter's attack upon them in the *Poetaster* (see DEKKER). The literary enemies were reconciled; Marston forswore literary quarrels, dedicated a play to Jonson in terms of high eulogy, and was conjoined with Jonson and Chapman in the play of *Eastward Ho!* some political allusions in which nearly cost the authors their ears. Marston wrote comparatively few plays, published in quick succession at the following dates:—*Antonio and Mellida* (1602); *Antonio's Revenge* (1602); *The Malcontent* (1604, his first and most powerful play); *The Dutch Courtesan* (1605); *Parasitaster* (1606); *Sophonisba* (1606); *What You Will* (1607). Marston then apparently left off play writing; if he lived till 1634, there is no explanation of his sudden stoppage. There is very little constructive skill in his plays; the plots are uninteresting. He does little more than send a procession of puppets across the stage, one or more of which "gird at" the others—very "loose libertines" and very contemptible some of them—in the author's own rough vein of satire. One scene in *Antonio and Mellida* was much admired by Charles Lamb, and either suggested or was suggested by one of the most powerful situations in *King Lear*. But the passage taken out of the body of the play gives a very misleading idea of its general tenor, or of the general cast of Marston's dramatic work.

MARSYAS was a Phrygian god, whose name has passed into Greek mythology. It is hardly possible to discover the real basis of the legends, as their original form has been so much altered. Marsyas was the god of a small river which rose in a cave in the agora of Celænæ, and flows into the Mæander. In this cave was hung a hide, which according to the story was the skin of Marsyas suspended there by Apollo. When Athene threw away her flute, Marsyas found it, a subject represented by the sculptor Myron. Proud of his skill, Marsyas challenged Apollo with his lyre. Midas the Phrygian king, appointed judge in the contest, preferred the flute-player, and got his ass's ears in reward for his stupidity. The contest and the punishment of Marsyas, who was flayed alive by Apollo, were frequent subjects for Greek art, both vase-painting and sculpture. There can be little doubt that this account has been very much altered from its native Phrygian form by the Attic comic poets, with whom Marsyas was a favourite character. With regard to the Phrygian god it is difficult to say more than that he and Silenus and Midas are associated in legend with Dionysus, and that he must therefore belong to the cycle of legends of Cybele (see Preller, *Gr. Mythol.*, i. 508). The flute was the favourite instrument in the worship of the goddess. Sacrifices were offered by the people of Celænæ to Marsyas, and he helped them against the Galatians (Paus., x. 30). A statue of Marsyas was erected in the Roman Forum and in other towns, and is said to have been a symbol of liberty.

MARTEN,[1] the name of a group of animals constituting

[1] By all old authors of authority, as Ray, Pennant, Shaw, and Fleming, the word is written "Martin," but this form of spelling is now generally reserved by way of distinction for the bird (see MARTIN). The word, as applied to the animal here described, occurs in most Germanic and Romanic languages:—German, *marder*; Dutch, *marter*; Swedish, *mård*; Danish, *maar*; English, *marteron*, *martern*, *marten*, *martin*, and *martlet*; French, *marte* and *martre*; Italian, *martora* and *martorella*; Spanish and Portuguese, *marta*. Its earliest known use is in the form *martes* (Martial, *Ep.* x. 37), but it can scarcely be an old Latin word, as it is not found in Pliny or other classical writers.

a small but well-defined section of the family *Mustelidæ*, belonging to the Arctoid or Bear-like division of the order *Carnivora* (see MAMMALIA, pp. 439, 440 of the present volume).

The genus *Mustela*, as restricted by Cuvier (*Règne Animal*, 1817), contains a very natural assemblage of animals commonly called Martens, Sables, Polecats, Stoats, Ermines, and Weasels, all closely allied in structure and habits. A structural division, however, occurs between the two first-named and all the others, especially shown in the presence of an additional small premolar tooth on each side of each jaw; and, availing himself of this and some other minor characters, Cuvier divided the genus into two subgenera, for the first of which he retained the name of *Mustela*, and to the second assigned that of *Putorius*. Three years later Nilsson (*Skand. Fauna*, 1820) definitely constituted the two groups into genera, applying to the first the name of *Martes*, by which the animals composing it had been generally designated by the Latin-writing zoologists of the preceding century, and keeping *Mustela* for the more typical Weasels and their immediate allies. Later zoologists have been divided between the nomenclature of Cuvier, which has the priority, and that of Nilsson, which on other grounds is preferable. Those who adopt the latter affirm that Cuvier's names, being only used by him in a subgeneric sense, and not binomially, need not be applied generically; but this is contrary to the practice usually followed in such cases. Others avoid the difficulty by not breaking up the genus at all, and so apply the term *Mustela* to all the species. The result is that the generic name of the Martens in modern zoological works oscillates between *Martes* and *Mustela*, according to the views of the writer.

The following characters apply to the restricted group of Martens proper, by whatever name they are called. Body long, slender, and very flexible, though less so than in the true Weasels. Head somewhat triangular; muzzle pointed, the nose extending a little beyond the lips; eyes large and prominent; ears conspicuous, broad, somewhat triangular, rounded at the ends, furred outside and in; limbs short; feet rounded; toes short, five on each foot, all with short, compressed, curved, sharp-pointed claws. Soles densely furred between the naked pads. Tail moderately long, more or less bushy. Outer fur long, strong, and glossy; a very abundant soft under fur.

Vertebræ: C 7, D 14, L 6, S 3, C 18–23. Skull elongated and depressed. Facial portion moderate and rather compressed. Zygomata arched and wide but slender. Postorbital processes small. Auditory bullæ large, but not very globose. Mandible with a strong triangular vertical coronoid process and a well-developed angular process.

Dentition: $i \frac{3}{3}$, $c \frac{1}{1}$, $p \frac{4}{4}$, $m \frac{1}{2}$; total 38. Upper incisors in a straight transverse line, rather long and compressed; first and second subequal, third considerably larger. Lower incisors very small, especially the first, and crowded together, the second placed rather behind the others. Canines long and sharp-pointed. Upper premolars: first very small, with simple crown and one root; second and third nearly equal in size and two-rooted, with simple compressed sharp-pointed crowns, with very slightly developed accessory cusps; fourth (the sectorial) with blade consisting chiefly of the central and posterior cusps, the anterior being rudimentary, inner tubercle small and confined to the anterior part of the tooth. True molar tubercular, about twice as wide transversely as in the antero-posterior direction, having an outer, more elevated, but smaller portion, bearing three blunt tubercles; to the inner side of this the crown is contracted, and its surface deeply hollowed; it then expands again into a broad low lobe, with the central part elevated, and a raised, even, semicircular, slightly crenated internal border. Lower premolars: first very small, simple, and one-rooted; second, third, and fourth increasing slightly in size, with high compressed pointed crowns and posterior accessory cusps, best marked in the third. First molar (sectorial) with well-marked bilobed blade,—heel scarcely more than one-third of the length of the tooth, and a very small inner tubercle. Second molar small, single-rooted, with a low, flattened, subcircular or oval tubercular crown.

In geographical distribution the Martens are limited to the northern hemisphere, ranging throughout the greater part of the northern temperate regions of both Old and New Worlds, as far north as conditions of existence suited to their habits are met with, and southwards in America to 35° N. lat., while in Asia one species is met with as far as the island of Java.

The various species appear to be very similar in their habits. They live in woods and rocky places, and are thoroughly arboreal, spending most of their time in trees, although descending to the ground in quest of prey. They climb with great facility, and are agile and graceful in their movements. Some species are said occasionally to resort to berries and other fruit for food, but as a rule they are strictly carnivorous, feeding chiefly on birds and their eggs, small mammals, as squirrels, hares, rabbits, and moles, but chiefly mice of various kinds, of which they destroy great numbers, and occasionally snakes, lizards, and frogs. In proportion to their size they are among the most bloodthirsty of animals, though less so than the true Weasels. The female usually makes her nest of moss, dried leaves, and grass in the hollow of a tree, but sometimes in a hole among rocks or ruined buildings, and produces several young at a birth, usually from four to six. Though wild and untameable to a great degree if captured when fully grown, when taken young they are very docile, and have frequently been made pets of, not having the strong unpleasant odour of the smaller *Mustelidæ*. The common European Marten appears to have been partially domesticated by the Greeks and Romans, and to have been used to keep houses clear from rats and mice before cats were introduced.[1] In the same way, according to Hodgson, an allied species, the Yellow-bellied Weasel (*Mustela kathiah*), "is exceedingly prized by the Nepalese for its service in ridding houses of rats. It is easily tamed; and such is the dread of it common to all murine animals that not one will approach a house where it is domiciled." It is, however, to the great value attached to the pelts of these animals that their importance to man is chiefly due. Though all yield fur of serviceable quality, the commercial value varies immensely, not only according to the particular species from which it is obtained, but according to individual variation, depending upon age, sex, season, and other trifling circumstances. The skins from northern regions are more full and of a finer colour and gloss than those from more temperate climates, as are those of animals killed in winter compared to the same individuals in the summer season. The caprices of fashion have, moreover, set wholly factitious values upon slight shades of colour, recognized and named by experienced furriers, but not indicating any specific or other distinctions

and Martial often introduced foreign words into his Latin. Its etymology has been connected with the German "martern," to torment. A second Romanic name for the same animal is *fuina*, in French *fouine* (see E. Von Marten's "Ueber Thiernamen," in *Der Zoologische Garten*, vol. xi., 1870). The term "Marten Cat," often used, is a misnomer, for though somewhat Cat-like in size, general appearance, and habits, its true affinities are not with the *Felidæ*, but, as stated above, with the Bears.

[1] See Rolleston, "On the Domestic Cats, *Felis domesticus* and *Mustela foina*, of Ancient and Modern Times," *Journal of Anatomy and Physiology*, vol. ii. p. 47, 1868.

of which zoologists have any cognizance. Enormous numbers of animals are annually caught, chiefly in traps, to supply the demand of the fur trade, Siberia and North America being the principal localities from which they are obtained.

With the exception of the Pekan (*M. pennanti*) all the Martens are so much alike in size, general colouring, and cranial and dental characters that the discrimination of the species, and assignment of the proper geographical distribution to each, has been a subject which has sorely perplexed the ingenuity and patience of zoologists. The following description by Dr Elliott Coues of the external characters of the American Pine Marten (*M. americana*) will apply almost equally well to most of the others. "It is almost impossible to describe the colour of the Pine Marten, except in general terms, without going into the details of the endless diversities occasioned by age, sex, season, or other incidents. The animal is 'brown,' of a shade from orange or tawny to quite blackish; the tail and feet are ordinarily the darkest, the head lightest, often quite whitish; the ears are usually rimmed with whitish; on the throat there is usually a large tawny-yellowish or orange-brown patch, from the chin to the fore legs, sometimes entire, sometimes broken into a number of smaller, irregular blotches, sometimes wanting, sometimes prolonged on the whole under surface, when the animal is bicolor like a Stoat in summer. The general 'brown' has a greyish cast, as far as the under fur is concerned, and is overlaid with rich lustrous blackish-brown in places where the long bristly hairs prevail. The claws are whitish; the naked nose pad and whiskers are black. The tail occasionally shows interspersed white hairs, or a white tip."

The species generally recognized as distinct are the following, the first five belonging to the Old and the last two to the New World.

1. *Mustela foina*, Erxleben; the Beech Marten, Stone Marten, or White-breasted Marten.—Distinguished from the following by the greater breadth of the skull, and some minute but constant dental characters, by the dull greyish-brown colour of the fur of the upper parts, and the pure white of the throat and breast. It inhabits the greater part of the Continent of Europe, but is more southern than the next in its distribution, not being found in Sweden or Norway, nor, according to the recent investigations of Mr Alston, in the British Isles, although included in their fauna by all earlier writers.

2. *M. martes*, Linn; *Martes sylvatica*, Nilsson; *M. abietum*, Fleming; the Pine Marten (see figure).—Outer fur rich dark brown; under fur reddish-grey, with clear yellow tips; breast spot usually yellow, varying from bright orange to pale cream-colour or yellowish-white. Length of head and body 16 to 18 inches; of tail (including the hair) 9 to 12 inches. This species is extensively distributed throughout northern Europe and Asia, and was formerly

European Pine Marten (*Mustela martes*). From life.

common in most parts of Great Britain and Ireland. Though commonly called "Pine Marten," it does not appear to have any special preference for coniferous trees, except that, inasmuch as they constitute the greater proportion of the forests of the countries which it inhabits, it is more often met with in them than in any other. With regard to its recent occurrence in the British Isles, Mr Alston writes in *Proc. of Zool. Society of London*, 1879:—

"Although greatly reduced in numbers by persecution, it still maintains its ground in the wilder districts of Scotland, the north of England, Wales, and Ireland; and occasionally specimens are killed in counties where the species was thought to have been long extinct. In Scotland it is still found, though comparatively rarely, in the Lews and in most of the Highland mainland counties, being perhaps most abundant in Sutherland and Ross-shire, especially in the deer forests. In the Lowlands a Marten is now a very great rarity; but a fine example was killed in Ayrshire in the winter of 1875–76. In the north of England Mr W. A. Durnford says the species is 'still plentiful' in the wilder parts of Cumberland, Westmoreland, and Lancashire, and in Lincolnshire several have been recorded, the latest killed in 1865, by Mr Cordeaux.[1] In Norfolk one was shot last year; and I have myself examined a fine example which was shot in Hertfordshire, within 20 miles of London, in December 1872. In Dorsetshire the last is said to have been killed in 1804; but a specimen occurred in Hampshire about forty years ago, and another in Surrey in 1847. In Ireland the following counties were enumerated by Thompson as habitats of this species: Donegal, Londonderry, Antrim, Down, Armagh, Fermanagh, Longford, Galway, Tipperary, Cork, and Kerry. The *Cat-crann* is probably now a rarer animal in Ireland than it was when Thompson wrote; but it still exists in various districts, especially in County Kerry, whence the society has received several living examples; and Professor A. Leith Adams states that it has been seen of late years even in county Dublin."

3. *M. zibellina*, Linnæus; the Sable (German, *Zobel* and *Zebel*; Swedish, *sabel*; Russian, *sobol*, a word probably of Turanian origin).—Closely resembling the last, if indeed differing from it except in the quality of the fur, which is the most highly valued of that of all the group. Found chiefly in eastern Siberia.

4. *M. flavigula*, Boddaert; the Indian Marten.—Inhabits the southern slopes of the Himalayas, the Nilgiri Hills, the interior of Ceylon, the Malay Peninsula, and Java.

5. *M. melampus*, Wagner.—Japan.

6. *M. americana*, Turton; the North-American Sable or Marten.—A species so closely allied to the European Pine Marten and Asiatic Sable that it is very difficult to assign constant distinguishing characters between them. The importance of the fur of this animal as an article of commerce may be judged of from the fact that 15,000 skins were sold in one year by the Hudson's Bay Company as long ago as 1743, and the more recent annual imports into Great Britain have exceeded 100,000. It is ordinarily caught in wooden traps of very simple construction, being little enclosures of stakes or brush in which the bait is placed upon a trigger, with a short upright stick supporting a log of wood, which falls upon its victim on the slightest disturbance. A line of such traps, several to a mile, often extends many miles. The bait is any kind of meat, a mouse, squirrel, piece of fish, or bird's head. It is principally trapped during the colder months, from October to April, when the fur is in good condition, as it is nearly valueless during the shedding in summer. Dr Coues tells us that, notwithstanding the persistent and uninterrupted destruction to which the American Sable is subjected, it does not appear to diminish materially in numbers in unsettled parts of the country. It holds its own partly in consequence of its shyness, which keeps it away from the abodes of men, and partly because it is so prolific, bringing forth six to eight young at a litter. Its home is sometimes a den under ground or beneath rocks, but oftener the hollow of a tree, and it is said frequently to take forcible possession of a squirrel's nest, driving off or devouring the rightful proprietor.

7. *M. pennanti*, Erxleben; the Pekan or Pennant's Marten, also called Fisher Marten, though there appears to be nothing in its habits to justify the appellation. This is the largest species of the group, the head and body measuring from 24 to 30 inches, and the tail 14 to 18 inches. It is also more robust in form than the others, its general aspect being more that of a Fox than a Weasel; in fact its usual name among the American hunters is "Black Fox." Its general colour is blackish, lighter by mixture of brown or grey on the head and upper fore part of the body, with no light patch on the throat, and unlike the other Martens generally darker below than above. It was generally distributed in wooded districts throughout the greater part of North America, as far north as Great Slave Lake, lat. 63° N., and Alaska, and extending south to the parallel of 35°; but at the present time it is almost exterminated in the settled parts of the United States east of the Mississippi.

See Elliott Coues, *Fur-bearing Animals, a Monograph of North American Mustelidæ*, 1877; E. R. Alston, "On the British Martens," *Proceedings of the Zoological Society of London*, 1879, p. 468. (W. H. F.)

MARTIAL (M. Valerius Martialis) is a writer to whose merits it is difficult to do justice in the present day. His faults are of the most glaring kind; they are exhibited without the least concealment; and they are of the sort of which modern feeling is most intolerant. Living as he did under perhaps the worst of the many bad emperors who ruled the world in the 1st century, he addresses him and his favourites with the most servile flattery in his lifetime, reviles him immediately after his death (xii. 6), and offers equally fulsome incense at the shrine of his successor. No writer of equal genius has ever shown such an absence of dignity and independence of character in his relation to his richer friends and patrons. He is not ashamed

[1] The *Zoologist* for June 1882 records the recent capture of a Marten in a trap near Bardney in Lincolnshire.

to be dependent on them for gifts of money, for his dinner, and even for his dress. We cannot feel sure that even what seem his sincerest tributes of regard may not be prompted by the hope of payment. Further, there is no book in any literature which, both in expression and in the things treated of, sins so flagrantly against all instincts of propriety. A certain proportion of the epigrams in every book—perhaps one-fifth or one-sixth (in some books the proportion is much larger)—can be read by no class of readers with any other feelings than those of extreme distaste.

These faults are so unmistakable and undeniable that many readers of ancient literature have formed their whole estimate of Martial from them, and have declined to make any further acquaintance with him. Even those who greatly admire his genius, who find the freshest interest in his representation of Roman life and his sketches of manners and character, and who, after admitting the unfavourable first impression which he is bound to make, believe that they still can discern sufficient indications of the better nature which made him a popular and likeable man in his day, do not attempt to palliate his faults, though they may partially account for them by reference to the morals of his age and the circumstances of his life. The time when "the last of the Flavian line was tearing in pieces the half-lifeless world, and Rome was a bond-slave to a bald Nero,"[1] was one when literature had either to be silent or to be servile. Martial was essentially a man of letters; there was no other métier for which he was fitted; he was bound either to gain favour by his writings or to starve. Tacitus and Juvenal might have chosen the latter alternative, but they were fortunately spared the necessity of making the choice by the possession of independent means. Even Statius, the contemporary of Martial, whose writings are in other respects irreproachable, is nearly as fulsome in his adulation as Martial. The relation of client to patron had been recognized as an honourable one by the best Roman traditions. No blame had attached to Virgil or Horace on account of the favours which they received from Augustus and Mæcenas, or of the return which they made for these favours in their verse. That old honourable relationship had, however, greatly changed its character between the era of Augustus and that of Domitian. Men of good birth and education, and sometimes even of high official position (Juv., i. 117), were not ashamed to gain or increase their living by the acceptance of money doles to provide their daily meal. "Atria magna colam" is the resource of a man who was too lazy or too incompetent to become an advocate, and who thought himself too much of a gentleman to adopt any mechanical trade. Martial was merely following a general fashion in paying his court to "a lord." "Rex" is the common term used for a patron. He made the best of the custom. In his earlier career he used to accompany his patrons to their villas at Baiæ or Tibur, and to attend their morning levées. Later on he went to his own small country house, near Nomentum, and sent a poem, or a small volume of his poems, as his representative, at the early visit. If his patron was courteous and liberal, he became his friend and entertained him with his wit and social vivacity. If he was mean and exacting, he found in him a subject for his epigrams. The fault of grossness Martial shares with nearly all ancient and many modern writers who treat of life from the baser or more ridiculous side. That he offends worse than perhaps any of them is to be explained, not, apparently, on the ground that he was more of a libertine in his life, but on the ground that he had to amuse a public which had become more corrupt than in any other civilized era. Although there is the most cynical effrontery and want of self-respect in Martial's use of language, there is not much trace of the satyr in him,—much less, many readers will think, than in Juvenal. Neither is it at all true, as is said by historians of Roman literature (W. S. Teuffel, vol. ii. 317, 5), that his epigrams mostly deal with this side of life. At least four-fifths of them are unexceptionable in subject and treatment.

Our knowledge of Martial's life is derived almost entirely from himself. His writings do not, like those of Horace, supply materials for a continuous biography, nor do they lay bare every secret of his heart with the self-absorption of Catullus. But, as he writes frankly about everything that interested him, he has not only painted a very life-like picture, or rather drawn a multitude of very life-like sketches of Roman society in his time, but he has clearly marked his own position in and his own relation to that society. His criticism of men and manners enables us to judge of the standard which he applied to life, of the things which he liked and disliked, and of his own temper and disposition. Reference to public events enables us approximately to fix the date of the publication of the different books of epigrams, and from these dates to determine those of various important events in his life. Thus, as in book x., which was published in 97 or perhaps 98 A.D., he is found celebrating his fifty-seventh birthday (x. 24), the date of his birth may be assigned to the year 40 or 41. The place of his birth was Bilbilis, or Augusta Bilbilis, in Spain, in a "barren and rugged country" near the sources of the Tagus. His name seems to imply that he was born with the rights of Roman citizenship, but he speaks of himself as "sprung from the Celts and Iberians, and a countryman of the Tagus"; and, in contrasting his own masculine appearance with that of an effeminate Greek, he draws especial attention to "his stiff Spanish hair"—

"Hispanis ego contumax capillis" (x. 65).

In an epigram written nearly thirty years after his removal to Rome he piously commends the soul of a little child, Erotion, to whom he was much attached, to his parents Fronto and Flaccilla, who had gone before to the world of shades (v. 34). Their position in life seems to be indicated by such references to his former home as the phrase "saturæ sordida rura casæ" (x. 96). His home was evidently one of rude comfort and plenty, sufficiently in the country to afford him the amusements of hunting and fishing, which he often recalls with a keen sense of pleasure, and sufficiently near the town to afford him the companionship of many comrades, the few survivors of whom he looks forward to meet again after his five and thirty years absence (x. 104). The memories of this old home, of Bilbilis on its mountain site, of the shallow, rapid Salo flowing round the base of the hill ("fluctu tenui sed inquieto"), of "Gaius hoary with snow and sacred Vadavero with its broken cliffs," of the ilex-grove of Burado (iv. 55) "which even the laziest traveller walks through," and of other spots the rough names and local associations of which he delights to introduce into his verse, attest the enjoyment which he had in his early life, and were among the influences which kept his spirit thoroughly alive in the midst of the deadening routine of social life in Rome. But his Spanish home could impart, not only the vigorous vitality which was one condition of his success as a wit and poet, but the education which made him so accomplished a writer. The literary distinction obtained by the Senecas, by Lucan, by Quintilian, who belonged to a somewhat older generation, and by his friends and contemporaries Licinianus of Bilbilis, Decianus of Emerita, and

[1] Cum iam semianimum laceraret Flavius orbem
Ultimus, et calvo serviret Roma Neroni.—Juv., iv. 37.

Canius of Gades, proves how eagerly the novel impulse of letters was received in Spain in the first century of the empire, just as a similar impulse had been received in Cisalpine Gaul in the first half of the first century before our era. The success of his countrymen may have been the motive which induced Martial's parents to prepare him for a literary career,—

"At me litterulas stulti docuere parentes" (ix. 73, 7),

and which induced Martial himself to remove to Rome when he had completed his education. This he must have done some time before the fall, in 65 A.D., of Seneca and Lucan, who were probably his earliest patrons. He speaks of the halls of the Pisos and of Seneca as having been opened to him when he first went to Rome (iv. 40); and in epigrams, addressed to his widow nearly thirty years after the death of Lucan, he speaks of him with grateful admiration, and applies to her the word "Regina," "his lady patroness."

Of the details of his life for the first twenty years or so after he came to Rome we do not know much. He published some juvenile poems of which he thought very little in his maturer years, and he laughs at a foolish bookseller who would not allow them to die a natural death (i. 113). Martial had neither youthful passion nor youthful enthusiasm to make him precociously a poet. His faculty ripened with experience and with the knowledge of that social life which was both his theme and his inspiration; and many of his best epigrams are among those written in his last years. From many answers which he makes to the remonstrances of friends,—among others to those of Quintilian,—it may be inferred that he was urged to practise at the bar, but that he preferred his own lazy Bohemian kind of life to more settled and remunerative modes of industry. He made many influential friends and patrons, and secured the favour both of Titus and Domitian. From them he obtained various privileges, among others the "semestris tribunatus," which conferred on him equestrian rank. He failed, however, in his application to the latter for more substantial advantages, although he commemorates the glory of having been invited to dinner by him, and also the fact that he procured the privilege of citizenship for many persons in whose behalf he appealed to him. The earliest of his extant works, that known by the name of *Liber Spectaculorum*, was first published at the opening of the Colosseum in the reign of Titus; but the book as it now stands was given to the world in or about the first year of Domitian, *i.e.*, about 81 A.D. The favour of the emperor procured him the countenance of some of the worst creatures at the imperial court,—among them of the notorious Crispinus, of Parthenius, Earinus, Regulus, and probably of Paris, the supposed author of Juvenal's exile, on whose death Martial afterwards wrote a eulogistic epitaph. The two books numbered xiii. and xiv., and known by the name of *Xenia* and *Apophoreta*,—inscriptions of two lines for presents,—were published between 81 and 86 A.D. In that last year he gave to the world the first two of the twelve books on which his reputation rests. From that time till his return to Spain in 98 A.D. he published a volume almost every year. The first nine books and the first edition of book x. appeared in the reign of Domitian; and book xi. at the end of 96 A.D., shortly after the accession of Nerva. A revised edition of book x., that which we now possess, appeared in 98 A.D., about the time of the entrance of Trajan into Rome. The last book was written after three years' absence in Spain, shortly before his death, which happened about the year 102 or 103 A.D.

These twelve books bring Martial's ordinary mode of life between the age of five-and-forty and sixty very fully before us. His regular home for five-and-thirty years was Rome. He lived at first up three pair of stairs ("et scalis habito tribus sed altis," i. 117), and his rooms overlooked the laurels in front of the portico of Agrippa. He had a small and not very valuable country house near Nomentum, in the Sabine territory, to which he occasionally retired as a refuge from the bores and noises of the city (ii. 38, xii. 57). In his later years he had a small house on the Quirinal, near the temple of Quirinus. At the time when his third book was brought out he had retired for a short time to Cisalpine Gaul, in weariness, as he tells us, of his unremunerative attendance on the levées of the great—

"Non poterat vanæ tædia ferre togæ" (iii. 4).

For a time he seems to have felt the charm of the new scenes which he visited, and in a later book (iv. 25) he contemplates, probably with a reminiscence of Horace (*Od.* ii. 6), the prospect of retiring to the neighbourhood of Aquileia and the Timavus in his old age. But the spell exercised over him by Rome and Roman society was too great to permit of a prolonged absence; and even the epigrams sent from Forum Corneli and the Æmilian Way ring much more of the Roman Forum, and of the streets, baths, porticos, and clubs of Rome, than of the places from which they are dated. So too his motive for his final departure from Rome in 98 A.D. was a weariness of the burdens imposed on him by his social position, and, apparently, the difficulties of meeting the ordinary expenses of living in the metropolis (x. 96); and he looks forward, with a kind of "nostalgia," to a return to the scenes familiar to his youth. The well-known epigram addressed to Juvenal (xii. 18) shows that for a time his ideal was realized; but the more trustworthy evidence of the prose epistle prefixed to book xii. proves that his contentment was of very short duration, and that he could not live happily away from the literary and social pleasures of Rome ("bibliothecas, theatra, convictus"), which supplied both the impulse to his genius and the material on which it could exercise itself. The one consolation of his exile was the society of a lady, Marcella, of whom he writes rather as if she were his patroness,—and it seems to have been a necessity of his being to have always a patron or patroness,—than his wife or mistress. His delight in her society arose from his finding in her one who, though born and bred in this remote province, yet by her natural grace and accomplishment revived for him the charm of Rome.

During his life there, although he never rose to a position of real independence, and had always a hard struggle with poverty, he seems to have known everybody, especially every one of any eminence at the bar or in literature. In addition to Lucan and Quintilian, he numbered among his friends or more intimate acquaintances Silius Italicus, Juvenal, the younger Pliny; and we find a number of other names, such as those of Julius Martialis, Faustinus, Bassus, Decianus, Melior, Stella, &c., of men holding a high social, legal, or literary position, whose society and patronage he enjoyed. The silence which he and Statius, although authors writing at the same time, having common friends, and treating sometimes of the same subjects, maintain in regard to one another may be explained by mutual dislike or want of sympathy. Martial, in many places, shows an undisguised contempt for the artificial kind of epic on which Statius's reputation chiefly rests; and it seems quite natural that the respectable author of the *Thebaid* and the *Silvæ* should feel little admiration for either the life or the works of the Bohemian epigrammatist.

The personal faults of Martial, which deny to his

writings, notwithstanding their vivacity, truth, and brilliancy, a place among the best poetry of antiquity, have been sufficiently indicated. It remains to ask, What were those qualities of nature and intellect which enable us to read his best work—even the great body of his work—with the freshest sense of pleasure in the present day?

He had the keenest capacity for enjoyment, the keenest curiosity and power of observation. The ordinary spectacle of Roman life, as it passed before his eyes, was thus vividly apprehended and reproduced by him in all its details; and the many varieties of character which an over-ripe and decaying civilization produces were quickly seized and graphically sketched. He had also a very just discernment. It is rare to find any one endowed with so quick a perception of the ridiculous who is so little of a caricaturist. He was himself singularly free from cant, pedantry, or affectation of any kind. Though tolerant of most vices, he has a hearty scorn of hypocrisy,—of the combination of outward austerity with secret profligacy,—of the man who, while he wears

"Fuscos colores, galbinos habet mores."[1]

There are few better satirists of social and literary pretenders either in ancient or modern times. Living in a very artificial age, he was quite natural, hating pomp and show, and desiring to secure in life only what really gave him pleasure. To live one's own life heartily from day to day without looking before or after, and to be one's self without trying to be that for which nature did not intend him, is the sum of his philosophy. It is the philosophy of a man who has passed the middle of life, who has outlived any illusions he may ever have had, and who is quite content that whatever remains to him in the future should be like his present. Further, while tolerant of much that is bad and base,—the characters of Crispinus and Regulus, for instance,—he shows himself genuinely grateful for kindness and appreciative of excellence. He has no bitterness, malice, or envy in his composition. He professes to avoid personalities in his satire;—"Ludimus innocui" is the character he claims for it. Pliny, in ths ehort tribute which he pays to him on hearing of his death, says, "He had as much candour as wit and pungency in his writings" (*Ep.* iii. 21).

Honour and sincerity (*fides* and *simplicitas*) are the qualities which he most admires in his friends. Though many of his epigrams indicate a cynical disbelief in the character of women, yet others prove that he could respect and almost reverence a refined and courteous lady. His own life in Rome afforded him no experience of domestic virtue; but his epigrams show that, even in the age which is known to modern readers chiefly from the *Satires* of Juvenal, that virtue was recognized as the purest source of happiness. The tenderest element in Martial's nature seems, however, to have been his affection for children and for his dependants. The pathos with which he has recorded their premature death, combined with his fresh enjoyment of outward nature, give to many of his pieces a rank among the serious poetry of the world—"inter sanctiora carmina,"—to use a phrase of his own.

The permanent literary interest of Martial's epigrams arises not so much from their verbal point or brilliancy, though in these respects they are unsurpassed, as from the amount of human life and character which they contain. There is no truer painter of social manners in antiquity. He enables us better than any other writer to revive the outward spectacle of the imperial Rome which we see in its ruins, and to repeople its streets, shops, porticos, baths, and amphitheatres. If Juvenal enforces the lesson of that time, and has penetrated more deeply into the heart of society, Martial has sketched its external aspect with a much fairer pencil and from a much more intimate contact with it. It is from the immediate impressions and comments of the epigrammatist that the satirist has taken the suggestion of many of his more elaborate pictures and more stern denunciations. But it is not only the peculiarities of Roman customs that live in the writings of Martial. His page, to use his own phrase, "has the true relish of human life" in every age—"hominem pagina nostra sapit." He was to Rome in the decay of its ancient virtue and patriotism what Menander was to Athens in its decline. They were both men of cosmopolitan rather than of a national type, and had a closer affinity to the life of Paris or London in the 18th century than to that of Rome in the days of the Scipios or of Athens in the age of Pericles. The form of epigram was fitted to the critical temper of Rome as the comedy of manners was fitted to the dramatic genius of Greece. Martial professes to be of the school of Catullus, Pedo, and Marsus, and admits his inferiority only to the first. But, though he is a poet of a less pure and genuine inspiration, he is a greater epigrammatist even than his master. He has indeed made that form of art peculiarly his own. He has applied it to the representation of a very much greater number of situations, incidents, and characters, and he has done this with the greatest clearness, terseness, and vivacity of style, and with a masterly command over all his metres, except the pure hexameter, in which no other writer has been able to treat the familiar matters of the day with the light touch of Horace. Martial, except where he is flattering the emperor,—and then we may sometimes suspect an undercurrent of irony,—is one of the most natural and sensible as he is one of the wittiest and most brilliant of writers. He fails, perhaps, more often in his wit than in his sense. He is full of the happiest phrases, which express admirably for all times, without over-subtlety and without triteness, the judgment and impressions of life formed by direct contact with it, and taken neither from books nor from the opinions of other men, of a thorough man of the world, who had yet some feelings and sensibilities to which men of the world are generally strangers. He wrote naturally because he was completely in harmony with the life of his age. As this is the explanation of his grave offences, it should also be recognized as contributing to his merits as a writer.

Owing probably to the reasons which have excluded his writings from school education, little has been done for the criticism or explanation of Martial for about two centuries. There is a good edition of the text by Schneidewin in the Teubner series of classics. For English readers the *Selected Epigrams of Martial*, by H. H. Stephenson, and the *Martialis Epigrammata Selecta*, by Messrs Paley and Stone, may be recommended as a good introduction to the study of this poet. An edition of book i., with a Latin commentary by J. Flach, has lately appeared at Tübingen. Further information about him may be obtained in a work by A. Brandt, *De Martialis poetæ vita et scriptis* (Berlin, 1853), and in Friedländer's *Sittengeschichte Roms*; and an excellent criticism on his writings is to be found among the prose works of Lessing. (W. Y. S.)

MARTIAL LAW. See MILITARY LAW.

MARTIGUES, chief place of a canton in the department of Bouches-du-Rhône, France, stands on the southern shore of the lagoon of Berre, and at the eastern extremity of that of Caronte, by which the former is connected with the Mediterranean. Divided into three quarters by canals with numerous bridges, the place has sometimes been called the Venice of Provence. It has a harbour of 10 acres, an iron foundry, workshops for maritime constructions, oil manufactures, and chemical works; the principal industry, however, consists in the preparation of "boutargue," which is obtained from the roes of the grey mullet caught in the lagoons, and rivals Russian caviare. The population in 1876 was 8053.

[1] "Whose dress is of a dull colour, his morals a pale green."

Built in 1232 by Raymond Bérenger, count of Provence, Martigues was made a viscountship by Joanna I., queen of Naples. Henry IV. made it a principality, in favour of a princess of the house of Luxembourg. It afterwards passed into the hands of the duke of Villars.

MARTIN [1] (French, *Martinet*), the *Hirundo urbica* of Linnæus and *Chelidon urbica* of modern ornithologists, a bird very well known throughout Europe, including even Lapland, where it is abundant, retiring in winter to the south of Africa.[2] It also inhabits the western part of Asia, and appears from time to time in large flocks in India; but the boundaries of its range and those of at least one of its Eastern congeners cannot as yet be laid down. The Martin (or House-Martin, as it is often called, to distinguish it from the Sand-Martin presently to be mentioned) commonly reaches its summer-quarters a few days later than the SWALLOW (*q.v.*), whose habits its own so much resemble that heedless persons often disregard the very perceptible differences between them, the Martin's white rump and lower parts being conspicuous as it flies or clings to its "loved mansionry" attached to our houses, for, as Shakespeare wrote—

> "No jutty, frieze,
> Buttress, nor coign of vantage, but this bird
> Hath made his pendent bed and procreant cradle."
> —*Macbeth*, act i. sc. 6.

This nest, made of the same material as the Swallow's, is, however, a far more difficult structure to rear, and a week or more is often occupied in laying its foundations—the builders clinging to the wall while depositing the mud of which it is composed. But, the base once securely fixed, the superstructure is often quickly added till the whole takes the shape of the half or quarter of a hemisphere, and a lining of soft feathers, mixed with a few bents or straws, fits it for its purpose. The Martin sets about building very soon after its return, and a nest that has outlasted the winter's storms is almost at once reoccupied; though if a new nest be needed its construction often involves great delay, for any excess of wet or drought retards the operation, and the work is generally placed in such an exposed situation that heavy driving rains will frequently wash away the half-dried walls. However, the bird mostly perseveres against these and other untowardnesses, contriving in the course of the summer to raise a second or, rarely, a third brood of offspring—though it is certain that the latest broods often die in the nest—apparently through failure of food. Yet what seem to be adults of this species are observed in England every year so late as November, and there are several instances of its appearance within a few days of the winter solstice; but it is to be remarked that these late birds are almost certainly strangers, and not natives of the locality in which they are seen.

The Sand-Martin, *Hirundo riparia* of Linnæus and *Cotile riparia* of modern writers, differs much in appearance and habits from the former. Its smaller size, mouse-coloured upper surface, and jerking flight ought to render it easily recognizable from the other British *Hirundinidæ*; but through carelessness it is seldom discriminated, and, being the first of the Family to return to its northern home, the "early Swallow" of newspaper-writers would seem to be nearly always of this species. Instead of the clay-built nest of the House-Martin, this bird bores, with a degree of regularity and an amount of labour rarely excelled in its Class, horizontal galleries in a natural or artificial escarpment. When beginning its excavation, it clings to the face of the bank, and with its bill loosens the earth, working from the centre outwards, assuming all sorts of positions—as often as not hanging head downwards. The form of the boring and its length depend much on the nature of the soil; but the tunnel may extend to 4, 6, or even 9 feet. The gallery seems intended to be straight, but inequalities of the ground, and especially the meeting with stones, often cause it to take a sinuous course. At the end is formed a convenient chamber lined with a few grass stalks and feathers, the latter always beautifully arranged, and upon them the eggs are laid. The Sand-Martin has several broods in the year, and is much more regular than other *Hirundinidæ* in its departure for the south. The kind of soil needed for its nesting-habits makes it a somewhat local bird; but no species of the Order *Passeres* has a geographical range that can compare with this. In Europe it is found nearly to the North Cape, and thence to the Sea of Okhotsk. In winter it visits many parts of India, and South Africa to the Transvaal territory. In America its range is even more extraordinary, extending (due regard being of course had to the season of the year) from Melville Island to Caiçara in Brazil, and from Newfoundland to Alaska.

The Purple Martin of America,[3] *Hirundo* or *Progne purpurea*, requires some remarks as being such a favourite bird in Canada and in the United States. Naturally breeding in hollow trees, it readily adapts itself to the nest-boxes which are very commonly set up for its accommodation; but its numbers are in some years and places subject to diminution in a manner which has not yet been satisfactorily explained. The limits of its range in winter are not determined, chiefly owing to the differences of opinion as to the validity of certain supposed kindred species found in South America; but according to some authorities it reaches the border of Patagonia, while in summer it is known to inhabit lands within the Arctic Circle. The male is almost wholly of a glossy steel-blue, while the female is much duller in colour above, and beneath of a brownish-grey.

Birds that may be called Martins [4] occur almost all over the world except in New Zealand, which is not regularly inhabited by any member of the Family. The ordinary Martin of Australia is the *Hirundo* or *Hylochelidon nigricans* of most ornithologists, and another and more beautiful form is the Ariel or Fairy-Martin of the same country, *Hirundo* or *Lagenoplastes ariel*. This last builds of mud a bottle-shaped nest, as does also the Rock-Martin of Europe, *Hirundo* or *Biblis rupestris*; but space fails wherein to tell more of these interesting birds. (A. N.)

MARTIN, ST, bishop of Tours, was born of heathen parents at Sabaria (*Stein am Anger*) in Pannonia, about the year 316. When ten years of age he became a catechumen, and at fifteen, contrary to his own inclination, he entered the army. It was while he was stationed at Amiens that he divided his cloak with the beggar, and on the following night had the vision of Christ making known to his angels this act of charity to Himself on the part of "Martinus, still a catechumen." Soon afterwards he received baptism, and, two years later, having been permitted to leave the army, he joined Hilary of Poitiers, who wished to make him a deacon, but at his own request ordained him to the humbler office of an exorcist. In the course of the years that followed he undertook a journey to Pannonia for the purpose of converting his parents, and was successful in bringing his mother within the pale of

[1] The older English form, Martlet (French, *Martelet*), is, except in heralds' language, almost obsolete, and when used is now applied in some places to the SWIFT (*q.v.*).

[2] Since the publication of the account of this species in Yarrell's *British Birds* (ed. 4, ii. p. 354), Mr Gurney has informed the writer of a specimen obtained out of a migratory flock flying very high on the Qua'qua' river, lat. 19° 10′ S., by the expedition of Messrs Jameson and Ayres, 23d October 1880.

[3] In 1840 an example is said to have been killed at Kingstown in Ireland, the skin of which is in the Dublin Museum of Science and Art.

[4] The *Martin* of French colonists (in the Old World) is an *Acridotheres*, one of the STARLINGS (*q.v.*).

the church. For some time, doubtless during the Arian troubles, he lived, along with a presbyter friend, an ascetic life on the desert island of Gallinaria near Genoa; in 360 he was again with Hilary at Poitiers, and founded in the neighbourhood the monasterium Locociagense (Licugé). Here his miracles, which included more than one case of restoring the dead to life, were very numerous, and made him so famous that in 371 the people of Tours insisted on having him for their bishop. In this capacity he was extremely zealous and energetic in seeking to extirpate idolatry from his diocese and from France, and by example as well as by precept he did much for the spread of the monastic system. To obtain the privacy that he required for the maintenance of his personal religion, he established the monastery of Marmoutier-les-Tours (Martini monasterium) on the banks of the Loire. At Treves, in 385, he was importunate in his entreaties that the lives of the Priscillianist heretics should be given them, and he ever afterwards refused to hold ecclesiastical fellowship with those bishops who had sanctioned their execution. He died at Candes about the year 400, and is commemorated by the Roman Church on November 11 (duplex). He is the patron saint of France, and of the cities of Mainz and Würzburg. The *Life* by his disciple Sulpicius Severus is practically the only source we have for his biography, but it is full of legendary matter and chronological inaccuracies. The feast of St Martin (Martinmas) took the place of an old pagan festival, and inherited some of its usages (such as the Martinsmännchen, Martinsfeuer, Martinshorn, and the like, in various parts of Germany); by this circumstance is most probably to be explained the fact that he is regarded as the patron of drinking and jovial meetings, as well as of reformed drunkards.

MARTIN I., pope, succeeded Theodore I., in June or July 649. He had previously acted as papal apocrisiarius at Constantinople, and was held in high repute for learning and virtue. Almost his first official act was to summon a synod (the first Lateran) for dealing with the Monothelite heresy. It met in the Lateran church, was attended by one hundred and five bishops (chiefly from Italy, Sicily, and Sardinia, a few being from Africa and other quarters), held five sessions or "secretarii" from the 5th to the 31st of October 649, and in twenty canons condemned the Monothelite heresy, its authors, and the writings by which it had been promulgated. In this condemnation were included, not only the "Ecthesis" or exposition of faith of the patriarch Sergius for which the emperor Heraclius had stood sponsor, but also the "Typus" of Paul, the successor of Sergius, which had the support of the reigning emperor (Constans II.). Martin was very energetic in publishing the decrees of his Lateran synod in an encyclical, and Constans replied by enjoining his exarch to seize the pope, should he persist in this line of conduct, and send him prisoner to Constantinople. These orders were found impossible of execution for a considerable space of time, but at last Martin was arrested in the Lateran (June 15, 653), hurried out of Rome, and conveyed first to Naxos and subsequently to Constantinople (September 17, 654). After suffering an exhausting imprisonment and many public indignities, he was ultimately banished to Cherson, where he arrived on March 26, 655, and died on the 16th of September following. His successor was Eugenius I. A full account of the events of his pontificate will be found in Hefele's *Conciliengeschichte*, vol. iii., 1877.

MARTIN II. See MARINUS I.

MARTIN III. See MARINUS II.

MARTIN IV., pope from 1281 to 1285, was the successor of Nicholas III. He was a native of Touraine, born about 1210, and his proper name was Simon de Brion. After holding various offices at Rouen and Tours, he was made chancellor of France by Louis IX. in 1260, and cardinal by Urban IV. in 1261. He acted as legate for this pope and also for his successor Clement IV. in the negotiations for the assumption of the crown of Sicily by Charles of Anjou, and he is supposed also to have stimulated the ambition of Philip III. for the imperial dignity in 1273. After the death of Nicholas III. (August 1280) Charles of Anjou was able to secure the election of Cardinal Simon by the conclave at Viterbo (February 22, 1281). The Romans declined to receive him within their walls, and he was crowned at Orvieto. At the instance of Charles, whose tool he had become, he in November 1281 excommunicated the emperor Michael Palæologus, who stood in the way of the French projects against Greece,—an act by which the union of the Eastern and Western churches was rendered impossible. For three years after the Sicilian Vespers in 1282 all the spiritual and material resources at his command were in vain employed on behalf of his patron against Peter of Aragon. He died at Perugia on March 25, 1285, and was succeeded by Honorius IV.

MARTIN V. (Otto di Colonna), pope from 1417 to 1431, was elected on St Martin's day at Constance by a conclave consisting of twenty-three cardinals and thirty delegates of the council, which after deposing John XXIII. had long experienced much perplexity from the conflicting claims of Gregory XII. and Benedict XIII. The son of Agapito Colonna and Catarina Conti, born about 1368, he belonged to one of the oldest and most distinguished families of Rome, became apostolic protonotary under Urban VI., was created cardinal-deacon by Innocent VII., and in 1410 was the delegate of Alexander V. to hear the appeal which had been taken in that year to the papal see by John Huss. He was justly esteemed for his moderation, learning, uprightness, and business capacity, but he failed to achieve, as he might have done, the honour of being a reforming pope. His first act after his election was to publish a brief confirming all the regulations made by his predecessors with regard to the papal chancery,—regulations which had long been the subject of just complaint. When the "nations" of the council pressed their plans for reform, Martin submitted a counter scheme, and ultimately entered into negotiations for separate concordats, for the most part vague and illusory, with Germany, England, and France. He left Constance at the close of the council (May 1418), but travelled slowly through Italy, lingered at Florence, and did not venture to enter Rome until September 1420, when his first task was to seek to restore it to the prosperity and order to which it had become a stranger. In accordance with the decree of Constance, confirmed by himself, ordering that councils should be held every five years, he in 1423 summoned the council which met at Pavia and afterwards at Siena; it was somewhat poorly attended, and this circumstance gave the pope a pretext for dissolving it as soon as it had come to the resolution that "internal church union by reform ought to take precedence of external union." It was prorogued for seven years, and then met at Basel; shortly after its opening Martin died of apoplexy, on February 20, 1431. His successor was Eugenius IV.

MARTIN, JOHN (1789–1854), a popular English painter, was born at Haydon Bridge, near Hexham, on the 19th of July 1789. On account of his early interest in art he was apprenticed by his father to a coachbuilder to learn heraldic painting, but owing to a quarrel the indentures were cancelled, and he was placed under Bonifacio Musso, an Italian artist, father of the well-known enamel painter Charles Musso. With his master Martin removed to London in 1806, where he married at the age of nineteen, and led a struggling life, supporting himself by giving drawing lessons, and by painting in

water colours, and on china and glass. His leisure was occupied in the study of perspective and architecture. His first picture, Sadak in Search of the Waters of Oblivion, was executed in a month. It was exhibited in the Royal Academy of 1812, and sold for fifty guineas. It was followed by the Expulsion (1813), Paradise (1813), Clytie (1814), and Joshua (1815). In 1821 appeared the famous Belshazzar's Feast, which excited much favourable and hostile comment, and was awarded a prize of £200 at the British Institution, where the Joshua had previously carried off a premium of £100. Then came the Destruction of Herculaneum (1822), the Creation (1824), the Eve of the Deluge (1841), and a long series of other Biblical and imaginative subjects, many of which are widely known through engravings. In 1832–33 Martin received £2000 for drawing and engraving a fine series of designs to Milton, and along with Westall he produced a set of Bible illustrations. He was also much occupied with schemes for the improvement of London, and published various pamphlets and plans dealing with the metropolitan water supply, sewage, dock, and railway systems. During the last four years of his life he was engaged upon his large subjects of the Judgment, the Day of Wrath, and the Plains of Heaven. He was attacked with paralysis while painting, and died in the Isle of Man on the 17th of February 1854.

The bold originality of Martin's productions startled and attracted the public, but they are without the qualities of solid execution and truth to nature upon which a lasting fame in the arts must be built. His figures are badly drawn, his colouring is hot and unpleasant. To most of his professional brethren his works seemed theatrical and tricky; and the best lay critics of his time, like Charles Lamb, were disposed to deny that they evinced true imaginative power. His popularity may be said to have culminated in 1828, the year of his Fall of Nineveh; since then it has been gradually declining.

MARTINA FRANCA, a city of Italy in the province of Lecce, 18 miles north of Taranto, on a hill near the sources of the Tara. It was a fief of the Caraccioli family, and dates from a comparatively modern epoch. The ducal palace is one of the finest buildings of its kind in the south of Italy, somewhat similar in style of architecture to the Palazzo Pamfili in Naples. The population of the city was 13,088 in 1861; that of the commune has increased from 16,637 in that year to 19,257 in 1881.

MARTINEAU, Harriet (1802–1876), English woman of letters, was born at Norwich, where her father was a manufacturer. The family was of Huguenot extraction, but had adopted Unitarian views. Her education, which included Latin and French, as well as domestic accomplishments, was received partly at home, and partly under a Mr Perry, to whose lessons in logical English composition she ascribed something of her later clearness of thought and statement. The atmosphere of her home was industrious, intellectual, and austere; she herself was clever, weakly, and unhappy, and was, moreover, already growing deaf. At the age of fifteen the state of her health and temper led to a prolonged visit to her father's sister, Mrs Kentish, who kept a school at Bristol. Here, in the companionship of amiable and talented people, her life became happier. Here, also, she fell under the influence of the Unitarian minister, Dr Carpenter, from whose instructions, she says, she derived "an abominable spiritual rigidity and a truly respectable force of conscience strangely mingled together." From 1819 to 1830 she again resided chiefly at Norwich. The first part of this period was mainly spent in quiet and almost secret study and in needlework. About her twentieth year her deafness became confirmed, and she habitually from that time used an ear trumpet. In 1821 she began to write anonymously for the *Monthly Repository*, a Unitarian periodical, and was assured by her brother that authorship was her proper career. A little later she published *Devotional Exercises and Addresses, Prayers, and Hymns.*

In 1826 her father died, leaving a bare maintenance to his wife and daughters. His death had been preceded by that of his eldest son, and was shortly followed by that of the young man to whom Harriet was engaged. Mrs Martineau and her daughters soon after lost all their means by the failure of the house where their money was placed. Harriet had to earn her living, and, being precluded by her deafness from teaching, took up authorship in earnest and toiled with incredible industry. She reviewed for the *Repository* at the rate of £15 a year, wrote stories (afterwards collected as *Traditions of Palestine*), gained in one year (1830) three essay-prizes of the Unitarian Association, and eked out her income by needlework. In 1831 she was seeking a publisher for a series of tales designed as *Illustrations of Political Economy.* After many failures she accepted very disadvantageous terms, and the first number appeared amidst gloomy prognostications from the publisher. The sale, however, was immediate and enormous, the demand increased with each new number, and from that time her literary success was secured. In 1832 she moved to London; she at once became the fashion, and her acquaintance was eagerly sought. Till 1834 she continued to be occupied with her political economy series and with a supplemental series of *Illustrations of Taxation.* Four stories dealing with the poor-law came out about the same time. These tales, direct, lucid, written without any appearance of effort, and yet practically effective, display the characteristic qualities of their author's style. In 1834, when the whole series was complete, Miss Martineau paid a long visit to America. Here her open adhesion to the Abolitionist party, then small and very unpopular, gave great offence; which was deepened by the publication, soon after her return, of *Society in America* and a *Retrospect of Western Travel.* An article in the *Westminister Review*, "The Martyr Age of the United States," introduced English readers almost for the first time to the struggles of the Abolitionists. In these American writings Miss Martineau shows less than her usual calmness and judicial common sense, but it will scarcely be denied that there was some ground for her vehemence. The American books were followed by a novel, *Deerbrook*,—a story of middle class country life, lacking the delicate humour of Miss Austen or the touch of farce that enlivens Miss Edgeworth's tales, but delightfully clear in style, wholesome in spirit, and well sustained in point of interest. To the same period belong two or three little handbooks, forming parts of a *Guide to Service.* The veracity of her *Maid of all Work* led to a widespread belief, which she regarded with some complacency, that she had once been a maid of all work herself.

In 1839, during a visit to the Continent, Miss Martineau's health, which had long been bad, broke down entirely. She retired to solitary lodgings in Tynemouth, and remained a prisoner to her couch till 1844. She was still busy, and, besides a novel (*The Hour and the Man*), published some tales for children, and *Life in the Sick-room.* These volumes contain some of her best work, and possess a charm of tender feeling to balance the somewhat cold rationality that predominates in most of Miss Martineau's writing. During this illness she for a second time declined a pension on the civil list, fearing to compromise her political independence. Her letter on the subject was published, and some of her friends raised a small annuity for her soon after.

In 1844 Miss Martineau underwent a course of mesmerism, and in a few months was restored to health. Her recovery excited much discussion and controversy.

She herself felt no doubt either of its reality or of its being due to mesmerism, and not unnaturally resented the incredulity of others. She eventually published an account of her case in sixteen *Letters on Mesmerism*, a proceeding which caused great offence to some members of her family. On finding herself set free from the bondage of ill-health, she removed to Ambleside, where she built herself the house in which the greater part of her after life was spent. In 1845 she published three volumes of *Forest and Game Law Tales*, in which the method of her political economy series was again applied. In 1846 she made an Eastern tour with some friends. She was abroad for eight months, visiting Egypt, Palestine, and Syria, and on her return published *Eastern Life*. The tendency of this work is to display humanity passing through one after another of the world's historic religions, the conception of the Deity and of Divine government becoming at each step more and more abstract and indefinite. The ultimate goal Miss Martineau believed to be a philosophic atheism, but this belief she did not expressly declare in *Eastern Life*, considering it to be outside the province of that book. She published about this time *Household Education*, expounding the modern theory, in which freedom and rationality, rather than command and obedience, are regarded as the most effectual instruments of education. Her practical interest in all schemes of instruction led her to start a series of lectures, addressed at first to the school children of Ambleside, but afterwards extended, at their own desire, to their elders. The subjects of these lectures were sanitary principles and practice, the histories of England and North America, and the scenes of her Eastern travels. At the request of Mr Charles Knight she wrote for him, in 1849, *The History of the Thirty Years' Peace*,—a characteristic instance of Miss Martineau's remarkable powers of labour. "From the first opening of the books to study for the history to the depositing of the MS. of the first volume at press was," she says, "exactly six months. The second volume took six months to do."

In 1851 Miss Martineau edited a volume of *Letters on the Laws of Man's Nature and Development*. Its form is that of a correspondence between herself and Mr H. G. Atkinson (in which the latter has much the larger share), and it expounds that doctrine of philosophical atheism to which Miss Martineau had, in *Eastern Life*, depicted the course of human belief as tending. The existence of a first cause is not denied, but is declared unknowable, and the authors, while regarded by others as denying it, certainly considered themselves to be affirming the doctrine of man's moral obligation. Mr Atkinson was a zealous exponent of mesmerism, and the prominence given to the topics of mesmerism and clairvoyance no doubt tended to heighten the disapprobation with which the book was received. The reviewers were almost unanimous in condemnation, and the publication caused a lasting division between Miss Martineau and some of her friends.

The new philosophical bent of her studies directed Miss Martineau's attention to the works of Comte, and she undertook a condensed English version of the *Philosophie Positive*. It appeared in 1853, and to most readers is more useful and intelligible than the original. She had begun in the previous year to write articles, chiefly biographical, for the *Daily News*. Among these were the *Letters from Ireland*, written during a visit to that country in the summer of 1852. She also wrote a considerable number of essays upon different manufactures for *Household Words*, and another series for the same periodical upon the treatment of blindness, deafness, idiotcy, &c., besides a *Guide to Windermere*, followed afterwards by a *Complete Guide to the Lakes*. She had been for many years a contributor to the *Westminister Review*, and was one of the little band of supporters whose pecuniary assistance, in 1854, prevented its extinction or forced sale. In the early part of 1855 Miss Martineau found herself suffering from heart disease. Having always felt it one of her duties to write her autobiography, and believing the time before her to be but brief, she now at once set about this task, and on its completion caused the book to be printed that it might be ready for speedy publication at her death. But her life, which she supposed to be so near its close, was prolonged for other twenty years, her death not taking place until 1876.

These years were by no means idle. She continued to contribute to the *Daily News*, for which she wrote in all more than 1600 articles, and to the *Westminster Review*, as well as to other papers, and her biographical sketches were collected and reprinted from the *Daily News* in a volume which has justly become one of the best-known of her works. In point of style it is probably the most excellent of them all. The form and method leave nothing to be desired, and the perception of character is shrewd, sincere, and, roughly speaking, reliable. But in reading the book we feel that the biographies, divided by the editor into groups of royal, political, &c., fall far more naturally into two larger classes,—the biographies of persons whom Miss Martineau liked, and the biographies of persons whom she disliked. All are doubtless in a sense true, as all photographs are true, but the difference between a flattering and an unflattering photograph is considerable.

She also produced two books on the government of India, and was continually occupied in promoting schemes of reform and benevolence. Her poorer neighbours owed much to her kindly and enlightened efforts, and her servants found in her a friend as well as a mistress. Her long and busy life bears the consistent impress of two leading characteristics,—industry and sincerity. Her work was invariably sound, and its motive invariably respectable. The verdict which she records on herself in the autobiographical sketch left to be published by the *Daily News* is probably very near to that which will be recorded by future judgment. She says,—"Her original power was nothing more than was due to earnestness and intellectual clearness within a certain range. With small imaginative and suggestive powers, and therefore nothing approaching to genius, she could see clearly what she did see, and give a clear expression to what she had to say. In short, she could popularize while she could neither discover nor invent." Her judgment on large questions was clear and sound, and was always the judgment of a mind naturally progressive and Protestant. Mentally she was a true daughter of her Huguenot ancestors. But it is impossible to read her autobiography without suspecting that she was subject to considerable prejudices, especially in her judgment of persons, and that her temper, particularly in earlier life, was unamiable, hard, and unforgiving. She seems, indeed, to have possessed the sort of disposition which shows to much greater advantage in its relation to juniors, inferiors, and dependants than in its relations to elders and superiors, and which therefore appears more amiable in the closing than in the opening years of life. Her autobiography reveals also a weakness which was perhaps unavoidable. The publication of her political economy tales brought her into great and sudden notice; many persons of high position, official and otherwise, desired to enlist her advocacy on the part of their particular projects. She found her help much courted, and much help eagerly proffered to her. Her deafness, which suffered her to hear only what was directly addressed to herself, assisted to make her a central figure, and to induce the belief that hers was one of the most potent if not actually the most potent voice in English politics. Her deafness was in another direction probably advantageous. It led her to find solitude easier than most companionship, and saved her from many distractions of attention. It may indeed fairly be surmised that but for her deafness she could never have found time to achieve the amazing quantity of work that she did, while the courageous, cheerful, and unobtrusive spirit in which she bore her infirmity remains an example and an encouragement to all her fellow-sufferers. (C. BL.)

MARTINI, Giovanni Battista (1706–1784), the most learned musician of the 18th century, was born at Bologna on April 25, 1706. His father, Antonio Maria Martini, a violinist, taught him very early the elements of music, and to play the violin; at a later period he learned singing and harpsichord playing from Padre Pradieri, and counterpoint from Antonio Riccieri. Having received his education in classics from the fathers of the oratory of San Filippo Neri, he afterwards entered upon a noviciate at the Franciscan monastery at Lago, at the close of which he was received into that order on September

11, 1722. Continuing his studies in the theory and practice of music with great zeal, he in 1725, though only nineteen years of age, received the appointment of chapel-master in the Franciscan church at Bologna, where his compositions soon attracted much attention. At the invitation of amateurs and professional friends he now opened a school of musical composition at which in the course of his long life several celebrated musicians were trained, including Paolucci, Sabbatini, Ruttini, Zanotti, Sarti, Ottani, and Stanislas Mattei; as a teacher he consistently declared his preference for the traditions of the old Roman school of musical composition (see Music). Padre Martini was a zealous and indefatigable collector of musical literature, and is alleged to have been the possessor of the most extensive musical library ever formed. After a lingering illness he died at Bologna on August 4, 1784. His *Elogio* was published by Pietro della Valle at Bologna in the same year.

The greater number of Martini's sacred compositions remain unprinted. The Liceo of Bologna possesses the MSS. of two oratorios; and a requiem, with some other pieces of church music, are now in Vienna. *Litaniæ atque antiphonæ finales B. V. Mariæ* were published at Bologna in 1734, as also twelve *Sonate d'intavolatura*; six *Sonate per l'organo ed il cembalo* in 1747; and *Duetti da Camera* in 1763. Martini's most important works are his *Storia della Musica* (Bologna, 1757–81) and his *Saggio di Contrapunto* (Bologna, 1774–75). The former, of which the three published volumes relate wholly to ancient music, and thus represent a mere fragment of the author's vast plan, exhibits immense reading and industry, but it is written in a dry and unattractive style, and is overloaded with matter which cannot be regarded as historical. At the beginning and end of each chapter occur puzzle-canons, some of which are exceedingly difficult; Cherubini solved the whole of them. The *Saggio* is a very learned and valuable work, containing an important collection of examples from the best masters of the old Italian and Spanish schools, with excellent explanatory notes. It treats chiefly of the tonalities of the plain chant, and of counterpoints constructed upon them. Besides being the author of several controversial works, Martini drew up a *Dictionary of Ancient Musical Terms*, which appeared in the second volume of G. B. Doni's *Works*; he also published a treatise on *The Theory of Numbers as applied to Music.*

MARTINI, Simone (1283–1344), called also Simone di Martino, and more commonly, but not correctly, Simon Memmi,[1] was born in 1283. He followed the manner of painting proper to his native Siena, as improved by Duccio, which is essentially different from the style of Giotto and his school, and the idea that Simone was himself a pupil of Giotto is therefore wide of the mark. The Sienese style is less natural, dignified, and reserved than the Florentine; it has less unity of impression, has more tendency to pietism, and is marked by exaggerations which are partly related to the obsolescent Byzantine manner, and partly seem to forebode certain peculiarities of the fully developed art which we find prevalent in Michelangelo. Simone, in especial, tended to an excessive and rather affected tenderness in his female figures; he was more successful in single figures and in portraits than in large compositions of incident. He finished with scrupulous minuteness, and was elaborate in decorations of patterning, gilding, &c.

The first known fresco of Simone is the vast one which he executed in the hall of the Palazzo Pubblico in Siena,—the Madonna Enthroned, with the Infant, and a number of angels and saints; its date is 1315, at which early period of his life he was already an artist of repute throughout Italy. In S. Lorenzo Maggiore of Naples he painted a life-sized picture of King Robert crowned by his brother, Lewis, bishop of Toulouse; this also is extant, but much damaged. In 1320 he painted for the high altar of the church of St Catharine in Pisa the Virgin and Child between six saints; above are archangels, apostles, and other figures. The compartmented portions of this work are now dispersed, some of them being in the academy of Siena. Towards 1321 he executed for the church of St Dominic in Orvieto a picture of the bishop of Savona kneeling before the Madonna attended by saints, now in the Fabricceria of the cathedral. Certain frescos in Assisi in the chapel of St Martin, representing the life of that saint, ascribed by Vasari to Puccio Capanna, are now, upon strong internal evidence, assigned to Simone. He painted also, in the south transept of the lower church of the same edifice, figures of the Virgin and eight saints. In 1328 he produced for the Sala del Consilio in Siena a work of a very different character—a striking equestrian portrait of the victurious general Guidoriccio Fogliani de' Ricci.

Simone had married in 1324 Giovanna, the daughter of Memmo (Guglielmo) di Filippuccio. Her brother, named Lippo Memmi, was also a painter, and was frequently associated with Simone in his work; and this is the only reason why Simone has come down to us with the family-name Memmi. They painted together in 1333 the Annunciation which is now in the Uffizi gallery. Simone kept a bottega (or shop), undertaking any ornamental work commissioned of him, and his gains were large. In 1339 he settled at the papal court in Avignon, where he made the acquaintance of Petrarch and Laura; and he painted for the poet a portrait of his lady, which has not come down to us; it gave occasion for two of Petrarch's sonnets, in which Simone is highly eulogized. He also illuminated for the poet a copy of the Comment of Servius upon Virgil, now preserved in the Ambrosian library of Milan. He was largely employed in the decorations of the papal buildings in Avignon, and several of his works still remain —in the cathedral, in the hall of the consistory, and, in the two chapels of the palace, the stories of the Baptist, and of Stephen and other saints. One of his latest productions (1342) is the picture of Christ Found by his Parents in the Temple, now in the Liverpool Gallery. Simone died in Avignon in July 1344.

From this account of Simone's principal works it will be perceived that those with which his name and fame are most generally identified are no longer regarded as his. These are the compositions, in the Campo Santo of Pisa, from the legend of S. Ranieri, and the Assumption of the Virgin; and the great frescos in the Cappellone degli Spagnuoli, in S. Maria Novella, Florence, representing the Triumph of Religion through the work of the Dominican order, &c. Some of the works in question can be proved to have been done many years after Simone's death, and the others belong to a different school and style of art.

MARTINIQUE, one of the West India islands, belonging to the chain of the Lesser Antilles, and constituting a French colony, lies 33 miles south of Dominica and 22 north of Saint Lucia, between 14° 23′ and 14° 52′ N. lat. and 63° 6′ and 63° 31′ W. long. The greatest length is 43 miles, the mean width 19; and the surface comprises 244,090 acres, or 380 square miles. A cluster of volcanic mountains in the north, a similar group in the south, and a line of lower heights between them, form the backbone of the island, which culminates in the north-west in Mont Pelée (4430 feet), and has altogether a much more irregular and strongly marked relief than it presents to the eye,—the deep ravines and precipitous escarpments with which it abounds being reduced in appearance to gentle undulations by the drapery of the forests. Of the numerous streams which traverse the few miles of country between the watershed and the sea, about seventy or eighty

[1] The ordinary account of this celebrated early Sienese painter is that given by Vasari, and since repeated in a variety of forms. Modern research shows that it is far from correct, the incidents being erroneous, and the paintings attributed to Simone in various principal instances not his. We follow the authority of Messrs Crowe and Cavalcaselle.

are of considerable size, and in the rainy season become deep and too often destructive torrents. The east coast of the island, exposed to the full sweep of the Atlantic, is a succession of inlets, headlands, islands, and rocks; the south coast is much more regular, but bold and steep; and the west alone presents, in the bay of Fort de France, a stretch of mangrove swamp. Of the total area, about 83,990 acres are under cultivation, 83,843 occupied by forest and savanna, and 68,837 by fallow. On an average, according to the returns for 1874–78 inclusive, 47,440 acres are devoted to the sugar crop, 1290 to coffee, 640 to cotton, and 1660 to cocoa. The mean annual temperature is 81° in the coast region,—the monthly mean for June being 83°, and that of January 77°. Of the annual rainfall of 87 inches, August has the heaviest share (11·3 inches), though the rainy season extends from June to October; March, the lowest, has 3·7. Martinique enjoys a remarkable immunity from hurricanes; half a century may pass without serious disaster from such a visitation. In 1878 there were 162,861 inhabitants (77,782 males, 85,079 females) in the island, which is thus nearly as densely peopled as Belgium. Since 1848 the increase amounts to about 42,800. Of the twenty-five communes, fourteen have more than 5000 inhabitants; the largest are Saint Pierre (23,909), Fort de France (15,414), Lamentin (13,409), and François (10,297). The great mass of the population consists of Creole negroes and half-castes of various grades, ranging from the "Saccatra," who has hardly retained any trace of Caucasian blood, to the so-called "Sangmêlé," with his mere suspicion of negro commixture. Marriage is frequently ignored, and of the births no less than 66 per cent. are illegitimate.

Fort de France, the chief town, a place of about 11,000 inhabitants, stands on a bay on the west coast. Since the earthquake of 1839 nearly all the houses are of wood, and have only one story; the streets are laid out with great regularity. An abundant supply of water was introduced in 1856. St Pierre, the commercial centre of the island, with about 20,000 inhabitants, lies farther north on the same coast. It consists of a lower and an upper town,—the one close and unhealthy, and the other for the most part well-ventilated and pleasant.

Martinique, also called Madiana or Mantinino, was discovered by Columbus 15th June 1502. It was at that time inhabited by Caribs (Galibis) who had expelled or incorporated an older stock. In 1635 a Norman captain, D'Enambuc, from St Christopher's, took possession of the island, and in 1637 his nephew Duparquet became captain-general of the colony, now numbering seven hundred men. In 1654 welcome was given to three hundred Jews expelled from Brazil, and by 1658 there were at least five thousand people exclusive of the Caribs, who were soon after exterminated. Purchased by the French Government from Duparquêt's children for 120,000 livres, Martinique was assigned to the West India Company, but in 1674 it became part of the royal domain. The *habitants* (French landholders) at first devoted themselves to the cultivation of cotton and tobacco; but in 1650 sugar plantations were commenced, and in 1726 the coffee plant was introduced by Desclieux, who, when water ran short during his voyage to the island, shared his scanty allowance with his seedlings. Slave labour having been introduced, there were 72,000 blacks in the island by 1736. Martinique has several times been occupied by the English. Captured by Rodney in 1762, it was next year restored to the French; but after the conquest by Sir John Jervis and Sir Charles Grey in 1794 it was retained for eight years; and, seized again in 1809, it was not surrendered till 1814.

See Renouard, *Stat. de la Martinique*, 1822; Sidney Daney, *Hist. de la Martinique*, 1846; E. Rufz, *Études hist. et stat. sur la population de la Martinique*; Pardon, *La Martinique*, 1877; H. Rey, *Étude sur la col. de la Martinique*, 1881.

MARTINSBURG, a town of the United States, the capital of Berkeley county, West Virginia, lies on a plateau above the Tuscarora Creek, in the Shenandoah valley, 80 miles west of Washington. A station on the Baltimore and Ohio Railroad, and a terminus of the Cumberland Valley Railway, Martinsburg is the seat of extensive machine-shops belonging to the former company, which were sacked by the Confederates in 1861. The population, 4868 in 1870, was 6335 in 1880.

MARTIUS, Carl Friedrich Philipp von (1794–1868), a well-known German botanist and traveller in Brazil. He studied in the university of Erlangen, and on graduating M.D. in 1814 published as his thesis a critical catalogue of plants in the botanic garden of the university. He afterwards devoted himself to botanical study, and in 1817 he and Spix were sent to Brazil by the king of Bavaria. They travelled from Rio Janeiro through several of the southern and eastern provinces of Brazil, and ascended the river Amazon to Tabatinga, as well as some of its larger affluents. In 1820 they returned to Europe with rich collections of plants and animals, as also with stores of information on the geography, ethnology, and products of Brazil. In 1820 he was appointed conservator of the botanic garden at Munich, and in 1826 professor of botany in the university there, and held both offices till 1854, when he resigned them.

While a student Martius had published papers in various scientific periodicals, and he continued to do so during his whole life. After his return from Brazil he devoted his chief attention to the flora of that country, and in addition to numerous short papers he published the *Nova Genera et Species Plantarum Brasiliensium* (1823–32, 3 vols.) and *Icones selectæ Plantarum Cryptogamicarum Brasiliensium* (1827), both works being finely illustrated. An account of his travels in Brazil appeared in 3 vols. 4to, 1823–31, with an atlas of plates, and is regarded as one of the most valuable works of travel of the present century. Probably the work by which he is best known is his *Historia Palmarum* (1823–50) in 3 large folio volumes, of which one describes the palms discovered by himself in Brazil. In 1840 he began the *Flora Brasiliensis* with the assistance of the most distinguished European botanists, who undertook monographs of the various orders. Latterly Dr Eichler was associated with him in the editorship of this work, which is still going on, though over eighty parts have appeared. He also edited several works on the zoological collections made in Brazil by Spix, after the death of the latter in 1826. On the outbreak of potato disease in Europe he investigated the state of the diseased plants, and in 1842 published his observations. He also published independent works and short papers on the aborigines of Brazil, on their civil and social condition, on their past and probable future, on their diseases and medicines, and on the languages of the various tribes, especially the Tupi.

MARTOS, a town of Spain, in the province of Jaen, is situated on the slope of a steep hill, which is surmounted by a ruined castle, 16 miles west-south-west of Jaen. The streets are steep, narrow, crooked, and ill-paved; the public buildings are of the usual order, and present no feature calling for special remark. The surrounding district is specially productive of oil, and in the neighbourhood of the town are two sulphurous springs much resorted to in cases of cutaneous disease. Population in 1877, 14,654.

Martos perhaps stands on or near the site of the *Tucci* of Ptolemy. By Ferdinand III. it was taken from the Moors in 1225, and given to the knights of Calatrava; it was there that the brothers Carvajal, commanders of the order, were in 1410 executed by command of Ferdinand IV. after he had been "summoned" by them to a meeting at the Divine judgment seat. O'Donnell here gained a victory over the royalist troops in 1854.

MARTYN, Henry (1781–1812), a celebrated missionary, was born on February 18, 1781, at Truro, Cornwall. He came of a mining family, and his father John Martyn was a "captain" or mine-agent at Gwennap. He received his education at the grammar school of his native town under the famous Dr Cardew, entered St John's College, Cambridge, in the autumn of 1797, and in 1801, a month before he was twenty years old, was declared senior wrangler, obtaining soon after the first Smith's prize. In the following year he was chosen a fellow of his college. In the autumn of 1801 he was introduced to Charles Simeon, whose ardent disciple he soon became. It was his intention to devote himself to the bar, but in the October term of 1802 he chanced to hear Simeon speaking of the vast amount of good done in India by a single missionary, William Carey; some time

afterwards he read the life of the devoted David Brainerd, the enthusiastic apostle of the Indians of North America, and, "filled with a holy emulation," resolved to devote his energies to the work of a Christian missionary. On October 22, 1803, he was ordained deacon at Ely, and afterwards priest, and served as Simeon's curate at the church of Holy Trinity, taking charge of the neighbouring parish of Lolworth. Still full of the thought of working in heathen lands, he designed to volunteer for the Church Missionary Society, but a sudden disaster in Cornwall deprived him and his unmarried sister of all the provision their father had made for them, and rendered it necessary that he should obtain a salary that would support her as well as himself. He accordingly applied for, and obtained, a chaplaincy under the East India Company. He left for India on July 5, 1805.

For some months he was chiefly located at Aldeen, near Serampore; in October 1806 he proceeded to Dinapore, where he laboured for a time amongst the Europeans, and soon found himself able to conduct divine worship among the natives in their own vernacular language, and to establish schools for their instruction. At the end of April 1809 he was ordered up to Cawnpore, where he made his first attempt to preach to the heathen in his own compound, and had to endure frequent interruptions "amidst groans, hissings, curses, blasphemies, and threatenings"; nevertheless he pursued his work among the hundreds who crowded round him, consoling himself that, if he should never see a native convert, God "might design by his patience and continuance in the work to encourage other missionaries." Meanwhile the great business of his life was being diligently carried on. Day after day he occupied himself with learning new languages, and had already, during his residence at Dinapore, been engaged in revising the sheets of his Hindustani version of the New Testament. He now translated the whole of the New Testament into Hindi also, and into Persian twice over. He translated the Psalms into Persian, the Gospels into Judæo-Persic, and the prayer book into Hindustani, in spite of the constant interruptions caused by excessive weakness of body, and "the pride, pedantry, and fury of his chief moonshee Sabat." Ordered by the doctors to take a sea voyage for his health, he got leave to go to Persia and correct his Persian New Testament, whence he made up his mind to go on to Arabia, and there compose an Arabic version. Accordingly, on October 1, 1810, having seen his work at Cawnpore crowned, on the previous day, by the opening of a church, he left for Calcutta, whence he departed on January 7, 1811, for Bombay, which he reached on his thirtieth birthday. From Bombay he set out for Bushire, bearing letters from Malcolm to men of position there, as also at Shiraz and Ispahan. After a killing journey from the coast he reached Shiraz, and was soon plunged into discussion with the disputants of all classes, "Sufi, Mohammedan, Jew, and Jewish-Mohammedan, even Armenian, all anxious to test their powers of argument with the first English priest who had visited them." Having made an unsuccessful journey to Tebriz to present the shah with his translation of the New Testament, he was seized with a fever, which so thoroughly prostrated his energies that, after a temporary recovery, he found it necessary to seek a change of climate. On September 12, 1812, he started with two Armenian servants, crossed the Araxes, rode from Tebriz to Erivan, from Erivan to Kars, from Kars to Erzeroum, from Erzeroum to Chiflik, urged on from place to place by his cruel Tartar guide, and, though the plague was raging at Tokat, he was compelled to stop there from utter prostration caused by fever. On the 6th of October he died, either from the plague or from the weakness of the disorders which harassed him from day to day

By his valuable labours as a translator Martyn had placed portions of the Scriptures within the reach of all who could read over one-fourth of the habitable globe, and during his brief life he earned for himself a foremost place among modern missionaries. Macaulay's lines, written in 1818, testify to the impression made by his enthusiastic career of self-devotion.

See Sargent, *Memoir of the Rev. Henry Martyn, B.D.*, 1819; Wilberforce, *Journals and Letters of the Rev. Henry Martyn*, 1837; Kaye, *Christianity in India*, 1859; Yonge, *Pioneers and Founders*, 1874; and *The Church Quarterly* for October 1881.

MARTYROLOGY, a catalogue or list of martyrs, arranged according to the succession of their anniversaries, and sometimes including an account of their lives and sufferings. The corresponding word in the Greek Church is *Menologion* or *Analogion*; from the *Menologia* the *Synaxaria* are compiled. The custom of paying honour to the memory of those who had "witnessed the good confession" in perilous times established itself very early in the Christian church, and one particular manner of commemoration was formally recognized by at least one ecclesiastical synod before the end of the 4th century; in the 47th canon of the third synod of Carthage (397 A.D.) it is decreed "liceat legi Passiones Martyrum quum anniversarii eorum dies celebrantur." Apart from the still extant *Depositio Martyrum* contained in the work of the chronographer of 354, edited in 1850 by Mommsen, the oldest "martyrologies" of which anything is known are the *ἀρχαίων μαρτυρίων συναγωγή*, or collection of records of past persecutions, to which Eusebius more than once alludes as having been made by himself, and the treatise *On the Martyrs of Palestine*, by the same author, the full text of which has been preserved in an ancient Syriac version edited by Cureton. Next to the general martyrology of Eusebius, in chronological order, it has been usual to place the calendar of saints' days referred to in a letter, attributed to Jerome, which purports to be written in answer to bishops Chromatius and Heliodorus, who had asked him to search the archives of Eusebius with the view of enabling them to observe the saints' days with more regularity. This epistle is now admitted to be spurious; ultimately, however, a so-called *Martyrologium Hieronymianum* came into existence, but it is not so much a single martyrology as a rude patchwork derived from many ancient church calendars. In its present form it is a meagre list of names and places, but may be said to lie at the foundation of all subsequent Western calendars. Almost contemporary with its last recension is what is known as the *Parvum Martyrologium Romanum*, found by Ado of Vienne about 850; in it many of the dates are changed, and for the first time days are assigned to the chief characters of Scripture. To nearly the same date must be assigned the independent compilation of Bede, which has reached us, however, only as enlarged by subsequent editors. The 9th century was very fertile in martyrologies, among which may be mentioned that of Florus, subdeacon of Lyons (*c.* 830), who was the first editor of Bede, that of Hrabanus Maurus, an attempted further improvement on Bede and Florus, that of Ado, an enlargement of Florus, but based on the *Parvum Martyrologium Romanum*, that of Usuard of Paris, the epitomizer of Ado, and that of Notker of St Gall, based on Ado and Hrabanus. The *Martyrologium Romanum* was published by Baronius at the command of Pope Gregory XIII. in 1586; the enlarged edition by Rosweyd appeared at Antwerp in 1613. The Cistercian *Martyrology* appeared at Rome in 1733 and 1748. The best-known Greek *Menologion* is that prepared in the 9th century by command of the emperor Basilius Macedo; it was edited in 1727 by Cardinal Hannibal Urbini. An ancient Syriac martyrology, entitled "the names of our lords the martyrs and victors, with their days on which they won crowns," written in 412, has been edited, with an English translation, by Professor W. Wright, in the *Journal of Sacred*

*Literature* (1866). See *Catal. Syr. MSS. Br. Mus.*, ii. 632.

MARULLUS, Michael Tarchaniota (*ob.* 1500), one of the most brilliant scholars of the golden age of Florentine learning, was born at Constantinople, and at an early age, on the fall of his native city, was brought to Ancona in Italy, where he became the friend and pupil of Pontanus, with whom his name is associated by Ariosto (*Orl. Fur.*, xxxvii. 8). He was a soldier and a poet, and in the latter capacity published epigrams and *hymni naturales*.[1] Marullus took no part in the work of translation, then so favourite an exercise of scholars, but he was understood to be planning some great work when he perished, 10th April 1500, in the river Cecina near Volterra. Of other incidents in his life his feud with Politian and his marriage to the beautiful and learned Alexandra Scala, whom he praises in his poems, may be noticed. The name of Marullus is now perhaps most familiar from the brilliant emendations on Lucretius which he left unpublished, and which were used for the Juntine edition. See especially Munro's *Lucretius*, 2d ed., p. 6 *sq.*

MARUM (in Dutch Marwm), Martin Van (1750–1837), a distinguished Dutch man of science, born at Delft. Though his fame rests chiefly on his electrical researches, he took a prominent position in many departments of natural science. He graduated at Groningen in medicine and philosophy, and his numerous papers take up subjects connected with botany, chemistry, hygiene, natural history, and technology, as well as with his more special department, natural philosophy. In early life his father, who was a skilled mathematician, gave him a thorough training in the one really indispensable science. After his doctorate he for some time attached himself to the celebrated botanist Camper. He then commenced medical practice in Haarlem, but seems to have been too busy with original work to pay proper attention to his numerous patients. He devoted himself mainly to lecturing on physical subjects; and, after a brief interval, his extensive knowledge and methodical habits led to his being made secretary of the scientific society of his adopted city. For this post he was specially fitted; and, under his active guidance, the society was advanced to the position of one of the most noted in Europe. He soon became professor of physics, and was entrusted with the care of the celebrated Teyler collection (now the Musée Teyler). He caused to be constructed for this, by Cuthbertson, the gigantic electrical machine which, for a long period, was the most powerful in the world. He also effected great improvements in air-pumps and other pneumatic machines. Though his name is not associated with any discovery of the very first order, the number and variety of his researches (especially in connection with electricity) are remarkable. So also is the practical mode in which he regarded his results, always when at all possible from the technological point of view. The work by which he is best known is his *Treatise on Electricity* (Groningen, 1776), in which all that had then been discovered in that science was carefully methodized. Van Marum was a man of quiet but active disposition, and of simple habits and tastes, which probably conduced in no small measure to the extreme length and usefulness of his life.

MARUTSE-MABUNDA, a kingdom in South Africa, stretching from 18° to 14° 25′ S. lat. and from about 22° to 28° 25′ E. long., with an area estimated at 123,590 square miles. It all belongs to the basin of the Zambesi, and by far the greater proportion lies to the north of that river, which forms its south-eastern boundary from the mouth of the Linyanti to the mouth of the Kafue, a distance of about 350 miles. The kingdom thus includes the main part of the territory formerly subject to the Makololo empire, which broke up on the death of Sekeletu in 1864. Of country and people Dr Holub gives a very favourable report. Abundance of water, a fertile soil, and a genial climate render easy the work both of husbandry and cattle-breeding. The chief crop is Kaffre corn, red and white; the hemp-like kleen-korn or *rosa*, maize, watermelons, sugar-cane, ground-nuts, two kinds of beans, and *manza* are also cultivated. "September and October are the usual months for sowing; but gourds, leguminous plants, and tobacco are sown any time up to December, the growth of the two latter crops being so rapid that they often ripen by January, whilst Kaffre corn and maize are ready by February." Upwards of fifty kinds of wild fruit are used by the people as food. Salt has to be imported, and is consequently within the reach only of the wealthier classes. Besides the two great tribes which give their name to the kingdom, there are a large number of vassal tribes of numerical importance—Masupias, Matongas, Makalakas—all considered in the light of slaves by the rulers. The prevailing language is the Sesuto of the nearly extirpated Makololos. See Holub, *Seven Years in South Africa*, 1881.

MARVELL, Andrew (1621–1678), was born on March 31, 1621, at the parsonage of Winestead in Holderness. He was educated at Hull grammar school by his father, who had obtained high position in that town, until his admission to Trinity College, Cambridge, on December 14, 1633. There he became ensnared by the Jesuits, who at that time were keen to secure youths of promise at the universities, and by them, probably in the beginning of 1638, was taken to London; but he was recaptured by his father, and again received into Trinity on April 13 of the same year. He appears to have contributed to the *Musa Cantabrigiensis* in 1637; and beyond this nothing is known or even conjectured as to his college career. In 1640 his father was drowned under remarkable circumstances, an event which appears to have entirely unsettled him, for by an entry in the College Conclusion book, dated September 24, 1641, we find that he was adjudged by the seniority to have forfeited the benefits of the college. He used his liberty during the next four years to travel through the Continent, remaining abroad until 1646. It has been assumed that during this journey Marvell became acquainted with Milton, but a comparison of dates shows that this is an error. His first employment was in 1650, as tutor to Lord Fairfax's daughter. During his stay at Nunappleton were written the *Poems of the Country* and some of the *Poems of Imagination and Love*. In 1652 he was in communication with Milton, to whom he had probably been introduced by Fairfax, and was by him sent on February 21 to President Bradshaw with a letter urging his appointment as assistant Latin secretary to himself. The post was, however, otherwise filled up, and he was provided instead with another tutorship, that of Cromwell's nephew, Mr Dutton. This has been wrongly stated by several writers as not occurring until six years later. In 1657 the secretaryship again fell vacant, and was then conferred upon him, but he held office for a year only, and no record of his work appears in the calendars of state papers. Marvell accepted the Commonwealth as a practical fact, and the rule of Cromwell as the only guarantee for government at once tolerant and strong. But he never lost his belief in the monarchical theory. His line "'Tis godlike good to save a falling king" is well known; and throughout his most vehement invective against corruption there is a great tenderness and desire to spare the king

[1] Two books of epigrams appeared first without date; an enlarged edition, with two additional books, published in 1497, contains also the so-called hymns

The assistant secretaryship opened the way to public life, and in 1658 Marvell was elected member for Kingston-upon-Hull in Richard Cromwell's parliament. From 1663 to 1665 he acted as secretary to Lord Carlisle's embassy to Muscovy, Sweden, and Denmark; and this is the only official post he ever filled during the reign of Charles. With the exception of this and of shorter unexplained intervals of travel, Marvell was constant in his parliamentary attendance to the day of his death. He seldom spoke in the House, some five or six times in all, but his parliamentary influence is amply established by other evidence; and his correspondence with his constituents, from 1660 to 1678, forms a source of information all the more valuable because by a resolution passed at the Restoration the publication of the proceedings of the House without leave was forbidden. He made it a point of duty to write at each post—that is, every two or three days—both on local interests and on all matters of public interest. The discreet reserve of these letters, natural at a time when the post-office was a favourite source of information to the Government, contrasts curiously with the freedom of the few private letters which state opinions as well as facts. Marvell's constituents, in their turn, were not unmindful of their member. He makes frequent references to their presents, usually of Hull ale and of salmon, and he regularly drew from them the wages of a member, six and eightpence a day during session.

During these years Marvell wrote a good deal of verse, chiefly satire, often very coarse, but always vigorous and full of an honest hatred at corruption. He chose verse merely as being the usual vehicle of satire, and cared little about form. "He plucked a cudgell from the nearest hedgerow, careless if it became fuel after it had served his turn." It was very different with his prose satires. His peculiar talent was first displayed in the mock *King's Speech*, issued in 1675. This is written in a vein of genial banter, perhaps the greatest tribute to the influence which the bonhomie of Charles exercised even over such men as Marvell. But his tone soon changed, and *The Growth of Popery and Arbitrary Power*, published in the year of his death, is a grave indictment of the conduct of ministers of the crown, and, by implication, of Charles himself, since the Restoration. So shrewdly did this strike the conscience of the king that a proclamation, of which Marvell takes laughing notice, offered a large reward for the discovery of the author.

As a political pamphleteer Marvell holds a high place; as a satirist he stands still higher. Tolerance in religion was his creed, and this creed had been lately attacked by a clergyman seeking promotion, Dr Parker, afterwards bishop of Oxford, who asserted in their most extravagant form the claims of the civil magistrate over the consciences of subjects in matters of external religion. Marvell's reply, *The Rehearsal Transprosed*, is a masterpiece of prolonged banter. It contains passages of lofty indignation, hearty laughter, coarse vituperation; but the prevailing tone is that of grave and ironical banter. The effect, as witnessed to by Anthony Wood, Burnet, and other contemporary writers, was to set the whole public "from the king to the tradesman" in a laugh against Parker. This stung him to an ill-tempered rejoinder, affording Marvell a second opportunity, of which he availed himself so well that no more was heard from his opponent; and Swift was shortly afterwards able to say that people remembered Parker's book only by Marvell's answer. Marvell's second controversial work, *Mr Smirke, or the Divine in Mode*, was written in the same strain and under similar circumstances, and obtained a success fully equal to that of the *Rehearsal Transprosed*. It was a defence of Croft, bishop of Hereford, against a violent attack by Dr Turner, the High Church master of St John's, Cambridge. Prefixed to it was a "short historical essay concerning general councils," intended to show the folly of religious impositions. Several other writings, often ascribed to him, more especially the *Parliamenti Angliæ Declaratio*, *A Sensible Question and an Usefull Answer*, and the *Flagellum Parliamentarium*, were certainly not his.

As a humorist, then, and as a great "parliament man," no name is of more interest to a student of the reign of Charles II. than that of Marvell. But other qualities entitle him to still higher respect. To a personal charm so great, to wit so brilliant, to learning so extensive, and to sympathies so wide that he was at the same time dear to John Milton and courted by Charles II., he joined the rarest quality of that evil time, a robust and intrepid rectitude. In the very heyday of political infamy, at a time when he says passionately "we are all venal cowards except some few," and when opposition to the court was likely to be resented by personal violence of the brutalest kind, he, a needy man, obliged to accept wages from his constituents, tempted in winning phrases from royal lips by his old schoolfellow Danby, and with nothing to gain from the court by purity, kept his political virtue unspotted and unsuspected. The meaning of this fact can barely be felt by any one who has not read with minute care the annals of that time. When the grossest forms of self-indulgence were the ordinary habits of town life, Marvell was a temperate man, in spite of Aubrey's witness that he "kept bottles of wine at his lodgings and would drink liberally by himself to refresh his spirits and exalt his muse." Lastly, in the worst times of parliamentary violence, he stood forward throughout his career as the champion of moderate and tolerant measures. His person corresponded singularly with his mind, so far as can be judged from the portrait by Hannemann and from the few words of John Aubrey—"He was of a middling stature, pretty strong set, roundish faced, cherry cheeked, hazel eyed, brown haired. In his conversation he was modest and of very few words."

He died suddenly in 1678 on his return from Hull to take his seat in August. That he was poisoned, and at the instigation of the court, has been roundly asserted, naturally enough, though without the slightest foundation. The matter has been finally set at rest by a very interesting letter by Dr Samuel Gee in the *Athenæum* for March 7, 1874.

The following works may be consulted on Marvell:—*Life and Works*—(1) by Thomas Cooke, 2 vols., 1726 (there is a reprint by Thomas Davies in 1772); (2) by Captain Thomson, 3 vols. 4to, 1776; (3) by John Dove, 1832; (4) by Edwin Paxton Hood, 1853; and essays by Hartley Coleridge in *Lives of the Northern Worthies*, Henry Rogers in his collected *Essays*, and an anonymous author in the *Cornhill Magazine* for July 1869, and in the *Saturday Review* for April 26, 1873. All these authorities are mentioned, collated, and corrected in the very important and laborious work of Mr Grosart, whose book, in spite of its excessive mannerism and one or two curious inaccuracies, is indispensable to the student of Marvell's correspondence and career. (O. A.)

MARWAR. See JODHPUR.

MARY[1] (Μαρία, Μαριάμ), the mother of Jesus, at the time when the gospel history begins, had her home in

[1] The name (Heb. מִרְיָם), that of the sister of Moses and Aaron, is of uncertain etymology; many interpretations have been suggested, including "stella maris," which, though it has attained considerable currency through Jerome (the *Onomasticon*), may be at once dismissed. It seems to have been very common among the Jews in New Testament times; besides the subject of the present notice there are mentioned (1) "Mary (the wife) of Clopas," who was perhaps the mother of James "the little" (ὁ μικρός) and of Joses (see vol. xiii. pp. 552, 553); (2) Mary Magdalene, *i.e.*, of Magdala; (3) Mary of Bethany, sister of Martha and Lazarus; (4) Mary the mother of Mark (see MARK); and (5) Mary, an otherwise unknown benefactress of the apostle Paul (Rom. xvi. 6).

Galilee, at the village of Nazareth. Of her parentage nothing is recorded in any extant historical document of the 1st century, for the genealogy in Luke iii. (*cf.* i. 27) is manifestly that of Joseph. In early life she became the wife of JOSEPH (*q.v.*) and also the mother of our Lord (see JESUS[1]); that she afterwards had other children is a natural inference from Matt. i. 25, which the evangelists, who frequently allude to "the brethren of the Lord," are at no pains to obviate. The few incidents mentioned in Scripture regarding her show that she followed our Lord to the very close of His earthly career with unfailing motherliness, but the "Magnificat" assigned to her in Luke i. is the only passage which would distinctly imply on her part a high prophetic appreciation of His divine mission. She was present at the crucifixion, where she was commended by Jesus to the care of the apostle John, (John xix. 26, 27), Joseph having apparently died before this time. (It would be idle to inquire why "the brethren of the Lord," who, whatever their relationship to Mary, must at least have been nearer than John, were ignored in this arrangement.) Mary is mentioned in Acts i. 14 as having been among those who continued in prayer along with the apostles at Jerusalem during the interval between the ascension and pentecost. There is no allusion in the New Testament to the time or place of her death.

The subsequent growth of ecclesiastical tradition and belief regarding Mary will be traced most conveniently under the separate heads of (1) her perpetual virginity, (2) her absolute sinlessness, (3) her peculiar relation to the Godhead, which specially fits her for successful intercession on behalf of mankind.

*Her Perpetual Virginity.*—This doctrine, as has already been pointed out, was, to say the least, of no importance in the eyes of the evangelists, and so far as extant writings go there is no evidence of its having been anywhere taught within the pale of the catholic church of the first three centuries. On the contrary, to Tertullian the fact of Mary's marriage after the birth of Christ is a useful argument for the reality of the Incarnation against Gnostic notions, and Origen relies upon the references to the Lord's brethren as disproving the Docetism with which he had to contend. The ἀειπαρθενία, though very ancient, is in reality a doctrine of non-catholic origin, and first occurs in a work proscribed by the earliest papal *Index Librorum Prohibitorum* (attributed to Gelasius) as heretical,—the so-called *Protevangelium Jacobi*, written, it is generally admitted, within the 2d century. According to this very early source, which seems to have formed the basis of the later *Liber de Infantia Mariæ et Christi Salvatoris* and *Evangelium de Nativitate Mariæ*, the name of Mary's father was Joachim (in the *Liber de Infantia* a shepherd of the tribe of Judah, living in Jerusalem); he had long been married to Anna her mother, whose continued childlessness had become a cause of much humiliation and sorrow to them both. The birth of a daughter was at last angelically predicted to each parent separately. From her third to her twelfth year "Mary was in the temple as if she were a dove that dwelt there, and she received food from the hand of an angel." When she became of nubile age a guardian was sought for her by the priests among the widowers of Israel "lest she should defile the sanctuary of the Lord"; and Joseph, an elderly man with a family, was indicated for this charge by a miraculous token. Some time afterwards the annunciation took place; when the Virgin's pregnancy was discovered, Joseph and she were brought before the high priest, and, though asserting their innocence in all sincerity, were acquitted only after they had been tried with "the water of the ordeal of the Lord" (Numb. v. 11). Numerous details regarding the birth at Bethlehem are then given. The perpetual physical virginity of Mary, naively insisted upon in this apocryphon, is alluded to only with a half belief and a "some say" by Clement of Alexandria (*Strom.*, vii. 16), but became of much importance to the leaders of the church in the 4th century, as for example to Ambrose, who sees in Ezek. xliv. 1–3 a prophetic indication of so great a mystery.[2] Those who continued to believe that Mary, after the miraculous birth of Jesus, had become the mother of other children by Joseph came accordingly to be spoken of as her enemies,—Antidicomarianitæ (Epiphanius) or Antidicomaritæ (Augustine),—and the first-mentioned author devotes a whole chapter (chap. 78) of his great work upon heresies to their confutation. For holding the same view Bonosus of Sardica was condemned by the synod of Capua in 391. To Jerome the perpetual virginity not only of Mary but even of Joseph appeared of so much consequence that while a young man he wrote (387) the long and vehement tract *Against Helvidius*, in which he was the first to broach the theory (which has since gained wide currency) that the brethren of our Lord were children neither of Mary by her husband, nor of Joseph by a former marriage, but of another Mary, sister to the Virgin and wife of Clopas or Alphæus. At last the epithet of ἀεὶ παρθένος was authoritatively applied to the Virgin by the council of Chalcedon in 451, and the doctrine implied has ever since been an undisputed point of orthodoxy both in the Eastern and in the Western church, some even seeking to hold the Anglican Church committed to it on account of the general declaration (in the *Homilies*) of concurrence in the decisions of the first four general councils.

*Her Absolute Sinlessness.*—While much of the apocryphal literature of the early sects in which she is repeatedly spoken of as "undefiled before God" would seem to encourage some such doctrine as this, many passages from the acknowledged fathers of the church could be cited to show that it was originally quite unknown to catholicism. Even Augustine repeatedly asserts that she was born in original sin (*De Gen. ad lit.*, x. 18); and the *locus classicus* regarding her possible immunity from actual transgression, on which the subsequent doctrine of Lombardus and his commentators was based, is simply an extremely guarded passage (*De Nat. et Grat.*, chap. 36) in which, while contradicting the assertion of Pelagius that many had lived free from sin, he wishes exception to be made in favour of "the holy Virgin Mary, of whom out of honour to the Lord I wish no question to be made where sins are treated of,—for how do we know what mode of grace wholly to conquer sin may have been bestowed upon her who was found meet to conceive and bear Him of whom it is certain that He had no sin." A writer so late as Anselm (*Cur Deus Homo*, ii. 16) declares that "the Virgin herself whence He (Christ) was assumed was conceived in iniquity, and in sin did her mother conceive her, and with original sin was she born, because she too sinned in Adam in whom all sinned," and the same view was expressed by Damian. The growth of the modern Roman doctrine of the immaculate conception from the time in the 12th century when the canons of Lyons sought to institute a festival in honour of her "holy conception," and were remonstrated with by Bernard, has been already sketched elsewhere (see IMMACULATE CONCEPTION).

[1] Vol. xiii. 656 *sq.*, where (p. 659) sufficient reference is made to the coarse view of this event taken by the later hostile Judaism (a view supposed by some to be alluded to even in John viii. 41). We learn from Origen that the story about the soldier Panthera (Πανθήρα) was already upheld by Celsus. The Ebionites and other heretical sects, as is well known, maintained the paternity of Joseph.

[2] *De Inst. Virg.*, "quæ est hæc porta nisi Maria! . . . per quam Christus intravit in hunc mundum, quando virginali fusus est partu et genitalia virginitatis claustra non solvit."

The epithets applied to her in the Greek Church are such as ἀμόλυντος, πάναγνος, ἁγία; but in the East generally no clear distinction is drawn between immunity from actual sin and original sinlessness.

*Her Peculiar Relation to the Godhead, which specially fits her for Successful Intercession on Behalf of Mankind.*—It seems probable that the epithet θεοτόκος ("Mother of God") was first applied to Mary by theologians of Alexandria towards the close of the 3d century; but it does not occur in any genuine extant writing of that period, unless we are to assign an early date to the apocryphal *Transitus Mariæ*, in which the word is of frequent occurrence. In the 4th century it is met with frequently, being used by Eusebius, Athanasius, Didymus, and Gregory of Nazianzus,—the latter declaring that the man who believes not Mary to have been θεοτόκος has no part in God (*Orat.*, ii. p. 738).[1] If, as is not unlikely, its use was first recommended by a desire to bring into prominence the divinity of the Incarnate Word, there can be no doubt that latterly the expression came to be valued as directly honourable to Mary herself and as corresponding to the greatly increased esteem in which she personally was held throughout the catholic world, so that, when Nestorius and others began to dispute its propriety in the following century, their temerity was resented, not as an attack upon the established orthodox doctrine of the Nicene creed, but as threatening a more vulnerable and more tender part of the popular faith. It is sufficient in illustration of the drift of theological opinion to refer to the first sermon of Proclus, preached on a certain festival of the Virgin (πανήγυρις παρθενική) at Constantinople about the year 430 or to that of Cyril of Alexandria delivered in the church of the Virgin Mary at the opening of the council of Ephesus in 431. In the former the orator speaks of "the holy Virgin and Mother of God" as "the spotless treasure-house of virginity, the spiritual paradise of the second Adam; the workshop in which the two natures were welded together . . . . the one bridge between God and men";[2] in the latter she is saluted as the "mother and virgin," "through whom (δι' ἧς) the Trinity is glorified and worshipped, the cross of the Saviour exalted and honoured, through whom heaven triumphs, the angels are made glad, devils driven forth, the tempter overcome, and the fallen creatures raised up even to heaven." The response which such language found in the popular heart was sufficiently shown by the shouts of joy with which the Ephesian mob heard of the deposition of Nestorius, escorting his judges with torches and incense to their homes, and celebrating the occasion by a general illumination. The causes which in the course of the preceding century had led to this exaltation of the Mother of God in the esteem of the catholic world are not far to seek. On the one hand the solution of the Arian controversy, however correct it may have been theoretically, undoubtedly had the practical effect of relegating the God-man redeemer for ordinary minds into a far away region of "remote and awful Godhead," so that the need for a mediator to deal with the very Mediator could not fail to be felt. On the other hand, it must be accepted as a fact abundantly proved by history that the religious instincts of mankind are very ready to pay worship, in grosser or more refined forms, to the idea of womanhood; at all events many of those who became professing Christians at the political fall of paganism entered the church with such instincts (derived from the nature-religions in which they had been brought up) very fully developed. Probably it ought to be added that the comparative colourlessness with which the character of Mary is presented not only in the canonical gospels but even in the most copious of the apocrypha left greater scope for the untrammelled exercise of devout imagination than was possible in the case of Christ, in the circumstances of whose humiliation and in whose recorded utterances there were many things which the religious consciousness found difficulty in understanding or in adapting itself to. At all events, from the time of the council of Ephesus, to exhibit figures of the Virgin and Child became the approved expression of orthodoxy, and the relationship of motherhood in which Mary had been formally declared to stand to God[3] was instinctively felt to give the fullest and freest sanction of the church to that invocation of her aid which had previously been resorted to only hesitatingly and occasionally. Previously to the council of Ephesus, indeed, the practice had obtained complete recognition, so far as we know, in those circles only in which one or other of the numerous redactions of the *Transitus Mariæ* passed current.[4] There we read of Mary's prayer to Christ: "Do Thou bestow Thine aid upon every man calling upon, or praying to, or naming the name of Thine handmaid"; to which His answer is, "Every soul that calls upon thy name shall not be ashamed, but shall find mercy and support and confidence both in the world that now is and in that which is to come in the presence of My Father in the heavens." But Gregory of Nazianzus also, in his panegyric upon Justina, mentions with incidental approval that in her hour of peril she "implored Mary the Virgin to come to the aid of a virgin in her danger."[5] Of the growth of the Marian cultus, alike in the East and in the West, after the decision at Ephesus it would be impossible to trace the history, however slightly, within the limits of the present article. Justinian in one of his laws bespeaks her advocacy for the empire, and he inscribes the high altar in the new church of St Sophia with her name. Narses looks to her for directions on the field of battle. Heraclius bears her image on his banner. John of Damascus speaks of her as the sovereign lady to whom the whole creation has been made subject by her son. Peter Damian recognizes her as the most exalted of all creatures, and apostrophizes her as deified and endowed with all power in heaven and in earth, yet not forgetful of our race.[6] In a word, popular devotion gradually developed the entire system of doctrine and practice which Protestant controversialists are accustomed to call by the name of Mariolatry. With reference to this much-disputed phrase it is always to be kept in mind that the directly authoritative documents,

[1] See Gieseler (*KG.*, Bd. i. Abth. 1), who points out instances in which anti-Arianizing zeal went so far as to call David θεοπάτωρ, and James ἀδελφόθεος.

[2] Labbé, *Conc.*, vol. iii. p. 51. Considerable extracts are given by Augusti (*Denkw.* iii.); see also Milman (*Lat. Christ.*, i. 185), who characterizes much of it as a "wild labyrinth of untranslatable metaphor."

[3] The term θεοτόκος does not actually occur in the canons of Ephesus. It is found, however, in the creed of Chalcedon.

[4] It is true that Irenæus (*Hær.*, v. 19, 1) in the passage in which he draws his well-known parallel and contrast between the first and second Eve (comp. Justin, *Dial. c. Tryph.*, 100), to the effect that, "as the human race fell into bondage to death by a virgin, so is it rescued by a virgin," takes occasion to speak of Mary as the "advocata" of Eve; but it seems certain that this word is a translation of the Greek συνήγορος, and implies hostility and rebuke rather than advocacy.

[5] It is probable that the commemorations and invocations of the Virgin which occur in the present texts of the ancient liturgies of "St James" and "St Mark" are due to interpolation. In this connexion ought also to be noted the chapter in Epiphanius (*Hær.*, 79) against the "Collyridians," certain women in Thrace, Scythia, and Arabia, who were in the habit of worshipping the Virgin (ἀεὶ παρθένον) as a goddess, the offering of a cake (κολλυρίδα τινα) being one of the features of their worship. He rebukes them for offering the worship which was due to the Trinity alone; "let Mary be held in honour, but by no means worshipped." The cultus was probably a relic of heathenism; compare Jerem. xliv. 19.

[6] "Numquid quia ita deificata, ideo nostræ humanitatis oblita es? Nequaquam, Domina. . . . Data est tibi omnis potestas in cœlo et in terra. Nil tibi impossibile" (Serm. de Nativ. Mariæ, ap. Gieseler, *KG.*, Bd. ii. Abth. 1.

alike of the Greek and of the Roman Church, distinguish formally between "latria" and "dulia," and declare that the "worship" to be paid to the mother of God must never exceed that superlative degree of "dulia" which is vaguely described as "hyperdulia." On the other hand, it must be remembered that the comparative reserve shown by the council of Trent in its decrees, and even in its catechism,[1] on this subject has not been observed by individual theologians, and in view of the fact of the canonization of some of these (such as Liguori),—a fact guaranteeing the absence of erroneous teaching from their writings,—it does not seem unfair to hold the Roman Church responsible for the natural interpretations and just inferences which may be drawn even from apparently exaggerated expressions in such works as the well-known *Glories of Mary* and others frequently quoted in controversial literature. A good résumé of recent Catholic developments of the cultus of Mary is to be found in Pusey's *Eirenicon*.

The following are the principal feasts of the Virgin in the order in which they occur in the ecclesiastical year. (1) That of the Presentation (*Præsentatio B. V. M.*, *τὰ εἰσόδια τῆς θεοτόκου*), to commemorate the beginning of her stay in the temple, as recorded in the *Protevangelium Jacobi* (see above). It is believed to have originated in the East sometime in the 8th century, the earliest allusion to it being made by George of Nicomedia (9th century); Manuel Comnenus made it universal for the Eastern empire, and in the modern Greek Church it is one of the five great festivals in honour of the Deipara. It was introduced into the Western Church late in the 14th century, and, after having been withdrawn from the calendar by Pius V., was restored by Sixtus V., the day observed both in East and West being November 21. It is not mentioned in the English calendar. (2) The Feast of the Conception (*Conceptio B. V. M.*, *Conceptio Immaculata B. V. M.*, *σύλληψις τῆς ἁγίας Ἄννης*), observed by the Roman Catholic Church on December 8, and by all the Eastern churches on December 9, has already been explained (see IMMACULATE CONCEPTION); in the Greek Church it only ranks as one of the middle festivals of Mary. (3) The Feast of the Purification (*Occursus, Obvlatio, Præsentatio, Festum SS. Simeonis et Annæ, Purificatio, Candelaria, ὑπαπαντή, ὑπαντή*) is otherwise known as CANDLEMAS (*q.v.*). (4) The Feast of the Annunciation of the Virgin Mary (*Annunciatio, Εὐαγγελισμός*); see ANNUNCIATION. It may be mentioned that at the Toledan council in 656 it was decreed that this festival should be observed on December 18, in order to keep clear of Lent. (5) The Feast of the Visitation (*Visitatio B. V. M.*) was instituted by Urban VI., promulgated in 1389 by Boniface IX., and reappointed by the council of Basel in 1441 in commemoration of the visit paid by Mary to Elizabeth. It is observed on July 2, and has been retained in the English calendar. (6) The Feast of the Assumption (*Dormitio, Pausatio, Transitus, Depositio, Migratio, Assumptio, κοίμησις, μετάστασις, ἀνάληψις*) has reference to the apocryphal story related in several forms in various documents of the 4th century condemned by Pope Gelasius. Their general purport is that as the time drew nigh for "the most blessed Virgin" (who is also spoken of as "Holy Mary," "the queen of all the saints," "the holy spotless Mother of God") to leave the world, the apostles were miraculously assembled round her deathbed at Bethlehem on the Lord's day, whereupon Christ descended with a multitude of angels and received her soul. After "the spotless and precious body" had been laid in the tomb, "suddenly there shone round them (the apostles) a miraculous light," and it was taken up into heaven. The first Catholic writer who relates this story is Gregory of Tours (*c.* 590); Epiphanius two centuries earlier had declared that nothing was known as to the circumstances of Mary's death and burial; and one of the documents of the council of Ephesus implies a belief that she was buried in that city. The Sleep of the Theotokos is observed in the Greek Church as a great festival on August 15; the Armenian Church also commemorates it, but the Ethiopic Church celebrates her death and burial on two separate days. The earliest allusion to the existence of such a festival in the Western Church seems to be that found in the proceedings of the synod of Salzburg in 800; it is also spoken of in the thirty-sixth canon of the reforming synod of Mainz, held in 813. It was not, however, at that time universal, being mentioned as doubtful in the capitularies of Charlemagne. It ought to be observed that the doctrine of the bodily assumption of the Virgin into heaven, although extensively believed, and indeed flowing as natural theological consequence from that of her sinlessness, has never been declared to be "de fide" by the Church of Rome, and is still merely a "pia sententia." (7) The Nativity of Mary (*Nativitas, γενέθλιον τῆς θεοτόκου*), observed on September 8, is first mentioned in one of the homilies of Andrew of Crete (*c.* 750), and along with the feasts of the Purification, the Annunciation, and the Assumption, it was appointed to be observed by the synod of Salzburg in 800, but seems to have been quite unknown at that time in the Gallican Church, and even two centuries later it was by no means general in Italy. In the Roman Church a large number of minor festivals in honour of the Virgin are locally celebrated; and all the Saturdays of the year as well as the entire month of May are also regarded as sacred to her. (J. S. BL.)

[1] The points taught in the catechism are—that she is truly the Mother of God, and the second Eve, by whose means we have received blessing and life; that she is the Mother of Pity, and very specially our advocate; that her merits are highly exalted, and that her dispositions towards us are extremely gracious; that her images are of the utmost utility. In the *Missal* her intercessions (though alluded to in the canon and elsewhere) are seldom directly appealed to except in the Litany and in some of the later offices such as those for September 8, and for the Festival of the Seven Sorrows (decreed by Benedict XIII. in 1727). Noteworthy are the versicles in the office for December 8 (The Feast of the Immaculate Conception), "Tota pulchra es, Maria, et macula originalis non est in te," and "Gloriosa dicta sunt de te, Maria, quia fecit tibi magna qui potens est."

MARY I., queen of England (1516–1558), unpleasantly remembered as "the Bloody Mary" on account of the religious persecutions sanctioned under her reign, was a woman whose private history demands no less compassion than her policy as queen (if indeed it was her own) merits the condemnation of a more humane and tolerant age. She was the daughter of Henry VIII. and Catherine of Aragon, born in the earlier years of their married life, when as yet no cloud had darkened the prospect of Henry's reign. Her birth occurred at Greenwich on Monday the 18th February 1516, and she was baptized on the following Wednesday, Cardinal Wolsey standing as her godfather. She seems to have been a singularly precocious child, and is reported in July 1520, when she was little more than four years of age, as entertaining some visitors by a performance on the virginals. When she was little over nine she was addressed in a complimentary Latin oration by commissioners sent over from Flanders on commercial matters, and replied to them in the same language "with as much assurance and facility as if she had been twelve years old" (Gayangos, iii. pt. 1, 82). Her father, against whom it cannot be said that he depreciated learning, had taken care to give her an excellent education, and was proud of her achievements. About the same time that she replied to the commissioners in Latin he was arranging that she should learn Spanish, Italian, and French. A great part, however, of the credit of her early education was undoubtedly due to her mother, who not only consulted the Spanish scholar Vives upon the subject, but was herself Mary's first teacher in Latin. She was also well instructed in music, and among her principal recreations as she grew up was that of playing on the virginals and lute.

It was a misfortune that she shared with many other high-born ladies in those days that her prospects of life were made a matter of sordid bargaining from the first. Political alliances to be cemented by marriages between persons who were at the time mere infants—or perhaps, more shameful still, between a child and a superannuated debauchee—are among the most repulsive features of the times. Mary was little more than two years old when she was proposed in marriage to the dauphin, son of Francis I. Three years afterwards the French alliance was broken off, and she was affianced to her cousin the young emperor Charles V. by the treaty of Windsor. No one, perhaps, seriously expected either of these arrangements to endure; and, though we read in grave state papers of some curious compliments and love tokens (really the mere counters of diplomacy) professedly sent by the girl of nine to the powerful cousin whom she had never seen, not many years passed away before Charles released himself from this engagement and made a more convenient match. In 1526 a rearrangement was made of the royal household, and it

was thought right to give Mary an establishment of her own along with a council on the borders of Wales, for the better government of the Marches. For some years she accordingly kept her court at Ludlow, while new arrangements were made for the disposal of her hand in connexion with the latest turn in the tortuous game of diplomacy. She was now proposed as a wife, not for the dauphin as before, but for his father Francis I., who had just been redeemed from captivity at Madrid, and who was only too glad of an alliance with England to mitigate the severe conditions imposed on him by the emperor. Wolsey, however, on this occasion, only made use of the princess as a bait to enhance the terms of the compact, and left Francis free in the end to marry the emperor's sister.

It was during this negotiation, as Henry afterwards pretended, that the question was first raised whether Henry's own marriage with Catherine was a lawful one. The bishop of Tarbes, who was one of the ambassadors sent over by Francis to ask the princess in marriage, had, it was said, started an objection that she might possibly be considered illegitimate on account of her mother having been once the wife of her father's brother. The statement was a mere pretence to shield the king when the unpopularity of the divorce became apparent. It is not only extremely improbable in itself, but is proved to be untrue by the strongest evidence, for we have pretty full contemporary records of the whole negotiation. On the contrary, it is quite clear that Henry, who had already for some time conceived the project of a divorce, kept the matter a dead secret, and was particularly anxious that the French ambassadors should not know it, while he used his daughter's hand as a bait for a new alliance. The alliance itself, however, was actually concluded by a treaty dated Westminster, the 30th April 1527, in which it was provided, as regards the Princess Mary, that she should be married either to Francis himself or to his second son Henry, duke of Orleans. But the real object was only to lay the foundation of a perfect mutual understanding between the two kings, which Wolsey soon after went into France to confirm.

During the next nine years the life of Mary, as well as that of her mother, was rendered miserable by the conduct of Henry VIII. in seeking a divorce. During the most of that period mother and daughter seem to have been kept apart, and, though sometimes living at no great distance from each other, were strictly forbidden to see each other. Of the two it may be that Queen Catherine had the hardest trial; but Mary's was scarcely less severe. Removed from court and treated as a bastard, she was, on the birth of Anne Boleyn's daughter, required to give up the dignity of princess and acknowledge the illegitimacy of her own birth. On her refusal her household was broken up, and she was sent to Hatfield to act as lady-in-waiting to her own infant sister. Nor was even this the worst of her trials; her very life was in danger from the hatred of Anne Boleyn. Her health, moreover, was indifferent, and even when she was seriously ill, although Henry sent his own physician Dr Buttes to attend her, he declined to let her mother visit her. So also at her mother's death in January 1536 she was forbidden to take a last farewell of her. But in May following another change occurred which seemed to promise some kind of relief. Anne Boleyn, the real cause of all her miseries, fell under the king's displeasure and was put to death. Mary was then urged to make a humble submission to her father as the means of recovering his favour, and, after a good deal of correspondence with the king's secretary Cromwell, she actually did so. The terms exacted of her were bitter in the extreme, but there was no chance of making life tolerable otherwise, if indeed she was permitted to live at all; and the poor friendless girl, absolutely at the mercy of a father who could brook no contradiction, at length subscribed an act of submission, acknowledging the king as supreme, repudiating the pope's authority, and confessing that the marriage between her father and mother "was by God's law and man's law incestuous and unlawful."

No act, perhaps, in the whole of Henry's reign gives us a more painful idea of his revolting despotism. Mary was a high-spirited girl, and undoubtedly popular. All Europe looked upon her at that time as the only legitimate child of her father, but her father himself compelled her to disown the title and pass an unjust stigma on her own birth and her mother's good name. Nevertheless Henry was now reconciled to her, and gave her a household in some degree suitable to her rank. During the rest of the reign we hear little about her except in connexion with a number of new marriage projects taken up and abandoned successively, one of which, to the count palatine Philip, duke of Bavaria, was specially repugnant to her in the matter of religion. Her privy purse expenses for nearly the whole of this period have been published, and show that Hatfield, Beaulieu or Newhall in Essex, Richmond, and Hunsdon were among her principal places of residence. Although she was still treated as of illegitimate birth, it was believed that the king, having obtained from parliament the extraordinary power to dispose of the crown by will, would restore her to her place in the succession, and three years before his death she was so restored by statute, but still under conditions to be regulated by her father's will.

Under the reign of her brother Edward VI. she was again subjected to severe trials, which at one time made her seriously meditate taking flight and escaping abroad. Edward himself indeed seems to have been personally not unkind to her, but the religious revolution in his reign assumed proportions such as it had not done before, and Mary, who had done sufficient violence to her own convictions in submitting to a despotic father, was not disposed to yield an equally tame obedience to authority exercised by a factious council in the name of a younger brother not yet come to years of discretion. Besides, the cause of the pope was naturally her own. In spite of the forced declaration formerly wrung from herself, no one really regarded her as a bastard, and the full recognition of her rights depended on the recognition of the pope as head of the church. Hence, when Edward's parliament passed an Act of Uniformity enjoining services in English and communion in both kinds, the law appeared to her totally void of authority, and she insisted on having mass in her own private chapel under the old form. When ordered to desist, she appealed for protection to the emperor Charles V., who, being her cousin, intervened for some time not ineffectually, threatening war with England if her religious liberty was interfered with. But Edward's court was composed of factions of which the most violent eventually carried the day. Lord Seymour, the admiral, was attainted of treason and beheaded in 1549. His brother, the Protector Somerset, met with the same fate in 1552. Dudley, duke of Northumberland, then became paramount in the privy council, and easily obtained the sanction of the young king to those schemes for altering the succession which led immediately after his death to the usurpation of Lady Jane Grey. Dudley had, in fact, overawed all the rest of the privy council, and when the event occurred he took such energetic measures to give effect to the scheme that Lady Jane was actually recognized as queen for some days, and Mary had even to fly from Hoddesden into Norfolk. But the country was really devoted to her cause, as indeed her right in law was unquestionable, and before many days she was royally received in London, and took up her abode within the Tower.

Her first acts at the beginning of her reign displayed a character very different from that which she still holds in popular estimation. Her clemency towards those who had taken up arms against her was altogether remarkable. She released from prison Lady Jane's father, Suffolk, and had difficulty even in signing the warrant for the execution of Northumberland. Lady Jane herself she fully meant to spare, and did spare till after Wyatt's formidable insurrection. Her conduct, indeed, was in every respect conciliatory and pacific, and so far as they depended on her personal character the prospects of the new reign might have appeared altogether favourable. But unfortunately her position was one of peculiar difficulty, and the policy on which she determined was far from judicious. Inexperienced in the art of governing, she had no trusty councillor but Gardiner; every other member of the council had been more or less implicated in the conspiracy against her. And though she valued Gardiner's advice she was naturally led to rely even more on that of her cousin, the emperor, who had been her mother's friend in adversity, and had done such material service to herself in the preceding reign. Following the emperor's guidance she determined almost from the first to make his son Philip her husband, though she was eleven years his senior. She was also strongly desirous of restoring the old religion and wiping out the stigma of illegitimacy passed upon her birth, so that she might not seem to reign by virtue of a mere parliamentary settlement.

Each of these different objects was attended by difficulties or objections peculiar to itself; but the marriage was the most unpopular of all. A restoration of the old religion threatened to deprive the new owners of abbey lands of their easy and comfortable acquisitions; and it was only with an express reservation of their interests that the thing was actually accomplished. A declaration of her own legitimacy necessarily cast a slur on that of her sister Elizabeth, and cut her off from the succession. But the marriage promised to throw England into the arms of Spain and place the resources of the kingdom at the command of the emperor's son. The Commons sent her a deputation to entreat that she would not marry a foreigner, and when her resolution was known insurrections broke out in different parts of the country. Suffolk, whose first rebellion had been pardoned, proclaimed Lady Jane Grey again in Leicestershire, while young Wyatt raised the county of Kent and actually besieged the queen in her own palace at Westminster. In the midst of the danger Mary showed great intrepidity, and the rebellion was presently quelled; after which, unhappily, she got leave to pursue her own course unchecked. She married Philip, restored the old religion, and got Cardinal Pole to come over and absolve the kingdom for its past disobedience to the Holy See.

But the misgivings of those who had disliked the Spanish match were more than sufficiently justified by the course of events. Mary yielded a loyal and womanly devotion to a husband who did not too greatly esteem the treasure of her person. Her health, which was feeble before, was bad for the remainder of her days, and she fell under a delusion at first that it was owing to an approaching confinement. Disappointment and vexation probably added to her helplessness. The resources of the kingdom were at Philip's command, and he even took ships of the English fleet to escort his father the emperor, on his abdication, to Spain. More extraordinary still, he ultimately succeeded in committing England to a war against France, when France had made an alliance with the pope against him as king of Spain; so the very marriage which was to confirm England in the old religion led to a war against the occupant of the see of Rome. And it was this war with France which produced the final calamity of the loss of Calais which sank so deeply into Mary's heart some months before she died.

The cruel persecution of the Protestants, which has cast so much infamy upon her reign, began about six months after her marriage; and it is not difficult to see that it was greatly due to the triumph of ideas imported from the land of the Inquisition. Rogers, the first of the martyrs, was burnt on the 4th February 1555. Hooper, bishop of Gloucester, had been condemned six days before, and suffered the same fate upon the 9th. From this time the persecution went on uninterrupted for more than three years, numbering among its victims Ridley, Latimer, and Cranmer. It seems to have been most severe in the eastern and southern parts of England, and the largest number of sufferers was naturally in the diocese of Bonner, bishop of London. From first to last nearly three hundred victims are computed to have perished at the stake; and their fate certainly created a revulsion against Rome that nothing else was likely to have effected. How far Mary herself—who during the most part of this time, if not the whole time, was living in the strictest seclusion, sick in body and mind, hysterical and helpless—was personally answerable for these things, it is difficult to say. To her, no doubt, the propagators of heresy were the enemies of mankind, and she had little cause to love them from her own experience. Yet perhaps she hardly realized the full horror of what was done under her sanction. But there can be little doubt what effect it had upon the people; and when Mary breathed her last, on the 17th November 1558, the event was hailed with joy as a national deliverance. (J. GA.)

MARY II. (1662–1694), queen of England, was the eldest daughter of James, duke of York (afterwards James II. of England), by his first wife Anne Hyde, and was born in London on April 30, 1662. Having been educated in the Protestant faith, she was married to William, prince of Orange, on November 4, 1677. After the events of 1688 she followed her husband to England, and was proclaimed by the convention joint sovereign with him on February 13, 1689. She died of small-pox on December 28, 1694 (o.s.). See Burnet's *Essay upon the Life of Queen Mary*, and the article WILLIAM III.

MARY (1542–1587), queen of Scots, daughter of King James V. and his wife Mary of Lorraine, was born in December 1542, a few days before the death of her father, heart-broken by the disgrace of his arms at Solway Moss, where the disaffected nobles had declined to encounter an enemy of inferior force in the cause of a king whose systematic policy had been directed against the privileges of their order, and whose representative on the occasion was an unpopular favourite appointed general in defiance of their ill-will. On the 9th of September following the ceremony of coronation was duly performed upon the infant. A scheme for her betrothal to Edward, prince of Wales, was defeated by the grasping greed of his father, whose obvious ambition to annex the crown of Scotland at once to that of England aroused instantly the general suspicion and indignation of Scottish patriotism. In 1548 the queen of six years old was betrothed to the dauphin Francis, and set sail for France, where she arrived on the 15th of August. The society in which the child was thenceforward reared is known to readers of Brantôme as well as that of imperial Rome at its worst is known to readers of Suetonius or Petronius,—as well as that of papal Rome at its worst is known to readers of the diary kept by the domestic chaplain of Pope Alexander VI. Only in their pages can a parallel be found to the gay and easy record which reveals without sign of shame or suspicion of offence the daily life of a court compared to which the court

of King Charles II. is as the court of Queen Victoria to the society described by Grammont. Debauchery of all kinds, and murder in all forms, were the daily matter of excitement or of jest to the brilliant circle which revolved around Queen Catherine de' Medici. After ten years' training under the tutelage of the woman whose main instrument of policy was the corruption of her own children, the queen of Scots, aged fifteen years and five months, was married to the eldest and feeblest of the brood on April 24, 1558. On the 17th of November Elizabeth became queen of England, and the princes of Lorraine—Francis the great duke of Guise, and his brother the cardinal—induced their niece and her husband to assume, in addition to the arms of France and Scotland, the arms of a country over which they asserted the right of Mary Stuart to reign as legitimate heiress of Mary Tudor. Civil strife broke out in Scotland between John Knox and the queen-dowager,—between the self-styled "congregation of the Lord" and the adherents of the regent, whose French troops repelled the combined forces of the Scotch and their English allies from the beleaguered walls of Leith, little more than a month before the death of their mistress in the castle of Edinburgh, on the 10th of June 1560. On the 25th of August Protestantism was proclaimed and Catholicism suppressed in Scotland by a convention of states assembled without the assent of the absent queen. On the 5th of December Francis II. died; in August 1561 his widow left France for Scotland, having been refused a safe-conduct by Elizabeth on the ground of her own previous refusal to ratify the treaty made with England by her commissioners in the same month of the preceding year. She arrived nevertheless in safety at Leith, escorted by three of her uncles of the house of Lorraine, and bringing in her train her future biographer, Brantôme, and Chastelard, the first of all her voluntary victims. On the 21st of August she first met the only man able to withstand her; and their first passage of arms left, as he has recorded, upon the mind of John Knox an ineffaceable impression of her "proud mind, crafty wit, and indurate heart against God and His truth." And yet her acts of concession and conciliation were such as no fanatic on the opposite side could have approved. She assented, not only to the undisturbed maintenance of the new creed, but even to a scheme for the endowment of the Protestant ministry out of the confiscated lands of the Church. Her half-brother, Lord James Stuart, shared the duties of her chief counsellor with William Maitland of Lethington, the keenest and most liberal thinker in the country. By the influence of Lord James, in spite of the earnest opposition of Knox, permission was obtained for her to hear mass celebrated in her private chapel,—a licence to which, said the Reformer, he would have preferred the invasion of ten thousand Frenchmen. Through all the first troubles of her reign the young queen steered her skilful and dauntless way with the tact of a woman and the courage of a man. An insurrection in the north, headed by the earl of Huntly under pretext of rescuing from justice the life which his son had forfeited by his share in a homicidal brawl, was crushed at a blow by the Lord James against whose life, as well as against his sister's liberty, the conspiracy of the Gordons had been aimed, and on whom, after the father had fallen in fight and the son had expiated his double offence on the scaffold, the leading rebel's earldom of Murray was conferred by the gratitude of the queen. Exactly four months after the battle of Corrichie, and the subsequent execution of a criminal whom she is said to have "loved entirely," had put an end to the first insurrection raised against her, Pierre de Boscosel de Chastelard, who had returned to France with the other companions of her arrival, and in November 1562 had revisited Scotland, expiated with his head the offence or the misfortune of a second detection at night in her bed-chamber. In the same month, twenty-five years afterwards, the execution of his mistress, according to the verdict of her contemporaries in France, avenged the blood of a lover who had died without uttering a word to realize the apprehension which (according to Knox) had before his trial impelled her to desire her brother "that, as he loved her, he would slay Chastelard, and let him never speak word." And in the same month, two years from the date of Chastelard's execution, her first step was unconsciously taken on the road to Fotheringay, when she gave her heart at first sight to her kinsman Henry, Lord Darnley, son of Matthew Stuart, earl of Lennox, who had suffered an exile of twenty years in expiation of his intrigues with England, and had married the niece of King Henry VIII., daughter of his sister Margaret, the widow of James IV., by her second husband, the earl of Angus. Queen Elizabeth, with the almost incredible want of tact or instinctive delicacy which distinguished and disfigured her vigorous intelligence, had recently proposed as a suitor to the queen of Scots her own low-born favourite, Lord Robert Dudley, the widower if not the murderer of Amy Robsart; and she now protested against the project of marriage between Mary and Darnley. Mary, who had already married her kinsman in secret at Stirling Castle with Catholic rites celebrated in the apartment of David Rizzio, her secretary for correspondence with France, assured the English ambassador, in reply to the protest of his mistress, that the marriage would not take place for three months, when a dispensation from the pope would allow the cousins to be publicly united without offence to the church. On the 29th of July 1565 they were accordingly remarried at Holyrood. The hapless and worthless bridegroom had already incurred the hatred of two powerful enemies, the earls of Morton and Glencairn; but the former of these took part with the queen against the forces raised by Murray, Glencairn, and others, under the nominal leadership of Hamilton, duke of Chatelherault, on the double plea of danger to the new religion of the country, and of the illegal proceeding by which Darnley had been proclaimed king of Scots without the needful constitutional assent of the estates of the realm. Murray was cited to attend the "raid" or array levied by the king and queen, and was duly denounced by public blast of trumpet for his non-appearance. He entered Edinburgh with his forces, but failed to hold the town against the guns of the castle, and fell back upon Dumfries before the advance of the royal army which was now joined by James Hepburn, earl of Bothwell, on his return from a three years' outlawed exile in France. He had been accused in 1562 of a plot to seize the queen and put her into the keeping of the earl of Arran, whose pretensions to her hand ended only when his insanity could no longer be concealed. Another new adherent was the son of the late earl of Huntly, to whom the forfeited honours of his house were restored a few months before the marriage of his sister to Bothwell. The queen now appealed to France for aid; but Castelnau, the French ambassador, replied to her passionate pleading by sober and earnest advice to make peace with the malcontents. This counsel was rejected, and in October 1565 the queen marched an army of 18,000 men against them from Edinburgh; their forces dispersed in face of superior numbers, and Murray, on seeking shelter in England, was received with contumely by Elizabeth, whose half-hearted help had failed to support his enterprise, and whose intercession for his return found at first no favour with the queen of Scots. But the conduct of the besotted boy on whom at their marriage she had bestowed the title of king began at once to justify the

enterprise and to play into the hands of all his enemies alike. His father set him on to demand the crown matrimonial, which would at least have assured to him the rank and station of independent royalty for life. Rizzio, hitherto his friend and advocate, induced the queen to reply by a reasonable refusal to this hazardous and audacious request. Darnley at once threw himself into the arms of the party opposed to the policy of the queen and her secretary,—a policy which at that moment was doubly and trebly calculated to exasperate the fears of the religious and the pride of the patriotic. Mary was invited if not induced by the king of Spain to join his league for the suppression of Protestantism; while the actual or prospective endowment of Rizzio with Morton's office of chancellor, and the projected attainder of Murray and his allies, combined to inflame at once the anger and the apprehension of the Protestant nobles. According to one account, Darnley privately assured his uncle George Douglas of his wife's infidelity; he had himself, if he might be believed, discovered the secretary in the queen's apartment at midnight, under circumstances yet more unequivocally compromising than those which had brought Chastelard to the scaffold. Another version of the pitiful history represents Douglas as infusing suspicion of Rizzio into the empty mind of his nephew, and thus winning his consent to a deed already designed by others. A bond was drawn in which Darnley pledged himself to support the confederates who undertook to punish "certain privy persons" offensive to the state, "especially a stranger Italian called Davie"; another was subscribed by Darnley and the banished lords, then biding their time in Newcastle, which engaged him to procure their pardon and restoration, while pledging them to ensure to him the enjoyment of the title he coveted, with the consequent security of an undisputed succession to the crown, despite the counter claims of the house of Hamilton, in case his wife should die without issue,—a result which, intentionally or not, he and his fellow conspirators did all that brutality could have suggested to accelerate and secure. On the 9th of March the palace of Holyrood was invested by a troop under the command of Morton, while Rizzio was dragged by force out of the queen's presence and slain without trial in the heat of the moment. The parliament was discharged by proclamation issued in the name of Darnley as king; and in the evening of the next day the banished lords, whom it was to have condemned to outlawry, returned to Edinburgh. On the day following they were graciously received by the queen, who undertook to sign a bond for their security, but delayed the subscription till next morning under plea of sickness. During the night she escaped with Darnley, whom she had already seduced from the party of his accomplices, and arrived at Dunbar on the third morning after the slaughter of her favourite. From thence they returned to Edinburgh on the 28th of March, guarded by two thousand horsemen under the command of Bothwell, who had escaped from Holyrood on the night of the murder, to raise a force on the queen's behalf with his usual soldierly promptitude. The slayers of Rizzio fled to England, and were outlawed; Darnley was permitted to protest his innocence and denounce his accomplices; after which he became the scorn of all parties alike, and few men dared or cared to be seen in his company. On the 19th of June a son was born to his wife, and in the face of his previous protestations he was induced to acknowledge himself the father. But, as Murray and his partisans returned to favour and influence no longer incompatible with that of Bothwell and Huntly, he grew desperate enough with terror to dream of escape to France. This design was at once frustrated by the queen's resolution. She summoned him to declare his reasons for it in presence of the French ambassador and an assembly of the nobles; she besought him for God's sake to speak out, and not spare her; and at last he left her presence with an avowal that he had nothing to allege. The favour shown to Bothwell had not yet given occasion for scandal, though his character as an adventurous libertine was as notable as his reputation for military hardihood; but as the summer advanced his insolence increased with his influence at court and the general aversion of his rivals. He was richly endowed by Mary from the greater and lesser spoils of the church; and the three wardenships of the border, united for the first time in his person, gave the lord high admiral of Scotland a position of unequalled power. In the gallant discharge of its duties he was dangerously wounded by a leading outlaw, whom he slew in single combat; and while yet confined to Hermitage Castle he received a visit of two hours from the queen, who rode thither from Jedburgh and back through 20 miles of the wild borderland, where her person was in perpetual danger from the freebooters whom her father's policy had striven and had failed to extirpate. The result of this daring ride was a ten days' fever, after which she removed by short stages to Craigmillar, where a proposal for her divorce from Darnley was laid before her by Bothwell, Murray, Huntly, Argyle, and Lethington, who was chosen spokesman for the rest. She assented on condition that the divorce could be lawfully effected without impeachment of her son's legitimacy; whereupon Lethington undertook in the name of all present that she should be rid of her husband without any prejudice to the child,—at whose baptism a few days afterwards Bothwell took the place of the putative father, though Darnley was actually residing under the same roof, and it was not till after the ceremony that he was suddenly struck down by a sickness so violent as to excite suspicions of poison. He was removed to Glasgow, and left for the time in charge of his father; but on the news of his progress towards recovery a bond was drawn up for execution of the sentence of death which had secretly been pronounced against the twice-turned traitor who had earned his doom at all hands alike. On the 22d of the next month (January 1567) the queen visited her husband at Glasgow and proposed to remove him to Craigmillar Castle, where he would have the benefit of medicinal baths; but instead of this resort he was conveyed on the last day of the month to the lonely and squalid shelter of the residence which was soon to be made memorable by his murder. Between the ruins of two sacred buildings, with the town-wall to the south and a suburban hamlet known to ill fame as the Thieves' Row to the north of it, a lodging was prepared for the titular king of Scotland, and fitted up with tapestries taken from the Gordons after the battle of Corrichie. On the evening of Sunday, February 9, Mary took her last leave of the miserable boy who had so often and so mortally outraged her as consort and as queen. That night the whole city was shaken out of sleep by an explosion of gunpowder which shattered to fragments the building in which he should have slept and perished; and next morning the bodies of Darnley and a page were found strangled in a garden adjoining it, whither they had apparently escaped over a wall, to be despatched by the hands of Bothwell's attendant confederates.

Upon the view which may be taken of Mary's conduct during the next three months depends the whole debatable question of her character. According to the professed champions of that character, this conduct was a tissue of such dastardly imbecility, such heartless irresolution, and such brainless inconsistency as for ever to dispose of her time-honoured claim to the credit of intelligence and courage. It is certain that just three months and six days after the murder of her husband she became the wife of

her husband's murderer. On the 11th of February she wrote to the bishop of Glasgow, her ambassador in France, a brief letter of simple eloquence, announcing her providential escape from a design upon her own as well as her husband's life. A reward of two thousand pounds was offered by proclamation for discovery of the murderer. Bothwell and others, his satellites or the queen's, were instantly placarded by name as the criminals. Voices were heard by night in the streets of Edinburgh calling down judgment on the assassins. Four days after the discovery of the bodies, Darnley was buried in the chapel of Holyrood with secrecy as remarkable as the solemnity with which Rizzio had been interred there less than a year before. On the Sunday following, Mary left Edinburgh for Seton Palace, 12 miles from the capital, where scandal asserted that she passed the time merrily in shooting-matches with Bothwell for her partner against Lords Seton and Huntly; other accounts represent Huntly and Bothwell as left at Holyrood in charge of the infant prince. Gracefully and respectfully, with statesmanlike yet feminine dexterity, the demands of Darnley's father for justice on the murderers of his son were accepted and eluded by his daughter-in-law. Bothwell, with a troop of fifty men, rode through Edinburgh defiantly denouncing vengeance on his concealed accusers. As weeks elapsed without action on the part of the royal widow, while the cry of blood was up throughout the country, raising echoes from England and abroad, the murmur of accusation began to rise against her also. Murray, with his sister's ready permission, withdrew to France. Already the report was abroad that the queen was bent on marriage with Bothwell, whose last year's marriage with the sister of Huntly would be dissolved, and the assent of his wife's brother purchased by the restitution of his forfeited estates. According to the *Memoirs* of Sir James Melville, both Lord Herries and himself resolved to appeal to the queen in terms of bold and earnest remonstrance against so desperate and scandalous a design; Herries, having been met with assurances of its unreality and professions of astonishment at the suggestion, instantly fled from court; Melville, evading the danger of a merely personal protest without backers to support him, laid before Mary a letter from a loyal Scot long resident in England, which urged upon her consideration and her conscience the danger and disgrace of such a project yet more freely than Herries had ventured to do by word of mouth; but the sole result was that it needed all the queen's courage and resolution to rescue him from the violence of the man for whom, she was reported to have said, she cared not if she lost France, England, and her own country, and would go with him to the world's end in a white petticoat before she would leave him. On the 28th of March the privy council, in which Bothwell himself sat, appointed the 12th of April as the day of his trial, Lennox, instead of the crown, being named as the accuser, and cited by royal letters to appear at "the humble request and petition of the said Earl Bothwell," who, on the day of the trial, had four thousand armed men behind him in the streets, while the castle was also at his command. Under these arrangements it was not thought wonderful that Lennox discreetly declined the danger of attendance, even with three thousand men ready to follow him, at the risk of desperate street fighting. He pleaded sickness, asked for more time, and demanded that the accused, instead of enjoying special favour, should share the treatment of other suspected criminals. But, as no particle of evidence on his side was advanced, the protest of his representative was rejected, and Bothwell, acquitted in default of witnesses against him, was free to challenge any persistent accuser to the ancient ordeal of battle. His wealth and power were enlarged by gift of the parliament which met on the 14th and rose on the 19th of April,—a date made notable by the subsequent supper at Ainslie's tavern, where Bothwell obtained the signatures of its leading members to a document affirming his innocence, and pledging the subscribers to maintain it against all challengers, to stand by him in all his quarrels, and finally to promote by all means in their power the marriage by which they recommended the queen to reward his services, and benefit the country. On the second day following Mary went to visit her child at Stirling, where his guardian, the earl of Mar, refused to admit more than two women in her train. It was well known in Edinburgh that Bothwell had a body of men ready to intercept her on the way back, and carry her to Dunbar,—not, as was naturally inferred, without good assurance of her consent. On the 24th of April, as she approached Edinburgh, Bothwell accordingly met her at the head of eight hundred spearmen, assured her (as she afterwards averred) that she was in the utmost peril, and escorted her, together with Huntly, Lethington, and Melville, who were then in attendance, to Dunbar Castle. On the 3d of May Lady Jane Gordon, who had become countess of Bothwell on February 22d of the year preceding, obtained, on the ground of her husband's infidelities, a separation which, however, would not under the old laws of Catholic Scotland have left him free to marry again; on the 7th, accordingly, the necessary divorce was pronounced, after two days' session, by a clerical tribunal which ten days before had received from the queen a special commission to give judgment on a plea of somewhat apocryphal consanguinity alleged by Bothwell as the ground of an action for divorce against his wife. The fact was studiously evaded or concealed that a dispensation had been granted by the archbishop of St Andrews for this irregularity, which could only have arisen through some illicit connexion of the husband with a relative of the wife between whom and himself no affinity by blood or marriage could be proved. On the day when the first or Protestant divorce was pronounced, Mary and Bothwell returned to Edinburgh with every prepared appearance of a peaceful triumph. Lest her captivity should have been held to invalidate the late legal proceedings in her name, proclamation was made of forgiveness accorded by the queen to her captor in consideration of his past and future services, and her intention was announced to reward them by further promotion; and on the same day (May 12th) he was duly created duke of Orkney and Shetland. The duke, as a conscientious Protestant, refused to marry his mistress according to the rites of her church; and she, the chosen champion of its cause, agreed to be married to him, not merely by a Protestant, but by one who before his conversion had been a Catholic bishop, and should therefore have been more hateful and contemptible in her eyes than any ordinary heretic, had not religion as well as policy, faith as well as reason, been absorbed or superseded by some more mastering passion or emotion. This passion or emotion, according to those who deny her attachment to Bothwell, was simply terror,—the blind and irrational prostration of an abject spirit before the cruel force of circumstances and the crafty wickedness of men. Hitherto, according to all evidence, she had shown herself on all occasions, as on all subsequent occasions she indisputably showed herself, the most fearless, the most keen-sighted, the most ready-witted, the most high-gifted and high-spirited of women; gallant and generous, skilful and practical, never to be cowed by fortune, never to be cajoled by craft; neither more unselfish in her ends nor more unscrupulous in her practice than might have been expected from her training and her creed. But at the crowning moment of trial there are those who assert their belief that the woman who on her way to the field of Corrichie had

uttered her wish to be a man, that she might know all the hardship and all the enjoyment of a soldier's life, riding forth "in jack and knapscull"—the woman who long afterwards was to hold her own for two days together without help of counsel against all the array of English law and English statesmanship, armed with irrefragable evidence and supported by the resentment of a nation—showed herself equally devoid of moral and of physical resolution; too senseless to realize the significance and too heartless to face the danger of a situation from which the simplest exercise of reason, principle, or courage must have rescued the most unsuspicious and inexperienced of honest women who was not helplessly deficient in self-reliance and self-respect. The famous correspondence produced next year in evidence against her at the conference of York may have been, as her partisans affirm, so craftily garbled and falsified by interpolation, suppression, perversion, or absolute forgery as to be all but historically worthless. Its acceptance or its rejection does not in any degree whatever affect, for better or for worse, the rational estimate of her character. The problem presented by the simple existence of the facts just summed up remains in either case absolutely the same.

That the coarse and imperious nature of the hardy and able ruffian who had now become openly her master should no less openly have shown itself even in the first moments of their inauspicious union is what any bystander of common insight must inevitably have foreseen. Tears, dejection, and passionate expressions of a despair "wishing only for death," bore fitful and variable witness to her first sense of a heavier yoke than yet had galled her spirit and her pride. At other times her affectionate gaiety would give evidence as trustworthy of a fearless and improvident satisfaction. They rode out in state together, and if he kept cap in hand as a subject she would snatch it from him and clap it on his head again; while in graver things she took all due or possible care to gratify his ambition, by the insertion of a clause in their contract of marriage which made their joint signature necessary to all documents of state issued under the sign-manual. She despatched to France a special envoy, the bishop of Dumblane, with instructions setting forth at length the unparalleled and hitherto ill-requited services and merits of Bothwell, and the necessity of compliance at once with his passion and with the unanimous counsel of the nation,—a people who would endure the rule of no foreign consort, and whom none of their own countrymen were so competent to control, alike by wisdom and by valour, as the incomparable subject of her choice. These personal merits and this political necessity were the only pleas advanced in a letter to her ambassador in England. But that neither plea would avail her for a moment in Scotland she had ominous evidence on the thirteenth day after her marriage, when no response was made to the usual form of proclamation for a raid or levy of forces under pretext of a campaign against the rievers of the border. On the 6th or 7th of June Mary and Bothwell took refuge in Borthwick Castle, twelve miles from the capital, where the fortress was in the keeping of an adherent whom the diplomacy of Sir James Melville had succeeded in detaching from his allegiance to Bothwell. The fugitives were pursued and beleaguered by the earl of Morton and Lord Hume, who declared their purpose to rescue the queen from the thraldom of her husband. He escaped, leaving her free to follow him or to join the party of her professed deliverers. But whatever cause she might have found since marriage to complain of his rigorous custody and domineering brutality was insufficient to break the ties by which he held her. Alone, in the disguise of a page, she slipped out of the castle at midnight, and rode off to meet him at a tower two miles distant, whence they fled together to Dunbar. The confederate lords on entering Edinburgh were welcomed by the citizens, and after three hours' persuasion Lethington, who had now joined them, prevailed on the captain of the castle to deliver it also into their hands. Proclamations were issued in which the crime of Bothwell was denounced, and the disgrace of the country, the thraldom of the queen, and the mortal peril of her infant son were set forth as reasons for summoning all the lieges of the chief cities of Scotland to rise in arms on three hours' notice and join the forces assembled against the one common enemy. News of his approach reached them on the night of June 14, and they marched before dawn with 2200 men to meet him near Musselburgh. Mary meanwhile had passed from Dunbar to Haddington, and thence to Seton, where 1600 men rallied to her side. On the 15th of June, one month from their marriage day, the queen and Bothwell, at the head of a force of fairly equal numbers but visibly inferior discipline, met the army of the confederates at Carberry Hill, some six miles from Edinburgh. Du Croc, the French ambassador, obtained permission through the influence of Maitland to convey to the queen the terms proposed by their leaders,—that she and Bothwell should part, or that he should meet in single combat a champion chosen from among their number. Bothwell offered to meet any man of sufficient quality; Mary would not assent. As the afternoon wore on their force began to melt away by desertion and to break up for lack of discipline. Again the trial by single combat was proposed, and thrice the proposal fell through, owing to objections on this side or on that. At last it was agreed that the queen should yield herself prisoner, and Bothwell be allowed to retire in safety to Dunbar with the few followers who remained to him. Mary took leave of her first and last master with passionate anguish and many parting kisses; but in face of his enemies, and in hearing of the cries which burst from the ranks, demanding her death by fire as a murderess and harlot, the whole heroic and passionate spirit of the woman represented by her admirers as a spiritless imbecile flamed out in responsive threats to have all the men hanged and crucified, in whose power she now stood helpless and alone. She grasped the hand of Lord Lindsay as he rode beside her, and swore "by this hand" she would "have his head for this." In Edinburgh she was received by a yelling mob, which flaunted before her at each turn a banner representing the corpse of Darnley with her child beside it invoking on his knees the retribution of Divine justice. From the violence of a multitude in which women of the worst class were more furious than the men she was sheltered in the house of the provost, where she repeatedly showed herself at the window, appealing aloud with dishevelled hair and dress to the mercy which no man could look upon her and refuse. At nine in the evening she was removed to Holyrood, and thence to the port of Leith, where she embarked under guard, with her attendants, for the island castle of Lochleven. On the 20th a silver casket containing letters and French verses, miscalled sonnets, in the handwriting of the queen, was taken from the person of a servant who had been sent by Bothwell to bring it from Edinburgh to Dunbar. Even in the existing versions of the letters, translated from the lost originals and retranslated from this translation of a text which was probably destroyed in 1603 by order of King James on his accession to the English throne,—even in these possibly disfigured versions, the fiery pathos of passion, the fierce and piteous fluctuations of spirit between love and hate, hope and rage and jealousy, have an eloquence apparently beyond the imitation or invention of art. Three days after this discovery Lord Lindsay, Lord Ruthven, and Sir Robert Melville were despatched to

Lochleven, there to obtain the queen's signature to an act of abdication in favour of her son, and another appointing Murray regent during his minority. She submitted, and a commission of regency was established till the return from France of Murray, who, on the 15th of August, arrived at Lochleven with Morton and Athole. According to his own account, the expostulations as to her past conduct which preceded his admonitions for the future were received with tears, confessions, and attempts at extenuation or excuse; but when they parted next day on good terms she had regained her usual spirits. Nor from that day forward had they reason to sink again, in spite of the close keeping in which she was held, with the daughters of the house for bedfellows. Their mother and the regent's, her father's former mistress, was herself not impervious to her prisoner's lifelong power of seduction and subjugation. Her son George Douglas fell inevitably under the charm. A rumour transmitted to England went so far as to assert that she had proposed him to their common half-brother Murray as a fourth husband for herself; a later tradition represented her as the mother of a child by him. A third report, at least as improbable as either, asserted that a daughter of Mary and Bothwell, born about this time, lived to be a nun in France. It is certain that the necessary removal of George Douglas from Lochleven enabled him to devise a method of escape for the prisoner on March 25, 1568, which was frustrated by detection of her white hands under the disguise of a laundress. But a younger member of the household, Willie Douglas, aged eighteen, whose devotion was afterwards remembered and his safety cared for by Mary at a time of utmost risk and perplexity to herself, succeeded on May 2d in assisting her to escape by a postern gate to the lake-side, and thence in a boat to the main land, where George Douglas, Lord Seton, and others were awaiting her. Thence they rode to Seton's castle of Niddry, and next day to Hamilton Palace, round which an army of 6000 men was soon assembled, and whither the new French ambassador to Scotland hastened to pay his duty. The queen's abdication was revoked, messengers were despatched to the English and French courts, and word was sent to Murray at Glasgow that he must resign the regency, and should be pardoned in common with all offenders against the queen. But on the day when Mary arrived at Hamilton Murray had summoned to Glasgow the feudatories of the crown, to take arms against the insurgent enemies of the infant king. Elizabeth sent conditional offers of help to her kinswoman, provided she would accept of English intervention and abstain from seeking foreign assistance; but the messenger came too late. Mary's followers had failed to retake Dunbar Castle from the regent, and made for Dumbarton instead, marching two miles south of Glasgow, by the village of Langside. Here Murray, with 4500 men, under leaders of high distinction, met the 6000 of the queen's army, whose ablest man, Herries, was as much distrusted by Mary as by every one else, while the Hamiltons could only be trusted to think of their own interests, and were suspected of treasonable designs on all who stood between their house and the monarchy. On the 13th of May the battle or skirmish of Langside determined the result of the campaign in three quarters of an hour. Kirkaldy of Grange, who commanded the regent's cavalry, seized and kept the place of vantage from the beginning, and at the first sign of wavering on the other side shattered at a single charge the forces of the queen, with a loss of one man to three hundred. Mary fled 60 miles from the field of her last battle before she halted at Sanquhar, and for three days of flight, according to her own account, had to sleep on the hard ground, live on oatmeal and sour milk, and fare at night like the owls, in hunger, cold, and fear. On the third day from the rout of Langside she crossed the Solway, and landed at Workington in Cumberland, May 16, 1568. On the 20th Lord Scrope and Sir Francis Knollys were sent from court to carry messages and letters of comfort from Elizabeth to Mary at Carlisle. On June 11th Knollys wrote to Cecil at once the best description and the noblest panegyric extant of the queen of Scots,—enlarging, with a brave man's sympathy, on her indifference to form and ceremony, her daring grace and openness of manner, her frank display of a great desire to be avenged of her enemies, her readiness to expose herself to all perils in hope of victory, her delight to hear of hardihood and courage, commending by name all her enemies of approved valour, sparing no cowardice in her friends, but above all things athirst for victory by any means at any price, so that for its sake pain and peril seemed pleasant to her, and wealth and all things, if compared with it, contemptible and vile. What was to be done with such a princess, whether she were to be nourished in one's bosom, above all whether it could be advisable or safe to try any diplomatic tricks upon such a lady, Knollys left for the minister to judge. It is remarkable that he should not have discovered in her the qualities so obvious to modern champions of her character,—easiness, gullibility, incurable innocence and invincible ignorance of evil, incapacity to suspect or resent anything, readiness to believe and forgive all things. On the 15th of July, after various delays interposed by her reluctance to leave the neighbourhood of the border, where on her arrival she had received the welcome and the homage of the leading Catholic houses of Northumberland and Cumberland, she was removed to Bolton Castle in North Yorkshire. During her residence here a conference was held at York between her own and Elizabeth's commissioners and those appointed to represent her son as king of Scots. These latter, of whom Murray himself was the chief, privately laid before the English commissioners the contents of the famous casket. On the 24th of October the place of the conference was shifted from York to London, where the inquiry was to be held before Queen Elizabeth in council. Mary was already aware that the chief of the English commissioners, the duke of Norfolk, was secretly an aspirant to the peril of her hand; and on October 21st she gave the first sign of assent to the suggestion of a divorce from Bothwell. On the 26th of October the charge of complicity in the murder of Darnley was distinctly brought forward against her in spite of Norfolk's reluctance and Murray's previous hesitation. Elizabeth, by the mouth of her chief justice, formally rebuked the audacity of the subjects who durst bring such a charge against their sovereign, and challenged them to advance their proofs. They complied by the production of an indictment under five heads, supported by the necessary evidence of documents. The number of English commissioners was increased, and they were bound to preserve secrecy as to the matters revealed. Further evidence was supplied by Thomas Crawford, a retainer of the house of Lennox, tallying so exactly with the text of the casket letters as to have been cited in proof that the latter must needs be a forgery. Elizabeth, on the close of the evidence, invited Mary to reply to the proofs alleged before she could be admitted to her presence; but Mary simply desired her commissioners to withdraw from the conference. She declined with scorn the proposal made by Elizabeth through Knollys, that she should sign a second abdication in favour of her son. On January 10, 1569, the judgment given at the conference acquitted Murray and his adherents of rebellion, while affirming that nothing had been proved against Mary,—a verdict accepted by Murray as equivalent to a practical recognition of his office as regent for the infant king. This position he was not long to hold; and the fierce exultation of Mary at the

news of his murder gave to those who believed in her complicity with the murderer, on whom a pension was bestowed by her unblushing gratitude, fresh reason to fear, if her liberty of correspondence and intrigue were not restrained, the likelihood of a similar fate for Elizabeth. On January 26, 1569, she had been removed from Bolton Castle to Tutbury in Staffordshire, where proposals were conveyed to her, at the instigation of Leicester, for a marriage with the duke of Norfolk, to which she gave a graciously conditional assent; but the discovery of these proposals consigned Norfolk to the Tower, and on the outbreak of an insurrection in the north Mary, by Lord Hunsdon's advice, was again removed to Coventry, when a body of her intending deliverers was within a day's ride of Tutbury. On the 23d of January following Murray was assassinated; and a second northern insurrection was crushed in a single sharp fight by Lord Hunsdon. In October Cecil had an interview with Mary at Chatsworth, when the conditions of her possible restoration to the throne in compliance with French demands were debated at length. The queen of Scots, with dauntless dignity, refused to yield the castles of Edinburgh and Dumbarton into English keeping, or to deliver up her fugitive English partisans then in Scotland; upon other points they came to terms, and the articles were signed October 16. On the same day Mary wrote to Elizabeth, requesting with graceful earnestness the favour of an interview which might reassure her against the suggestion that this treaty was a mere pretence. On November 28 she was removed to Sheffield Castle, where she remained for the next fourteen years in charge of the earl of Shrewsbury. The detection of a plot, in which Norfolk was implicated, for the invasion of England by Spain on behalf of Mary, who was then to take him as the fourth and most contemptible of her husbands, made necessary the reduction of her household and the stricter confinement of her person. On May 28, 1572, a demand from both houses of parliament for her execution as well as Norfolk's was generously rejected by Elizabeth; but after the punishment of the traitorous pretender to her hand, on whom she had lavished many eloquent letters of affectionate protestation, she fell into "a passion of sickness" which convinced her honest keeper of her genuine grief for the ducal caitiff. A treaty projected on the news of the massacre of St Bartholomew, by which Mary should be sent back to Scotland for immediate execution, was broken off by the death of the earl of Mar, who had succeeded Lennox as regent; nor was it found possible to come to acceptable terms on a like understanding with his successor Morton, who in 1577 sent a proposal to Mary for her restoration, which she declined, in suspicion of a plot laid to entrap her by the policy of Sir Francis Walsingham, the most unscrupulously patriotic of her English enemies, who four years afterwards sent word to Scotland that the execution of Morton, so long the ally of England, would be answered by the execution of Mary. But on that occasion Elizabeth again refused her assent either to the trial of Mary or to her transference from Sheffield to the Tower. In 1581 Mary accepted the advice of Catherine de' Medici and Henry III. that she should allow her son's title to reign as king of Scotland conjointly with herself when released and restored to a share of the throne. This plan was but part of a scheme including the invasion of England by her kinsman the duke of Guise, who was to land in the north and raise a Scottish army to place the released prisoner of Sheffield beside her son on the throne of Elizabeth. After the overthrow of the Scottish accomplices in this notable project, Mary poured forth upon Elizabeth a torrent of pathetic and eloquent reproach for the many wrongs she had suffered at the hands of her hostess, and pledged her honour to the assurance that she now aspired to no kingdom but that of heaven. In the spring of 1583 she retained enough of this saintly resignation to ask for nothing but liberty, without a share in the government of Scotland; but Lord Burghley not unreasonably preferred, if feasible, to reconcile the alliance of her son with the detention of his mother. In 1584 the long-suffering earl of Shrewsbury was relieved of his fourteen years' charge through the involuntary good offices of his wife, whose daughter by her first husband had married a brother of Darnley; and their orphan child Arabella, born in England, of royal descent on the father's side, was now, in the hopeful view of her grandmother, a more plausible claimant than the king or queen of Scots to the inheritance of the English throne. In December 1583 Mary had laid before the French ambassador her first complaint of the slanders spread by Lady Shrewsbury and her sons, who were ultimately compelled to confess the falsehood of their imputations on the queen of Scots and her keeper. It was probably at the time when a desire for revenge on her calumniatress made her think the opportunity good and safe for discharge of such a two-edged dart at the countess and the queen that Mary wrote, but abstained from despatching, the famous and terrible letter in which, with many gracious excuses and professions of regret and attachment, she transmits to Elizabeth a full and vivid report of the hideous gossip retailed by Bess of Hardwick regarding her character and person at a time when the reporter of these abominations was on friendly terms with her husband's royal charge. In the autumn of 1584 she was removed to Wingfield Manor under charge of Sir Ralph Sadler and John Somers, who accompanied her also on her next removal to Tutbury in January 1585. A letter received by her in that cold, dark, and unhealthy castle, of which fifteen years before she had made painful and malodorous experience, assured her that her son would acknowledge her only as queen-mother, and provoked at once the threat of a parent's curse and an application to Elizabeth for sympathy. In April 1585 Sir Amyas Paulet was appointed to the office of which Sadler, accused of careless indulgence, had requested to be relieved; and on Christmas Eve she was removed from the hateful shelter of Tutbury to the castle of Chartley in the same county. Her correspondence in cipher from thence with her English agents abroad, intercepted by Walsingham and deciphered by his secretary, gave eager encouragement to the design for a Spanish invasion of England under the prince of Parma,—an enterprise in which she would do her utmost to make her son take part, and in case of his refusal would induce the Catholic nobles of Scotland to betray him into the hands of Philip, from whose tutelage he should be released only on her demand, or if after her death he should wish to return, nor then unless he had become a Catholic. But even these patriotic and maternal schemes to consign her child and reconsign the kingdom to the keeping of the Inquisition, incarnate in the widower of Mary Tudor, were superseded by the attraction of a conspiracy against the throne and life of Elizabeth. Anthony Babington, in his boyhood a ward of Shrewsbury, resident in the household at Sheffield Castle, and thus subjected to the charm before which so many victims had already fallen, was now induced to undertake the deliverance of the queen of Scots by the murder of the queen of England. It is maintained by those admirers of Mary who assume her to have been an almost absolute imbecile, gifted with the power of imposing herself on the world as a woman of unsurpassed ability, that, while cognizant of the plot for her deliverance by English rebels and an invading army of foreign auxiliaries, she might have been innocently unconscious that this conspiracy involved the simultaneous assassination of Elizabeth. In the conduct and detection

of her correspondence with Babington, traitor was played off against traitor, and spies were utilized against assassins, with as little scruple as could be required or expected in the diplomacy of the time. As in the case of the casket letters, it is alleged that forgery was employed to interpolate sufficient evidence of Mary's complicity in a design of which it is thought credible that she was kept in ignorance by the traitors and murderers who had enrolled themselves in her service,—that one who pensioned the actual murderer of Murray and a would-be murderer of Elizabeth was incapable of approving what her keen and practised intelligence was too blunt and torpid to anticipate as inevitable and inseparable from the general design. In August the conspirators were netted, and Mary was arrested at the gate of Tixall Park, whither Paulet had taken her under pretence of a hunting party. At Tixall she was detained till her papers at Chartley had undergone thorough research. That she was at length taken in her own toils even such a dullard as her admirers depict her could not have failed to understand; that she was no such dastard as to desire or deserve such defenders the whole brief course of her remaining life bore consistent and irrefragable witness. Her first thought on her return to Chartley was one of loyal gratitude and womanly sympathy. She cheered the wife of her English secretary, now under arrest, with promises to answer for her husband to all accusations brought against him, took her new-born child from the mother's arms, and in default of clergy baptized it, to Paulet's Puritanic horror, with her own hands by her own name. The next or the twin-born impulse of her indomitable nature was, as usual in all times of danger, one of passionate and high-spirited defiance, on discovering the seizure of her papers. A fortnight afterwards her keys and her money were confiscated, while she, bedridden and unable to move her hand, could only ply the terrible weapon of her bitter and fiery tongue. Her secretaries were examined in London, and one of them gave evidence that she had first heard of the conspiracy by letter from Babington, of whose design against the life of Elizabeth she thought it best to take no notice in her reply, though she did not hold herself bound to reveal it. On the 25th of September she was removed to the strong castle of Fotheringay in Northamptonshire. On the 6th of October she was desired by letter from Elizabeth to answer the charges brought against her before certain of the chief English nobles appointed to sit in commission on the cause. In spite of her first refusal to submit, she was induced by the arguments of the vice-chamberlain, Sir Christopher Hatton, to appear before this tribunal on condition that her protest should be registered against the legality of its jurisdiction over a sovereign, the next heir of the English crown.

On the 14th and 15th of October 1586 the trial was held in the hall of Fotheringay Castle. Alone, "without one counsellor on her side among so many," Mary conducted the whole of her own defence with courage incomparable and unsurpassable ability. Pathos and indignation, subtlety and simplicity, personal appeal and political reasoning, were the alternate weapons with which she fought against all odds of evidence or inference, and disputed step by step every inch of debatable ground. She repeatedly insisted on the production of proof in her own handwriting as to her complicity with the project of the assassins who had expiated their crime on the 20th and 21st of the month preceding. When the charge was shifted to the question of her intrigues with Spain, she took her stand resolutely on her right to convey whatever right she possessed, though now no kingdom was left her for disposal, to whomsoever she might choose. One single slip she made in the whole course of her defence: but none could have been more unluckily characteristic and significant. When Burghley brought against her the unanswerable charge of having at that moment in her service, and in receipt of an annual pension, the instigator of a previous attempt on the life of Elizabeth, she had the unwary audacity to cite in her justification the pensions allowed by Elizabeth to her adversaries in Scotland, and especially to her son. It is remarkable that just two months later, in a conversation with her keepers, she again made use of the same extraordinary argument in reply to the same inevitable imputation, and would not be brought to admit that the two cases were other than parallel. But except for this single instance of oversight or perversity her defence was throughout a masterpiece of indomitable ingenuity, of delicate and steadfast courage, of womanly dignity and genius. Finally she demanded, as she had demanded before, a trial either before the estates of the realm lawfully assembled, or else before the queen in council. So closed the second day of the trial; and before the next day's work could begin a note of two or three lines hastily written at midnight informed the commissioners that Elizabeth had suddenly determined to adjourn the expected judgment and transfer the place of it to the star-chamber. Here, on the 25th of October, the commissioners again met; and one of them alone, Lord Zouch, dissented from the verdict by which Mary was found guilty of having, since the 1st of June preceding, compassed and imagined divers matters tending to the destruction of Elizabeth. This verdict was conveyed to her, about three weeks later, by Lord Buckhurst and Robert Beale, clerk of the privy council. At the intimation that her life was an impediment to the security of the received religion, "she seemed with a certain unwonted alacrity to triumph, giving God thanks, and rejoicing in her heart that she was held to be an instrument" for the restoration of her own faith. This note of exultation as in martyrdom was maintained with unflinching courage to the last. She wrote to Elizabeth and the duke of Guise two letters of almost matchless eloquence and pathos, admirable especially for their loyal and grateful remembrance of all her faithful servants. Between the date of these letters and the day of her execution wellnigh three months of suspense elapsed. Elizabeth, fearless almost to a fault in face of physical danger, constant in her confidence even after discovery of her narrow escape from the poisoned bullets of household conspirators, was cowardly even to a crime in face of subtler and more complicated peril. She rejected with resolute dignity the intercession of French envoys for the life of the queen-dowager of France; she allowed the sentence of death to be proclaimed, and welcomed with bonfires and bell-ringing throughout the length of England; she yielded a respite of twelve days to the pleading of the French ambassador, and had a charge trumped up against him of participation in a conspiracy against her life; at length, on the 1st of February 1587, she signed the death-warrant, and then made her secretaries write word to Paulet of her displeasure that in all this time he should not of himself have found out some way to shorten the life of his prisoner, as in duty bound by his oath, and thus relieve her singularly tender conscience from the guilt of bloodshed. Paulet, with loyal and regretful indignation, declined the disgrace proposed to him in a suggestion "to shed blood without law or warrant"; and on the 7th of February the earls of Shrewsbury and Kent arrived at Fotheringay with the commission of the council for execution of the sentence given against his prisoner. Mary received the announcement with majestic tranquillity, expressing in dignified terms her readiness to die, her consciousness that she was a martyr for her religion, and her total ignorance of any conspiracy against the life of

Elizabeth. At night she took a graceful and affectionate leave of her attendants, distributed among them her money and jewels, wrote out in full the various legacies to be conveyed by her will, and charged her apothecary Gorion with her last messages for the king of Spain. In these messages the whole nature of the woman was revealed. Not a single friend, not a single enemy, was forgotten; the slightest service, the slightest wrong, had its place assigned in her faithful and implacable memory for retribution or reward. Forgiveness of injuries was as alien from her fierce and loyal spirit as forgetfulness of benefits; the destruction of England and its liberties by Spanish invasion and conquest was the strongest aspiration of her parting soul. At eight next morning she entered the hall of execution, having taken leave of the weeping envoy from Scotland, to whom she gave a brief message for her son; took her seat on the scaffold, listened with an air of even cheerful unconcern to the reading of her sentence, solemnly declared her innocence of the charge conveyed in it and her consolation in the prospect of ultimate justice, rejected the professional services of Richard Fletcher, dean of Peterborough, lifted up her voice in Latin against his in English prayer, and when he and his fellow-worshippers had fallen duly silent prayed aloud for the prosperity of her own church, for Elizabeth, for her son, and for all the enemies whom she had commended overnight to the notice of the Spanish invader; then, with no less courage than had marked every hour and every action of her life, received the stroke of death from the wavering hand of the headsman.

Mary Stuart was in many respects the creature of her age, of her creed, and of her station; but the noblest and most noteworthy qualities of her nature were independent of rank, opinion, or time. Even the detractors who defend her conduct on the plea that she was a dastard and a dupe are compelled in the same breath to retract this implied reproach, and to admit, with illogical acclamation and incongruous applause, that the world never saw more splendid courage at the service of more brilliant intelligence, that a braver if not "a rarer spirit never did steer humanity." A kinder or more faithful friend, a deadlier or more dangerous enemy, it would be impossible to dread or to desire. Passion alone could shake the double fortress of her impregnable heart and ever active brain. The passion of love, after very sufficient experience, she apparently and naturally outlived; the passion of hatred and revenge was as inextinguishable in her inmost nature as the emotion of loyalty and gratitude. Of repentance it would seem that she knew as little as of fear, having been trained from her infancy in a religion where the Decalogue was supplanted by the Creed. Adept as she was in the most exquisite delicacy of dissimulation, the most salient note of her original disposition was daring rather than subtlety. Beside or behind the voluptuous or intellectual attractions of beauty and culture, she had about her the fresher charm of a fearless and frank simplicity, a genuine and enduring pleasure in small and harmless things no less than in such as were neither. In 1562 she amused herself for some days by living "with her little troop" in the house of a burgess of St Andrews "like a burgess's wife," assuring the English ambassador that he should not find the queen there,—"nor I know not myself where she is become." From Sheffield Lodge, twelve years later, she applied to the archbishop of Glasgow and the cardinal of Guise for some pretty little dogs, to be sent her in baskets very warmly packed,—"for besides reading and working, I take pleasure only in all the little animals that I can get." No lapse of reconciling time, no extent of comparative indulgence, could break her in to resignation, submission, or toleration of even partial restraint. Three months after the massacre of St Bartholomew had caused some additional restrictions to be placed upon her freedom of action, Shrewsbury writes to Burghley that "rather than continue this imprisonment she sticks not to say she will give her body, her son, and country for liberty"; nor did she ever show any excess of regard for any of the three. For her own freedom of will and of way, of passion and of action, she cared much; for her creed she cared something; for her country she cared less than nothing. She would have flung Scotland with England into the hellfire of Spanish Catholicism rather than forego the faintest chance of personal revenge. Her profession of a desire to be instructed in the doctrines of Anglican Protestantism was so transparently a pious fraud as rather to afford confirmation than to arouse suspicion of her fidelity to the teaching of her church. Elizabeth, so shamefully her inferior in personal loyalty, fidelity, and gratitude, was as clearly her superior on the one all-important point of patriotism. The saving salt of Elizabeth's character, with all its wellnigh incredible mixture of heroism and egotism, meanness and magnificence, was simply this, that, overmuch as she loved herself, she did yet love England better. Her best though not her only fine qualities were national and political, the high public virtues of a good public servant; in the private and personal qualities which attract and attach a friend to his friend and a follower to his leader, no man or woman was ever more constant and more eminent than Mary, Queen of Scots. (A. C. S.)

MARYBOROUGH, a town of Queensland, Australia, in the county of March, on the left bank of the Mary river, 25 miles from its mouth, about 180 miles north of Brisbane, in 25° 35′ S. lat. and 152° 43′ E. long. It is the principal shipping port for an extensive district, communicating by steamer and coach with Brisbane and (since 1881) by railway with the Gympie gold-fields, 54 miles to the south. A large shipbuilding yard, saw-mills, distilleries, breweries, and soap-works are among the industrial establishments of the town, and extensive sugar factories exist in the neighbourhood. Besides a handsome courthouse and town-hall, the public buildings comprise a hospital, a school of arts with a considerable library, and immigration barracks. Gas-lighting and water from the Tinana creek were both introduced in 1879. The population of the census district in 1876 was 8608, that of the municipal area about 7000. Maryborough had only about 600 inhabitants in 1860; the municipality dates from 1861, and was reincorporated in 1875.

## MARYLAND.

MARYLAND, one of the central Atlantic States, and one of the original thirteen, lies between the parallels of 37° 53′ and 39° 43′ 26″ W. lat. and the meridians of 75° 4′ and 79° 33′ W. long. from Greenwich. It is bounded on the north by Pennsylvania and Delaware; on the east by Delaware and the Atlantic ocean; on the south and west by the Potomac river and its estuary, which separate it from Virginia and West Virginia. Its width varies from 3 or 4 miles to 120 miles; its extreme length from east to west is 198 miles. The total area of the State is 12,210 square miles, of which 9,860 square miles is land surface, and 2,350 square miles is covered by the waters of the Potomac and other rivers, and of Chesapeake bay. Plate VI

*Topography.*—The eastern shore is mostly level, and in portions swampy, but toward the neck of the peninsula, at the north, more rocky and broken. The western shore is level and sandy as far north as the Great Falls of the Potomac; above that point it rises in terraces, and soon in broken and rugged hills. The country is quite mountainous toward the northwest, in the vicinity of Rockville. The five or six mountain ranges of the Alleghanies, including Blue Ridge and Laurel Ridge, extend across the narrow northwest portion of the State. The

highest mountains are in Garrett county in the extreme western part of the State, but none of them are over 2,500 feet high. Washington county, lying between Tuscarora mountain and South mountain, is a part of the Cumberland valley, and is renowned for its picturesque scenery, and for its rich soil. The Atlantic coast proper has a length of only 33 miles, with no good harbors; but Chesapeake bay, which is the central geographical feature of the State, and extends in a northerly direction almost to the northern boundary of the State, furnishes a coast line of more than 500 miles. At its ocean mouth, the bay is 12 miles wide; its width at the widest point is 40 miles, and its average breadth is 10 miles. It is navigable throughout its whole extent, and has numerous excellent harbors. The principal river is the Potomac, which is navigable for 125 miles to Washington city. The Potomac rises in the mountains of West Virginia, and flows first northeast and then southeast for a distance of about 450 miles. The lower part of the river below Alexandria is, in reality, an estuary, where it widens out to a great breadth. The Patuxent, which is its largest river wholly within the State, is navigable for small craft about 40 miles. The Patapsco, on which the city of Baltimore is situated, is navigable for 22 miles. The other rivers of the State are—on the eastern shore, the Pocomoke, Manokin, Nanticoke, Choptank, St. Michaels, Wye, Chester, Sassafras and Elk; on the western shore, the Wicomico, South, Severn, Bush and Susquehanna. Many of these are rather estuaries than rivers, especially in the lower part of their courses, and are not navigable for any distance above their mouths. The tide rises and falls in all these rivers. Three sounds, known as St. Martin's bay, Sinepuxent bay and Chincoteague bay, lie between the eastern shore and the island reefs that receive the Atlantic surf. There are numerous islands in Chesapeake bay and Pocomoke sound. Tangier sound and Eastern bay are in reality only portions of Chesapeake bay, separated from it by these islands, the largest of which are Assateague, Tangier, Smith's, Holland's, Bloodworth's, and Kent.

*Geology.*—The lower part of the eastern shore as far north as the Choptank river, St. Mary's and Calvert counties on the western shore, and the islands in the bay are wholly alluvial. The northern part of the eastern shore, between the Choptank and the Elk river, and Ann Arundel, Princes George and Charles counties on the western shore, are a Tertiary formation, mainly Pleistocene and Miocene, with some argillaceous clays and slates of earlier date, which are of great value as a fertilizer. A narrow belt of the cretaceous formation runs southwesterly from New Jersey to the Potomac. Beyond this is a wide strip of Eozoic rocks, of which the more important are limestone, gneiss, granite, serpentine, talc-slates and hydrated magnesian silicates. A narrow strip of the new red sandstone runs through the middle of this Eozoic belt, entering the State near the head of the bay, and extending southwest through the eastern part of Frederick county to the Potomac. Westward of the metamorphic rocks is a wide belt of the Silurian formation, containing Potsdam sandstones, Trenton limestones, etc. Following these are the Devonian red shales and sandstones, which, in the extreme northwestern part of the State, are overlaid by the carboniferous formation, containing some of the most important bituminous coal measures in America. Of these, the largest are in the vicinity of George's creek valley, east of Savage mountain. In this valley, which is about 20 miles long, is the "big seam," having a thickness of 14 feet. Copper, chrome iron, hæmatitic iron and other minerals, including manganese, galena and barytes, are found in the belt of Eozoic rocks in the center of the State. Breccia and other marbles and building sandstones and limestones are quarried from these rocks. Bog iron is found on the eastern shore.

In 1880, Maryland produced 2,227,844 tons of bituminous coal, valued at $2,584,455; 57,940 tons of iron ore, valued at $118,050; 672 tons of zinc ore, valued at $7,200, and 30,910 pounds of copper ingots; the total value of all mineral products was $2,869,008.

*Soil and Vegetation.*—In the eastern part of the State the soil is composed of clay and sand, is easily tilled, and with a fair supply of fertilizers yields excellent crops. Peaches and other fruits are successfully cultivated on these lands. It is estimated that Maryland, Delaware and New Jersey furnish nearly nine-tenths of the peach crop of the Atlantic coast. In the central and northern counties of the State the valley soil is very fertile, yielding large crops of tobacco, Indian corn and wheat. Among the forest trees, the deciduous oaks, maple, hickory, walnut, chestnut, ash, birch, the pine and spruce are especially abundant in the mountainous districts. The beech, poplar, sycamore, sassafras, red maple, cedar, gum, cypress, elm, dogwood, magnolia, juniper and holly trees are found in the lowlands. In all, there are about one hundred species of trees in the State.

*Climate.*—The climate of Maryland is equable and generally healthful, removed both from the protracted heat of the south and from the extreme cold of the north. Along the marshy lands, bordering the lower Potomac and the bay, miasmatic influences are prevalent, and fevers of a kindred nature occur. The average mean temperature in the western part of the State is 50°, in the middle 54°, and in the southern 56°. At Baltimore the average mean temperature of the year is 54° 64′; of spring, 48.2°; of summer, 76.3°; of autumn, 47.2°; of winter, 33.6°. The total rainfall for the year is 48.11 inches. The mean annual barometer is 30.057 inches. In 1880 the death rate in the state was 1.81 per cent.

*Fisheries.*—The oyster fishery is the most important of the Maryland fisheries. In 1880, the number of persons employed in the fisheries was 26,008; the capital invested was $6,342,443; the value of products was $5,221,715. The number of vessels was 1,450, with a tonnage of 43,500, and a value of $1,750,000. The number of boats was 2,825, with a value of $186,448. The value of the products of the general fisheries was $479,388; of the menhaden fishery, $11,851; of the oyster fishery, $4,730,476.

*Manufactures.*—In 1880 there were 6,787 mechanical and manufacturing establishments in Maryland, employing a capital of $58,742,384, the total number of operatives was 74,945, of whom 46,698 were males above 16 years of age; 21,700 females above 15 years and 6,547 were children and youths. The total amount paid in wages during the year was $18,904,965; the value of materials was $66,937,846, and the value of products $106,780,563.

*Railroads.*—The railroad system of Maryland with the exception of a few local roads, is so vitally connected with that of other States, and is so little under the control of the State, that it can scarcely be considered by itself. The most important road is the Baltimore & Ohio, which, including its branches, has more than 300 miles of track in the State. In 1886,* the total length of line of railroads in the State was 1,246 miles; the length of line operated was 1,202 miles. The capital stock was $46,313,224; the bonded debt, $44,019,200; the unfunded debt, $2,617,520; the cost of railroads and equipments, $93,522,155. The gross earnings from all sources were $13,078,692; the net earnings, $5,113,596.

*Commerce.*—The principal imports are coffee, iron and salt; the principal exports, tobacco, grain and petroleum. The value of the foreign imports in 1880 was $18,643,245; of the foreign exports, $74,398,971. There are three ports of entry, of which the port of Baltimore is the most important. In 1880, the number of foreign vessels arriving was 1,508; of foreign clearances was 1,633; the number of vessels registered in the State was 1,788.

*Agriculture.*—The following table gives the farm statistics of Maryland for the census years 1850-80:

| Year. | Total Number of Farmers. | Total Land in Farms. | Improved Land in Farms. | Acreage Size of Farms. | Value of Farms. | Value of Farming Implements and Machinery. |
|---|---|---|---|---|---|---|
| | | Acres. | Acres. | Acres. | | |
| 1850 | 21,860 | 4,634,350 | 2,797,905 | 212 | $ 87,178,545 | $2,463,443 |
| 1860 | 25,494 | 4,835,571 | 3,002,267 | 190 | 145,973,677 | 4,010,529 |
| 1870 | 27,000 | 4,512,579 | 2,914,007 | 167 | 170,369,684 | 5,268,676 |
| 1880 | 40,517 | 5,119,831 | 3,342,700 | 126 | 165,503,341 | 5,788,197 |

*From Poor's Manual of the Railroads of the United States for 1887.

Following is a table giving general statistics of agriculture for the State of Maryland in the census years 1850–80:

| Year. | Irish Potatoes, Bushels. | Sweet Potatoes, Bushels. | Value of Live Stock. | Horses, Number. | Milch Cows, Number. | Sheep, Number. | Butter, Pounds. | Cheese, Pounds. |
|---|---|---|---|---|---|---|---|---|
| 1850 | 764,939 | 208,998 | $ 7,997,634 | 75,684 | 86,856 | 177,902 | 3,806,160 | 8,975 |
| 1860 | 1,264,459 | 236,740 | 14,667,853 | 89,406 | 99,483 | 155,765 | 5,265,295 | 8,542 |
| 1870 | 1,632,205 | 218,706 | 16,433,698 | 89,096 | 94,794 | 129,637 | 5,014,729 | 6,732 |
| 1880 | 1,497,017 | 339,590 | 15,865,728 | 117,796 | 129,907 | 171,184 | 7,485,871 | 17,416 |

| Year. | Barley, Bushels. | Buckwheat, Bushels. | Indian Corn, Bushels. | Oats, Bushels. | Rye, Bushels. | Wheat, Bushels. | Wool, Pounds. | Hay, Tons. | Tobacco, Pounds. |
|---|---|---|---|---|---|---|---|---|---|
| 1850 | 745 | 103,671 | 10,749,858 | 2,949,151 | 226,014 | 4,494,690 | 477,498 | 157,956 | 21,407,497 |
| 1860 | 17,350 | 213,338 | 13,444,922 | 3,950,398 | 518,901 | 6,103,490 | 491,511 | 191,744 | 38,410,965 |
| 1870 | 11,315 | 77,867 | 11,701,817 | 3,221,643 | 307,089 | 5,774,503 | 495,913 | 223,119 | 15,765,339 |
| 1880 | 6,097 | 136,667 | 15,968,533 | 1,794,872 | 288,067 | 8,004,864 | 850,064 | 264,468 | 26,092,147 |

The staple crops of the State are tobacco, Indian corn and wheat. Maryland ranks seventh among the States in the production of tobacco.

*Finances.*—In 1880, the net* State debt was $7,627,668; the net county debt, $1,377,325; the municipal debt, including township and school district debt, $1,891,013; the total debt, $10,896,006. The estimated true valuation of property was $869,000,000. On October 1, 1887, the State debt (funded) was $10,960, 535. But as an offset to this, the State held $4,518,799 in interest-paying securities of corporations, besides $27,723,287 in unproductive securities. The amount raised by taxation in 1886 was $970,860. The amount of taxable property as assessed was $485,839,772, including both real and personal. The State tax on $100 was 18¾ cents. During the year 1885–86 $1,298,997 was paid in salaries to teachers, and the total expenses of public schools in the State were $1,832,383.

*Education.*—In 1880, the whole number of public schools was 2,551, of which 109 were reported as high schools, or as having high school departments, and 436 were separate schools for colored children. The number of school buildings was 1,934. The total value of school property was $2,083,013. The total receipts were $1,452,557, of which $1,343,707 was received from State, county, city and other public funds. The total expenditures were $1,395,284, of which $1,117,145 were paid for teachers' salaries. The total number of teachers was 3,038, of whom 387 were colored. The whole number of pupils who attended school during the year was 149,981, of whom 26,533 were colored. The total average daily attendance of pupils was 85,449. There are ten colleges in the State. They are: Frederick college, at Frederick, established in 1797; Loyola college, at Baltimore, established in 1853; Mt. St. Clement's college, at Ilchester, established in 1853; Mt. St. Mary's college, at Emmittsburg, established in 1808; Rock Hill college, at Ellicott City, established in 1867; St. Charles' college, near Ellicott City, established in 1848; St. John's college, at Annapolis, established in 1789; Washington college, at Chestertown, established in 1783; Western Maryland college, at Westminster, established in 1867, and Baltimore Female College, at Baltimore, established in 1849. Among the schools of a special character, Johns Hopkins University stands pre-eminent. It is situated at Baltimore. It was opened in 1876, with an endowment of more than three million dollars. The other schools of a special character are the Peabody Institute, at Baltimore, with an endowment of $1,171,466, and the McDonogh School and Institute, at Owing's Mills. There are in the State three normal schools, five schools of medicine, and one school of science. The United States Military Academy, at Annapolis, was established in 1850.

*General Social Statistics.*—In 1880 the whole total number of insane was 1,857, of whom 865 were male and 992 female; the total number of idiots was 1,319, of whom 806 were male and 513 female; the total number of blind was 946, of whom 477 were male and 469 female; the total number of deaf-mutes was 671, of whom 366 were male and 305 female; the total number of paupers was 1,334, of whom 1,187 were inmates of almshouses. Of these 664 were male and 523 female; the total number of prisoners was 1,262, of whom 1,089 were male and 173 female. Maryland has one State and four private insane asylums; two State blind institutions, one for white and the other for colored inmates; one public and one private institution for deaf-mutes; one State penitentiary, and one State and three private reformatories, and one State house of correction. In 1880 there were 143 periodicals published in the State, of which 105 were devoted to news, politics and family reading, and 10 were religious. The principal religious denominations are the Methodists, Episcopalians, Roman Catholics, Presbyterians, Baptists and Lutherans.

*Administration.*—The executive power of the State is vested in the governor, who is chosen by the electors for a term of four years. He holds the pardoning power, and any bills that he may veto can only be passed over the veto by a three-fifths vote of all the members of each house. He nominates, and with the advice and consent of the senate, appoints the secretary of State, commissioner of the land office, the adjutant-general of the militia, the State librarian, and the coroners and notaries public. He also appoints an assistant secretary of State, the State board of health, two commissioners of fisheries, the auctioneers of Baltimore city, and other subordinate officers. He receives a salary of $4,500 per annum. The comptroller of the treasury is elected by the voters for two years; the treasurer is selected by the two houses of the legislature for the same term. The attorney-general and superintendent of labor and agriculture are chosen in the same manner, and for the same term of office as the governor. The governor appoints the State board of education, with the advice and consent of the senate, and the principal of the normal school is *ex officio* a member of the board, and usually its superintendent of public instruction. The legislature consists of a senate of 26 members, elected for four years, and a house of delegates of 91 members, elected for two years. The legislature called the general assembly, meets biennially, and by the constitution its sessions are limited to ninety days. The judicial power of the State is vested in the court of appeals, circuit courts of the counties, several courts of Baltimore city, orphans' courts, and justices of the peace. These judges must all be citizens of Maryland, must be qualified voters, and have resided in the State not less than five years, and in the district not less than six months. They are elected by the people of their respective districts for a term of fifteen years, unless they sooner attain the age of seventy years, when their office expires. The court of appeals is composed of the chief judges of the first seven judicial circuits of the State, and a judge from Baltimore city, elected specially thereto. The chief justice is appointed by the governor from among the judges of the court, with the advice and consent of the senate. There are eight judicial circuits, for the courts of each of which there is to be one chief and two associate justices, except in Baltimore city, where the number of associate judges is necessarily increased. The orphans' courts are presided over by three judges in each county and in Baltimore city, who are elected for four years. Their powers are substantially the same with those of the judges of the probate or surrogates in other States. The judges of the peace in each county are appointed by the governor for two years, with the advice and consent of the senate. The State is entitled to six representatives in congress.

*After deducting sinking funds.

*Population.*—The following table gives the population at each census, 1790–1890:

| Census Year. | White. | Free Colored. | Slaves. | Total. | Male. | Female. | Native. | Foreign. |
|---|---|---|---|---|---|---|---|---|
| 1790 | 208,649 | 8,043 | 103,036 | 319,728 | *107,254 | *101,395 | ..... | ..... |
| 1800 | 216,326 | 19,587 | 105,635 | 341,548 | *110,650 | *105,676 | ..... | ..... |
| 1810 | 235,117 | 33,927 | 111,502 | 380,546 | *130,220 | *114,897 | ..... | ..... |
| 1820 | 260,223 | 39,730 | 107,397 | 407,350 | 206,862 | 200,488 | ..... | ..... |
| 1830 | 291,108 | 52,938 | 102,994 | 447,040 | 225,688 | 221,352 | ..... | ..... |
| 1840 | 318,204 | 62,078 | 89,737 | 470,019 | 234,059 | 235,960 | ..... | ..... |
| 1850 | 417,943 | 74,723 | 90,368 | 583,034 | 297,471 | 285,698 | 531,476 | 51,209 |
| 1860 | 515,918 | 83,942 | 87,189 | 687,049 | 340,898 | 346,151 | 609,520 | 77,529 |
| 1870 | 605,497 | 175,391 | ..... | 780,894 | 384,984 | 395,910 | 697,482 | 83,412 |
| 1880 | 724,693 | 210,230 | ..... | 934,943 | 462,187 | 472,756 | 852,137 | 82,806 |
| 1890 | . | . | ..... | 1,042,390 | ..... | ..... | ..... | ..... |

* Whites only enumerated.

In 1890 the following cities and towns had a population exceeding 4,000:

| | |
|---|---|
| Baltimore | 434,439 |
| Cumberland | 12,729 |
| Hagerstown | 10,118 |
| Frederick | 8,193 |
| Annapolis | 7,604 |

Annapolis, the capital of the State, is the seat of the naval academy of the United States.

The State is divided into 24 counties, and the corporation of the city of Baltimore. The counties, with population, in 1890, are Alleghany (41,571); Anne Arundel (34,094); Baltimore (72,909); Baltimore city (434,439); Calvert (9,860); Caroline (13,766); Carroll (32,376); Cecil (25,851); Charles (15,191); Dorchester (24,843); Frederick (49,512); Garrett (14,213); Harford (28,042); Howard (16,140); Kent (17,605); Montgomery (27,759); Prince George (26,451); Queen Anne (18,461); Saint Mary's (15,819); Somerset (24,155); Talbot (19,065); Washington (39,561); Wicomico (19,016); Worcester (19,539).

*History.*—William Clayborne, of Virginia, made the first white settlement within the present limits of Maryland in 1631. In 1632, Cecilius Calvert, second Lord Baltimore, obtained a charter from Charles I. with greater power than had ever before been bestowed on any colonial proprietor. In 1634 Cecilius sent his brother, Leonard Calvert, as governor of the colony with 200 emigrants. They landed at St. Mary's; named the colony Maryland in honor of the queen, Henrietta Maria, and commenced a permanent settlement there. Clayborne, who was disposed to make serious trouble for the new colonists, was indicted by the legislature for murders, piracy and sedition, and to escape punishment he fled to England. Lord Baltimore, though himself a Roman Catholic, welcomed men of all religions and of none, to his colony. Consequently the colony had a rapid growth. In 1642 an Indian war commenced which was attributed by the colonists to intrigues of Clayborne or his followers. In 1645 Clayborne led a rebellion from Kent Island. Although formidable, it was suppressed in August of the following year. For the next twelve years the colony was in constant turmoil. The Puritans in the vicinity of Providence (now Annapolis) allied themselves with Clayborne. They increased rapidly in numbers, and in 1652 commissioners from England, with whom Clayborne was associated, visited Maryland, deposed the acting governor, and fully established the authority of the commonwealth. Lord Baltimore, after a determined effort, succeeded in regaining possession of the province, and reinstated Governor Stone, but Clayborne interfered and overturned the government, placing it in the hands of commissioners. A civil contest ensued in which the proprietary party was defeated. In 1658 Lord Baltimore regained his proprietary rights, and his brother, Phillip Calvert, was appointed governer. The colony increased rapidly, containing 12,000 inhabitants in 1660, and 20,000 in 1671. In 1689 King William assumed the government of the province. In 1714 Benedict Charles Calvert, fourth Lord Baltimore, succeeded his father's proprietary rights, and having been educated as a Protestant, regained his authority the following year. From that time forward the colony grew rapidly. Baltimore was founded in 1729. In the two French wars Maryland bore an honorable part. From 1754 to 1758 Maryland was kept in constant fear of Indian raids. Maryland was governed by the Baltimores until the revolution of 1776, into which its people entered with spirit. The "Maryland line" was noted for its daring, taking a prominent part in most of the decisive battles of the war. It was to the congress assembled at Annapolis that General Washington resigned his commission. Maryland ratified the constitution of the United States April 28, 1788. The State sustained severe losses in the war of 1812. In the late civil war Maryland, although a slave-holding State, was prevented from leaving the Union by the prompt and decisive action of the federal government. Since the war the State has been pushing forward its activities in every direction, and has been earnestly striving to become more firmly bound to the great West. The present constitution was adopted in 1867. E. H. F.

MARYPORT, a market and seaport town of Cumberland, England, is situated on the Irish Sea, 29 miles southwest from Carlisle. It is irregularly built, partly on a cliff and partly on the sea-shore. The streets are spacious, but there are no public buildings of importance. The town until 1750 consisted of a few huts called Ellenfoot, when a harbour was constructed by Humphrey Senhouse, which gave a great impulse to its prosperity. The principal exports are coal to Ireland and pig-iron to the Continent, the principal imports timber and general merchandise. Shipbuilding is carried on to a small extent. In 1881 the number of vessels that entered from foreign and colonial ports was 72, of 35,241 tons burden; the number that cleared 120, of 60,840 tons burden. The coasting trade is much more important, the number of vessels that entered being 1805, of 215,332 tons burden, and the number that cleared 1753, of 187,290 tons. There are rope and sailcloth works, iron foundries, and saw-mills, also brewing and tanning. The population of the urban sanitary district in 1871 was 7443, and in 1881 it was 8177. There was a Roman camp in the neighbourhood of Maryport, and the district is rich in Roman antiquities.

MASACCIO (1402–1429). Tommaso Guidi, son of a notary, Ser Giovanni di Simone Guidi, of the family of the Scheggia, who had property in Castel S. Giovanni di Val d'Arno, was born in 1402, and acquired the nickname of Masaccio, which may be translated "Lubberly Tom," in consequence of his slovenly dressing and deportment. He loved to be alone and at home, neglected "appearances" of all sorts, and was constantly wool-gathering when not intently occupied with his work; he had no vices, however, and would always do a good turn to an acquaintance. From childhood he showed a great inclination for the arts of design, and he is said to have studied under his contemporary Masolino da Panicale. In 1421, or perhaps 1423, he was enrolled in the guild of the speziali (druggists) in Florence, in 1424 in the guild of painters. His first attempts in painting were made in Florence, and then in Pisa. Next he went to Rome, still no doubt very young; although the statement that he returned from Rome to Florence, in 1420, when only eighteen or nineteen, seems incredible, considering what were the works which he undertook in the papal city. These included a series of frescos still extant in a chapel of the church of S. Clemente, a Crucifixion, and scenes from the life of St Catherine and of St Clement, or perhaps some other saint. Though much inferior to his later productions, these paintings are, for naturalism and propriety of representation, in advance of their time. Some critics, however, consider that the design only, if even that, was furnished by Masaccio, and the execution left to an inferior hand; this appears highly improbable, as Masaccio, at his early age, can scarcely have held the position of a master laying out work for subordinates; indeed Vasari says that Lubberly Tom was held in small esteem at all times of his brief life. In the crucifixion subject the group of the Maries is remarkable; the picture most generally admired is that of

Catherine, in the presence of Maxentius, arguing against and converting eight learned doctors. After returning to Florence, Masaccio was chiefly occupied in painting in the church of the Carmine, and especially in that "Brancacci chapel" which he has rendered famous almost beyond rivalry in the annals of painting.

The chapel had been built early in the 15th century by Felice Michele di Piuvichese Brancacci, a noble Florentine. Masaccio's work in it began probably in 1423, and continued at intervals until he finally quitted Florence in 1428. There is a whole library-shelf of discussion as to what particular things were done by Masaccio and what by Masolino, and long afterwards by Filippino Lippi, in the Brancacci chapel, and also as to certain other paintings by Masaccio in the Carmine. He began with a trial piece, a majestic figure of St Paul, not in the chapel; this has perished. A monochrome of the Procession for the Consecration of the Chapel, regarded as a wonderful example, for that early period, of perspective and of grouping, has also disappeared, though there is some suspicion that it might yet, with due pains and research, be recovered; it contained portraits of Brunelleschi, Donatello, and many others. In the cloister of the Carmine was discovered in recent years a portion of a fresco by Masaccio representing a procession; but this, being in colours and not in monochrome, does not appear to be the Brancacci procession. As regards the works in the Brancacci chapel itself, the prevalent opinion now is that Masolino, who used to be credited with a considerable portion of them, did either nothing, or at the utmost the solitary compartment which represents St Peter restoring Tabitha to life, and the same saint healing a cripple. The share which Filippino Lippi bore in the work admits of little doubt; to him are due various items on which the fame of Masaccio used principally to be based—as for instance the figure of St Paul addressing Peter in prison, which Raphael partly appropriated; and hence it may be observed that an eloquent and often-quoted outpouring of Sir Joshua Reynolds in praise of Masaccio ought in great part to be transferred to Filippino. What Masaccio really painted in the chapel appears with tolerable certainty to be as follows, and is ample enough to sustain the high reputation he has always enjoyed:—(1) The Temptation of Adam and Eve; (2) Peter and the Tribute-Money; (3) The Expulsion from Eden; (4) Peter Preaching; (5) Peter Baptizing; (6) Peter Almsgiving; (7) Peter and John Curing the Sick; (8) Peter Restoring to Life the Son of King Theophilus of Antioch was begun by Masaccio, including the separate incident of Peter Enthroned, but a large proportion is by Filippino; (9) the double subject already allotted to Masolino may perhaps be by Masaccio, and in that case it must have been one of the first in order of execution. A few words may be given to these pictures individually. (1) The Temptation shows a degree of appreciation of nude form, corresponding to the feeling of the antique, such as was at that date unexampled in painting. (2) The Tribute-Money, a full, harmonious, and expressive composition, contains a head reputed to be the portrait of Masaccio himself,—one of the apostles, with full locks, a solid resolute countenance, and a pointed beard. (3) The Expulsion was so much admired by Raphael that, with comparatively slight modifications, he adopted it as his own in one of the subjects of the Logge of the Vatican. (5) Peter Baptizing contains some nude figures of strong naturalistic design; that of the young man, prepared for the baptismal ceremony, who stands half-shivering in the raw air, has always been a popular favourite, and an object of artistic study. (8) The restoration of the young man to life has been open to much discussion as to what precise subject was in view, but the most probable opinion is that the legend of King Theophilus was intended.

In 1427 Masaccio was living in Florence with his mother, then for the second time a widow, and with his younger brother Giovanni, a painter of no distinction; he possessed nothing but debts. In 1428 he was working, as we have seen, in the Brancacci chapel. Before the end of that year he disappeared from Florence, going, as it would appear, to Rome, to evade the importunities of creditors. Immediately afterwards, in 1429, when his age was twenty-seven, he was reported dead. Poisoning by jealous rivals in art was rumoured, but of this nothing is known. The statement that several years afterwards, in 1443, he was buried in the Florentine church of the Carmine, without any monument, seems to be improbable, and to depend upon a confused account of the dates, which have now, after long causing much bewilderment, been satisfactorily cleared up from extant documents.

It has been said that Masaccio introduced into painting the plastic boldness of Donatello, and carried out the linear perspective of Paolo Uccello and Brunelleschi (who had given him practical instruction), and he was also the first painter who made some considerable advance in atmospheric perspective. He was the first to make the architectural framework of his pictures correspond in a reasonable way to the proportions of the figures. In the Brancacci chapel he painted with extraordinary swiftness. The contours of the feet and articulations in his pictures are imperfect; and his most prominent device for giving roundness to the figures (a point in which he made a great advance upon his predecessors) was a somewhat mannered way of putting the high lights upon the edges. His draperies were broad and easy, and his landscape details natural, and superior to his age. In fact, he led the way in representing the objects of nature correctly, with action, liveliness, and relief. Soon after his death, his work was recognized at its right value, and led to notable advances; and all the greatest artists of Italy, through studying the Brancacci chapel, became his champions and disciples.

Of the works attributed to Masaccio in public or private galleries hardly any are authentic. The one in the Florentine Academy, the Virgin and Child in the Lap of St Anna, is an exception. The so-called portrait of Masaccio in the Uffizi Gallery is more probably Filippino Lippi; and Filippino, or Botticelli, may be the real author of the head, termed a Masaccio, in the London National Gallery.

MASANIELLO (an abbreviation of TOMMASO ANIELLO or ANELLO) was the leader of the Neapolitan revolt in July 1647. For many years the Spanish Government, in straits for money, had exacted large sums from the Two Sicilies, although the privileges granted by Ferdinand and Charles V. had exempted them both from taxes on the necessaries of life and from all external payments whatever. Now, however, under Philip III. and Philip IV., the exactions, heavy in themselves, were made more oppressive by being farmed out to contractors, while the sums raised were usually conveyed to Spain and spent on purposes often having no connexion with Naples. Meantime the industrial classes were scourged by the excesses of the nobility and the lawlessness of banditti. At length, at the end of 1646, the duke of Arcos demanded a million ducats in gold; and it was resolved after much opposition to raise it from fruit, one of the most important articles of food to a southern people. Petitions delayed but did not remove the tax; on June 6 a toll-house was actually blown up, but the viceroy did not give way. The discontent was fomented by Genovino, who had been chosen "elect of the people" (that is, of the district of the city where the common people had the right of voting) in 1619 by the duke of Osuna's influence, and had been employed by him as an agitator. After the duke's recall he had been long in prison, and then returned to Naples and became a priest. He selected for his purpose Masaniello, a fisherman of Naples, then twenty-seven years old, well built, intelligent, and very popular in the city. He was so poor, we are told, that he was usually obliged to content himself with selling paper to wrap up the fish that others sold. He had special cause too for hatred to the taxes: his wife had tried to smuggle a bag of flour into the city as an infant; she had been imprisoned, and his scanty possessions had barely sufficed to pay her fine. The temporary success of a rising at Palermo had stirred the people to a sense of their power, and very little was wanted to produce an explosion. On July 16, the feast of S. Maria del Carmine, it was customary to make a sort of castle which was defended by one body of youths armed with sticks and stormed by another. Masaniello had been chosen captain of one of these parties, and got together four hundred young men, with whom he had already raised the cry of "Down with the taxes" when the crisis was precipitated by a quarrel. On Sunday the 7th a dispute arose in the market (on which Masaniello's house looked) whether the gardeners or the buyers of their

fruit should pay the tax. Finally the owner of the fruit (said to have been a kinsman of Masaniello) upset his basket, saying he would sooner let the people have it for nothing than pay the tax. Masaniello came up; the tax collectors were pelted with fruit and then with stones, and the toll-house was burnt with cries of—"The king of Spain and plenty; down with misgovernment and taxes." The viceroy attempted without effect to quiet the people by promises; his carriage was surrounded, and he escaped with difficulty to St Elmo. Meanwhile the populace broke open the prisons, and released all charged with offences against the customs. In the evening, by advice of Genovino, a meeting elected officers, and decided on their demands. Masaniello was chosen captain, with one Perrone, who had been in the service of Maddaloni, and at another time a captain of banditti, as his lieutenant. Next day the people went in search of arms; many houses of persons who had made themselves obnoxious to the people, and especially of tax farmers, were sacked, and their contents burnt; but most of the historians of the time state that there were few attempts to appropriate anything, and those few were immediately punished. The duke of Maddaloni, a man of lawless life, but a decided opponent of the viceroy, was selected as a likely intermediary with the people. The latter demanded the original charter granted by Charles V., which was said to have wrongfully come into the viceroy's own hands, the removal of all taxes imposed since Charles V.'s death, and that the elect of the people should have as many votes as the representatives of the nobles. All was granted; but the viceroy made entrenchments to guard the approaches to the castle. Next day the sacking of tax farmers' houses went on. The viceroy attempted to cheat the people by sending documents simply drawn up by himself; and then their rage burst out. Maddaloni was seized and given into custody, but escaped in the night by Perrone's connivance. The people were summoned to arms. The cardinal archbishop Filomarino, who did his best to mediate between the parties all through, came to them from the viceroy, and it was arranged that he should bring them the document. The seizure of arms went on, and Masaniello marching out of the city disarmed and took prisoners four hundred soldiers, while another body of people did the same with six hundred German mercenaries. On Wednesday Perrone made his appearance at the head of three hundred bandits partly mounted, and fired upon Masaniello, but without injuring him. The people rushed upon them, and they were killed almost without exception. Some confessed to having been instigated by Maddaloni, and a price was set upon his head. His brother Giuseppe Caraffa was found in a monastery and killed, and his head and foot were set upon pikes. A new elect of the people was chosen, Arpaia, who had been a partisan of Genovino's in the duke of Osuna's time, and had been condemned to the galleys. On Thursday Maddaloni's house was plundered and his property placed in a heap in the market under guard. The castle being short of provisions, Masaniello sent some as a present to the viceroy. The Neapolitan galleys, under Gianettino Doria, arrived the same day, and Masaniello refused permission to land or to come nearer than a mile to the shore, but sent provisions on board. In fact he was now undisputed master of the city, not only organizing the military force in it with surprising ability, but dispensing strict though severe justice. Often he sat inside his little house on the market, sword or loaded gun in hand, while petitions and complaints were handed to him on the end of a pike through the window; yet he still went barefoot, dressed as a simple fisherman. The people having assembled consulted together on the terms of agreement; it was settled by the advice of Genovino that Masaniello should show the articles agreed on to the duke at the palace (he would not risk himself in the castle), and that the viceroy should afterwards swear to them in the cathedral. Towards evening the procession set out, Masaniello in a dress of cloth of silver pressed upon him by the archbishop. An immense concourse of armed men, estimated at one hundred and forty thousand, lined the way or accompanied him. Before them went a trumpet proclaiming *Viva il rè di Spagna ed il fedelissimo popolo di Napoli.* Before entering the palace he exhibited the charter brought by the archbishop, and charged them not to lay down their arms till they had received the confirmation of their rights from the king of Spain. "If I do not return in an hour," he added, "wreck the city." He was received by the viceroy as an equal. All the conditions were agreed to, the chief being—that the elect of the people should have as many votes as the nobles; that all taxes should be removed except those already existing in Charles V.'s time; that the viceroy should get the articles ratified by the king within three months; that no punishment should be inflicted on those who had taken part in the rising; and that the people should keep their arms till the ratification. On the Friday Masaniello dismissed most of his followers to their work, keeping a patrol of four men and a corporal in each street. Next day the ceremony in the cathedral took place; the duke of Canjano read the articles, Masaniello meanwhile correcting and explaining, and the viceroy solemnly swore to observe them. Then Masaniello tore off his rich dress; it was time, he said, to return to his fish. And indeed from this time began his ruin. For a week the care of a city, with hundreds of thousands of inhabitants, had rested upon him; he had been general, judge, legislator, and during the whole time he had hardly slept or eaten, the latter through dread of poison; no wonder if the fisherman's brain reeled under all this. His justice had been severe, but hitherto it had struck men who deserved punishment, the oppressor, the robber, the hired cut-throat; henceforth every one who ventured to contradict him risked his life, and the only man who could persuade him to mercy was the good archbishop. Five hundred in all, it is said, were put to death by his order; though it is probable that they were few compared to the lives taken a short time afterwards by the viceroy in defiance of his plighted word. Next day in fact the duke set to work; Genovino was made president of the chamber in order to detach him from Masaniello, for which he was the more ready as Masaniello was no longer the tool he wanted. Genovino had already prevented the demand for the surrender of St Elmo, which could easily have been enforced, as the fort was not provisioned. Carlo and Salvatore Cataneo with two others offered to the viceroy to murder Masaniello, and he welcomed their services. On Sunday Masaniello gave orders for laying down arms and submitting to the viceroy, which were obeyed in some quarters of the city before they could be recalled. He tried in vain to get the viceroy to accompany him to Posilippo, where he drank deeply, and in reckless extravagance threw gold into the water to be dived for. Next day his violence continued; he struck his followers in the street, and condemned several of his officers to death for not immediately executing his orders. He cut out the head from a picture of Maddaloni and set it on a pike. Vitale his secretary, sent on a message to the viceroy, talked of his intention to raise a million ducats for the king by means of forced gifts from the rich; Vitale was detained in the castle on some pretext, and on leaving next morning was killed by the people of the quarter, who had returned to their allegiance. On Tuesday the 16th, the feast of S. Maria del Carmine, Masaniello went up into the pulpit, and in a wild harangue recapitulated his services. He knew, he

said, his death was near at hand; then tearing open his dress he showed his body emaciated by fatigue and want of food. After some more wild talk he was disarmed and confined in a cell in the monastery. There the quiet seems to have restored him; but his assassins soon broke in; he turned to meet them; five shots were at once fired, and he fell dead. His head was cut off and carried through the streets, while his body was dragged about for a while and then buried outside the city. Next day some boys went and dug up the body, washed it, and took the head from the guard in charge of it. The Neapolitans forgot the excesses of the last few days, and only remembered the leader who had won them their great victory. People plucked out his hairs and preserved them as relics, some even prayed to him as a saint. All the priests of the city officiated at the funeral, and even the viceroy was represented by eight of his pages. (G. H. B.)

MASAYA, a town in Nicaragua, Central America, on the east side of the Lake of Masaya, about 55 miles south-east of Managua, and 25 miles north-west of Granada. The population, mostly of Indian blood, is estimated at 15,000 or 18,000; but, as nearly every house has its orchard or garden, the buildings are spread over a much larger area than this would suggest. Previous to 1871, when a steam-pump was erected, all the water required had to be carried from the lake, which lies 340 feet below the level of the town. The volcano of Masaya on the opposite side of the lake was active at the time of the conquest of Nicaragua in 1522, and the conquerors, thinking the lava they saw was gold, had themselves lowered into the crater at the risk of their lives; it had a great eruption in 1670, and began to smoke again in 1860.

MASCARA, a fortified town of Algeria in the province of Oran, 60 miles south-east of Oran, lies at a height of 1900 feet above the sea, on the southern slope of the first chain of the Atlas mountains, and occupies two small hills separated by the Oued Toudman. The walls, upwards of 2 miles in circuit, and strengthened by bastions and towers, give the place a somewhat imposing appearance; the French part of the town is substantial and clean; and among the public buildings are three mosques (one used as a church, another as a granary), a large hospital, a small theatre, and the usual establishments attaching to the seat of a sub-prefect and the centre of a military subdivision. A public garden of 10 acres has been laid out in the ravine. The population was 9442 in 1866, and 9240 in 1872.

Mascara (*i.e.*, place of soldiers) was the capital of a beylik during the Spanish occupation of Oran from the 16th to the close of the 18th century; but for the most of that period it occupied a site about 2 miles distant from the present position. On the removal of the bey to Oran its importance rapidly declined; and it was quite an insignificant place when in 1832 Abd-el-Kádir, who had been born in the neighbourhood, chose it as the seat of his power. It was laid in ruins by the French under Marshal Clausel and the duke of Orleans in 1835, and, being again occupied by Abd-el-Kádir in 1838, was again captured in 1841 by Bugeaud and Lamoricière.

MASCARENE ISLANDS, or MASCARENHAS, a group in the Indian Ocean to the east of Madagascar, consisting of Mauritius (Île de France), Réunion (Bourbon), and Rodriguez. Mauritius and Rodriguez belong to Great Britain, Réunion to France. The collective title is derived from the Portuguese navigator Garcia Mascarenhas, by whom Bourbon, at first called Mascarenhas, was discovered in 1505.

MASCARON, JULES, was born at Marseilles in 1634, and died at his diocesan city of Agen in 1703. His father was an advocate, and he was himself intended for the law, but he preferred the church. As a member of the Oratorian congregation he preached in different provincial towns, beginning with Saumur, and in all produced a great effect. Then he went to Paris and quickly established his reputation at a time when the court, dissolute enough in manners, had already begun to exercise its connoisseurship in matters of sacred eloquence. Several complimentary speeches of Louis XIV. to Mascaron are handed down by tradition. He was not, however, in the ordinary sense a courtier; or if so he was a very bold and adroit one. In Lent 1669 he preached before the king against adultery in the strongest terms. Either from respect for him or to get rid of him Louis made him bishop of Tulle, but he still continued occasionally to preach and to deliver *oraisons funèbres* before the court. His reputation for these was so high that the king not unfrequently indicated subjects to him himself. His crowning success in this way was his funeral sermon on Turenne in 1675. He was afterwards translated to Agen, where he died, as has been said; but his appointment was not a banishment, and he was summoned more than once to preach before the court, notably in his sixtieth year, when Louis is said to have remarked to him, "Votre eloquence n'a pas vieilli." Mascaron, though the contemporary of Bossuet, belongs to an older school of oratory. His style is unequal, and his taste not always sure, but occasionally he has much vigour. Besides the Turenne address his funeral sermon on the chancellor Séguier ranks as his chief performance. These, with other similar pieces, were collected and edited by Father Borde, a member of the author's own congregation, in 1740.

MASCHERONI, LORENZO (1750–1800), an Italian geometer, was professor of mathematics at the university of Pavia, and published a variety of mathematical works, the best-known of which is his *Geometria del Compasso* (Pavia, 1797), a body of constructive geometry in which the use of the circle alone is postulated. Many of the solutions are most ingenious, and some of the constructions of considerable practical importance.

The English reader will find a copious extract from Mascheroni's work in Leslie's *Geometry*, 3d ed., p. 204. There is a French translation by Carette (Paris, 1798), who also wrote a biography of Mascheroni.

MASINISSA, a Numidian prince whose history is closely intertwined with that of the wars between Rome and Carthage. With true barbarian fickleness, and a keen eye to his own interests, he espoused now one side now the other, inclining however on the whole decidedly in favour of Rome, so much so indeed as to be spoken of by Roman orators and historians as "a most faithful ally of the Roman people." He was the son of a Numidian king or chief, Gala, whose dominions coincided with the eastern portions of Numidia, and thus bordered on Carthaginian territory, or what is now Tunis. He was educated, like many of the Numidian chiefs, at Carthage, learnt Latin and Greek, it is said, and was in short an accomplished as well as a naturally clever man. Although his kingdom was nominally independent of Carthage, it really stood to it in a relation of vassalage; it was directly under Carthaginian influences, and was imbued to a very considerable extent with Carthaginian civilization. It was to this that Masinissa owed his fame and success; he was a barbarian at heart, but he had a varnish of culture, and to this he added the craft and cunning in which Carthaginian statesmen were supposed to excel. While yet a young man, he drove his neighbour Syphax, prince of western Numidia, out of the country now known as Algiers, and forced him to fly to the Moors in the extreme west of Africa. Soon afterwards he appears in Spain, fighting for Carthage with a large force of Numidian cavalry against the Romans under the two Scipios. The defeat of the Carthaginian army in 206 B.C., which for a time at least gave the Romans complete mastery of the south of Spain, led him to desert his old allies and to cast in his lot with the fortunes of Rome. The famous Scipio Africanus is said to have cultivated his friendship

and done all he could to secure his services for his country. Masinissa now quitted Spain for a while for Africa, and was again engaged in a war with Syphax, in which he was so decidedly worsted that he found himself at last merely the head of a small band of marauders, and was obliged to confine his movements to the coast. Scipio's arrival in Africa in 204 gave him another chance, and no sooner had he joined the Roman general than he quite crushed his old enemy, Syphax, and captured Cirta (Constantineh), the capital of Syphax. Here occurs the romantic story of Sophonisba, daughter of the Carthaginian Hasdrubal, who had been promised in marriage to Masinissa, but who had subsequently become the wife of Syphax. Masinissa, it is said, wedded her immediately after his victory, but was required by Scipio to dismiss her as a Carthaginian, and consequently an enemy to Rome. To save her from such humiliation he sent her poison, with which she destroyed herself. Masinissa was now accepted as a thoroughly loyal ally of Rome, and was confirmed by Scipio in the possession of his hereditary kingdom. In the decisive battle of Zama, 202 B.C., which witnessed Hannibal's downfall, he commanded the cavalry on Scipio's right wing, and materially assisted the Roman victory. For his services on that great day he had given him, under a treaty with Rome, the kingdom of Syphax with its capital Cirta, and thus under Roman protection he became master of the whole of Numidia, and his dominions completely enclosed the Carthaginian territories, now straitened and reduced at the close of the Second Punic War.

Masinissa was still far from satisfied, and it would seem that he almost had thoughts of annexing Carthage itself with the connivance of Rome. He spared no opportunity to harass and annoy the city by pressing unfair claims to some of its best and oldest possessions, and threatening perpetual encroachments. In a war which soon followed he was successful; the remonstrances of Carthage with Rome on the behaviour of their ally were answered by deputing Scipio to arbitrate in the quarrel, but, as though intentionally on the part of Rome, no definite settlement was arrived at, and thus the relations between Masinissa and the Carthaginians were still unfriendly. Rome, it is certain, deliberately favoured her ally's unjust claims with the view of keeping Carthage weak. Masinissa too was cunning enough to retain the friendship and good opinion of the Roman people by helping them with liberal supplies in their wars in the East, with Perseus of Macedon and with Antiochus. As soon as Carthage seemed to be recovering herself, and some of Masinissa's partisans were driven from the city into exile, his policy was to alarm the fears of Rome, till at last, in 149, war was declared, the Third Punic War, which ended in the final and utter overthrow of Carthage. The king bore some part in the negotiations which preceded the war, and died soon after its commencement in 148 B.C., after a life of ninety and a reign of sixty years.

Masinissa was an able ruler and a decided benefactor to Numidia, the resources of which he developed, while he converted a people which had been little better than a plundering tribe into a settled and civilized population, and out of robbers and marauders made efficient and disciplined soldiers. To his sons he bequeathed a well-stored treasury, a formidable army, and even a fleet. Cirta, his capital, became a famous centre of Phœnician civilization. In fact Masinissa changed for the better the whole aspect of a great part of northern Africa. He had much of the Arab nature, was singularly temperate, and equal to any amount of fatigue. His fidelity to Rome was not the fidelity of principle, but merely that of temporary expediency; it is in the really good work he did for his country that the noblest side of his character comes into display.

For Masinissa, Livy and Sallust's *Jugurtha* must be specially consulted by scholars. English readers may be referred to a very full article in Smith's *Dictionary of Classical Biography*; also to Mommsen's *History of Rome* and Niebuhr's *Lectures*.

MASK, or MASQUE. See DRAMA, vol. vii. p. 431 *sq.*

MASKELYNE, NEVIL (1732–1811), astronomer-royal at Greenwich for nearly half a century, was born in London October 6, 1732. The great solar eclipse of 1748 seems to have made a deep impression upon him; and after studying divinity at Trinity College, Cambridge, of which he was elected a fellow in 1756, he determined to devote himself wholly to astronomy. He early became intimate with Bradley, and in 1761 was deputed by the Royal Society to make observations of the transit of Venus at St Helena. During the voyage he introduced into navigation the determination of longitude by lunar distances, a method which Mayer's recently published tables had made practically possible. In 1763 he undertook a voyage to Barbados to test Harrison's watches, which, however, he reported to be inferior to the method of lunars for determining longitude. In 1765 he succeeded Bliss as astronomer-royal, and thereafter devoted himself with singular energy to the duties of his office, which he held till his death, February 9, 1811.

Maskelyne's first contribution to astronomical literature was "A Proposal for Discovering the Annual Parallax of Sirius," published in 1760 in the *Philosophical Transactions*, in which also most of his later original memoirs appeared—*e.g.*, his observations of the transit of Venus (1761 and 1769), observations on the tides at St Helena (1762), astronomical observations at St Helena (1764) and at Barbados (1764). In 1763 he published a small octavo, *The British Mariner's Guide*, which contains the valuable suggestion that, in order to facilitate the finding of longitude at sea, lunar distances should be calculated beforehand for each year and published in a form accessible to navigators. This suggestion, the germ of the *Nautical Almanac*, was approved of by the Government, and under the care of Maskelyne the *Nautical Almanac* for 1767 was published in 1766. During the remainder of his life Maskelyne continued to superintend the publication of this invaluable annual, the *Nautical Almanac* for 1815 being the last which he prepared. Another valuable service which he rendered astronomy was his inducing the Government to print his observations annually. Flamsteed's and Bradley's observations had been private property, and were published as such. The result of Maskelyne's action was the accumulation and rapid dissemination of a long series of observations which from their continuity and accuracy have been of inestimable value to astronomers, and form along with the *Nautical Almanac* his most lasting monument. The whole work of the observatory was carried on by him and his one assistant in a most methodical manner, Greenwich being in point of organization second to none amongst the observatories of the day. He introduced several improvements in the use of the instruments, being, for example, the first astronomer who measured to tenths of a second; and he prevailed upon the Government to replace Bird's mural quadrant, which had become untrustworthy, by a repeating circle of 6 feet in diameter. The new instrument was constructed by Troughton; but Maskelyne did not live to see it completed. In 1772 he suggested to the Royal Society the famous Schehallion experiment for the determination of the earth's density. Forty years previously Bouguer had demonstrated by experiment that Chimborazo in South America affected the direction of the plumb-line quite appreciably; but his observations were not made with sufficient care to deduce therefrom any trustworthy result. Maskelyne's experiments were made in 1774 (see *Philosophical Transactions* for 1775), the apparent difference of latitude between two stations on opposite sides of the mountain being compared with the real difference of latitude obtained by triangulation. From Maskelyne's observations Hutton deduced by laborious calculations that the density of the earth was 4·5 times that of pure water. Playfair subsequently estimated with greater accuracy the mass of Schehallion, and obtained 4·7 for the earth's mean density. Maskelyne also took a great interest in various geodesical operations, notably the measurement of the length of a degree of latitude in Maryland and Pennsylvania (*Philosophical Transactions*, 1769), which was carried out by Mason and Dixon in 1766–68, and later the determination of the relative longitude of Greenwich and Paris (*Philosophical Transactions*, 1787). Cassini, Legendre, and Méchain conducted the triangulation on the French side; on the English side the work was carried on under the superintendence of General Roy. This triangulation was the beginning of the great trigonometrical survey which has since been extended all over the country. A volume of *Selections* (London, 1812) contains several papers that were published by Maskelyne as additions to the *Nautical Almanac*. His observations fill three large folio volumes, and many of them were reprinted in Vince's *Astronomy*.

MASKINONGE. See PIKE.

MASOLINO DA PANICALE (1383–*c.* 1440). The life and art-work of this Florentine painter were related by Vasari in a form which is partly demonstrated and partly inferred to be highly incorrect. We shall follow the account supplied, and in many respects carefully vouched, by Messrs Crowe and Cavalcaselle.

Masolino (a name which corresponds to "Tommy") was said to have been born at Panicale di Valdelsa, near Florence. It is more probable, however, that he was born in Florence itself, his father, Cristoforo Fini, who was an "imbiancatore" or whitewasher, having been domiciled in the Florentine quarter of S. Croce. There is reason to believe that Tommaso, nicknamed Masolino, was a pupil of the painter Starnina, and was principally influenced in style by Antonio Veneziano; he may probably enough have become in the sequel the master of Masaccio. His birth took place in 1383; his death later than 1429, perhaps as late as 1440. The only works which can with certainty be assigned to him are a series of wall paintings executed towards 1428, commissioned by Cardinal Branda Castiglione, in the church of Castiglione d'Olona, not far from Milan, and another series in the adjoining baptistery. The first set is signed as painted by "Masolinus de Florentia." It was recovered in 1843 from a coating of whitewash, and is not a little damaged; its subject-matter is taken from the lives of the Virgin and of Sts Lawrence and Stephen. The series in the baptistery relates to the life and death of John the Baptist. The reputation of Masolino had hitherto rested almost entirely upon the considerable share which he was supposed to have had in the celebrated frescos of the Brancacci chapel, in the church of the Carmine in Florence; he was regarded as the precursor of Masaccio, and by many years the predecessor of Filippino Lippi, in the execution of a large proportion of these works. Now, however, from a comparison of the Castiglione with the Brancacci frescos, and from other data, it is greatly doubted whether Masolino had any hand at all in the latter series. Possibly he painted in the Brancacci chapel certain specified subjects which are now either destroyed or worked over. Of other and still existing subjects, hitherto assigned to Masolino on the authority of Vasari and later writers, the authorship is now more reasonably ascribed to Masaccio,—except only that one compartment, that which represents in one half Peter reviving Tabitha (or curing Petronilla), and in the other half Peter and John healing a cripple, remains in suspense between Masaccio and Masolino. In the Castiglione frescos there is some tenderness of expression, and the nude figures are studied with an amount of care superior to their epoch; generally the parts are well made out, but without unity of composition, or mastery of perspective, or of contrast and chiaroscuro. The merit of these works is not to be compared with that of the Brancacci frescos, unless in the single instance above excepted.

The now ascertained facts of Masolino's life are that towards 1423 he entered the service of Filippo Scolari, the Florentine-born obergespan of Temeswar in Hungary, that he stayed in consequence some time in that country, and that, returning towards 1427 to Italy, he painted the works in Castiglione. Thus he resettled in Lombardy, not in Florence; nor is there anything to show that he returned to his Tuscan home at a later date.

MASON, Francis (1799–1874), an American missionary, son of a shoemaker in York, England, was born April 2, 1799. After emigrating to the United States in 1818, he practised there the trade he had learned from his father; but, having studied languages with his minister at Canton, Massachusetts, he in 1827 entered the Newton theological institution. In 1830 he was sent by the American Missionary Union to labour among the Karens in Burmah, where he translated the Bible into two dialects of their language, and also conducted a training college for native preachers and teachers. In 1852 he published a book of great value on the fauna and flora of British Burmah, of which an improved edition appeared in 1860 under the title *Burmah, its People and Natural Products*. He was also the author of a grammar and vocabulary of the Pali language, besides various translations from it and other Indian dialects. He died at Rangoon, March 3, 1874. See his autobiography, *The Story of a Working Man's Life, with Sketches of Travel*, 1870.

MASON, George Hemming (1818–1872), A.R.A., was born at Whitley, in 1818, the eldest son of a Staffordshire county gentleman. Intended for the medical profession, he studied for five years under Dr Watt of Birmingham; but he had no taste for science; all his thoughts were given to art. In 1844 he abandoned medicine and travelled for a time on the Continent, visiting France, Germany, and Switzerland, and finally settling in Rome. His pencil was busy with the picturesque scenery that surrounded him, and with hardly any instruction, except that received from nature and from the Italian pictures that met his eye, he gradually acquired the painter's skill. At least two important works are referable to this period,—Ploughing in the Campagna, shown in the Royal Academy of 1857, and In the Salt Marshes, Campagna, exhibited in the following year. After Mason's return from the Continent, in 1858, when he settled at Wetley Abbey, he continued to paint Italian subjects from studies made during his foreign tour, and then his art began to touch, in a wonderfully tender and poetic way, the peasant life of his native England, and especially of his native Staffordshire, and the homely landscape in the midst of which that life was set. The first picture of this class was Wind on the Wolds, and it was followed—along with much else—by the painter's three greatest works—the Evening Hymn, 1868, a band of Staffordshire mill-girls, seen, their figures dark against the sunset, returning from their work, singing as they walk; Girls Dancing by the Sea, 1869; and the Harvest Moon, 1872. Mason had long suffered from heart disease, which carried him off on the 22d of October 1872. In his work he laboured under the double disadvantage of feeble and uncertain health, and a want of thorough art-training, and consequently his pictures were never produced easily, or without strenuous and long-continued effort. His art is great in virtue of the solemn pathos which pervades it, of the dignity and beauty which it reveals in rustic life, of its keen perception of noble form and graceful motion and of rich effects of colour and subdued light. In *motif* and treatment it has most in common with the art of Millet and Jules Breton, and of Frederick Walker among Englishmen. An interesting collection of Mason's pictures was brought together by the Burlington Club shortly after his death.

MASON, William (1725–1797), was about the beginning of the last quarter of the 18th century one of the most eminent of living poets, but his eminence was owing to the lowness of the poetic level at the time. He is now held in remembrance, not by his poetry, but by his having been the friend, the literary executor, and the biographer of Gray. Born in 1725, the son of a Yorkshire clergyman, entered of St John's College, Cambridge, in 1742, he took his bachelor's degree in 1745, and seems to have at once decided steadily on a literary career, reading little or nothing, Gray says, but writing abundance. Pope died in 1744, and the aspiring young poet lamented him as "Musæus" in a careful imitation of Milton's *Lycidas*, showing an ear for the music of verse and considerable skill in weaving words together, but not a spark of original force. By his *Musæus* (1747) Mason attracted the

notice of Gray, and through his influence was elected a fellow of Pembroke College. Mason was Gray's attached friend, admirer, and poetical pupil to the end of the greater poet's life. More fancy than judgment, and indolence in reading, were the chief faults that Gray found in his young friend. With his usual penetration, Gray discerned the defects of intellect that lie at the root of the weakness of Mason's poetry. He was painstaking enough and more than enough with his verses, his epithets, his phrases, his figures of speech, his rhymes; but he was deficient in energy of thought, his intellectual grasp was feeble, and he accepted and polished the easy suggestions of fancy instead of exerting himself to find exact expression for his subject. For a modest youth, as Gray describes him, he formed a great ambition, nothing less than the reconciliation of the modern with the ancient drama, to be effected by the strict observance of the unities and the restoration of the chorus. His *Elfrida*, a tragedy published in 1752 in pursuance of this ambition, is constructed elaborately upon deeply considered principles, but the principles are drawn from pedantic books and not from the dramatic needs of men, as may be judged from the dramatist's opinion that Shakespeare, "in compliance merely with the taste of the time, showed a disregard of all the necessary rules of the drama." *Elfrida* is highly "incorrect" in two respects—one venial in a play, the other fatal; it abounds in anachronistic allusions and moral improbabilities. Mason's second attempt, *Caractacus* (published in 1759), is much stronger in construction and situation, but he did not possess the rare art of making his characters speak out of their own thoughts; they only speak as Mason the poet might have done in their circumstances if his fancy had been quite cool. Both *Elfrida* and *Caractacus* were acted in 1776, when Mason had made a considerable reputation by his *English Garden* (a poem in blank verse, first book published in 1772), his *Heroic Epistle to Sir W. Chambers* in 1773, and his *Memoirs of Gray* in 1775. The plays were not successful; Mason did not expect success; his plays were intended to be read as poems. The manager perhaps had hopes from the novelty of the choruses of Saxon maidens and Druids. The second book of the *English Garden* was issued in 1777, the third in 1779, the fourth in 1782. Mason took orders in 1754, and soon afterwards was presented to the vicarage of Ashton in Yorkshire, the canonry of York, the prebend of Driffield, and the precentorship of York cathedral. Ashton was his residence till his death in 1797.

MASON AND DIXON'S LINE, a line in the United States between Pennsylvania on the north and Delaware, Maryland, and West Virginia on the south, coinciding with 39° 43′ 26″·3 N. lat., and famous for a long time as the limit between the "free" and the "slave" States. It derives its name from Charles Mason, F.R.S. (1730–87), and Jeremiah Dixon, two English astronomers who, between 1763 and 1767, surveyed the line for 244 miles west from the Delaware river, leaving only 36 miles of the Pennsylvania boundary to be fixed in 1782–84. This line must not be confounded, as has often been done, with the parallel of 36° 30′ N. lat., which was assigned by the "Missouri compromise" of 1820 as the limit to the north of which slavery could not be introduced.

MASS. See EUCHARIST and MISSAL.

MASSA, or, to distinguish it from several places of the same name, MASSA CARRARA, a city of Italy, the chief town of the province of Massa, lies on the left bank of the Frigido, a small stream falling into the Gulf of Genoa about 3 miles lower down. It is 78½ miles south-east of Genoa by rail, and 26 miles north of Pisa. The ancient part of the city stands on a hill. Among the objects of interest it is sufficient to mention the old ducal palace, the new cathedral (erected instead of the building destroyed by Elisa Bacciocchi because it interfered with the view from the palace windows), the technical school, and the academy of science and literature, originally known as Dei Derelitti. Like Carrara, Massa is largely engaged in the marble trade; it also manufactures silk, oil, and paper. The population of the city was 4786 in 1871; that of the commune was 15,017 in 1861 and 18,031 in 1881.

Massa is first mentioned in the 9th century. About the close of the 10th it was bestowed by Otho the Great on the bishops of Luni, and in consequence it came to be distinguished for a time as Massa Lunense. From the bishops it passed to the marquises of Luni (hence *Massa del Marchese*), and more particularly to a branch of the Malaspina family. After a period in which Lucca, Pisa, the Visconti, the Fieschi, and others were successively in possession it returned, under Florentine protection, to Alberico Malaspina, and finally through the marriage of Ricciarda Malaspina with Lorenzo Cybo became (1519) *Massa Cybea*. Raised under Alberico Cybo from being little better than a feudal village to the rank of a fortified town, Massa was in 1568 made the capital of a principality by Maximilian II., and in 1664 the capital of a duchy by Leopold I. By the marriage of Maria Teresa dei Cybei with Duke Ercole III. of Modena it passed to the Este family; and after the period of the French Revolution, during which it formed part of the duchy of Lucca assigned to Napoleon's sister and brother-in-law, it was restored by the congress of Vienna to Beatrice, duchess of Modena. Massa was made an episcopal see only in 1828, though the design of giving it this dignity had been entertained and almost realized in 1757. The total area of the duchy of Massa and Carrara was 62 square miles, of which 35 belonged to Massa.

See Repetti, *Diz. della Toscana*; Viani, *Memorie della famiglia Cybo*; Muselini, *Ricciarda Malaspina e Lorenzo Cybo*; and Farsetti, *Ragion. storico int. della città di Massa.*

## MASSACHUSETTS.

Plate IX.

MASSACHUSETTS, a New England State of the American Union, is one of the thirteen original states of the Confederacy of 1776–1788. It lies between latitudes 41° 15′ and 42° 53′ north, and longitudes 7° 30′ and 73° 30′ west. The name is an Indian one, applied at first to the hills near the coast and afterwards to a tribe of Indians, and finally was given to the State. Massachusetts is bounded on the north by Vermont and New Hampshire, on the east by the Atlantic ocean; on the south by the Atlantic, Rhode Island and Connecticut, and on the west by Rhode Island and New York. The length of the State from east to west is 160 miles, and from north to south it measures 50 miles, except where two projections, one on the southeast and another on the northeast coast, give it a width of 90 miles. The irregular coast line, which is in the form of the toe of a boot, gives the State about 150 miles of sea coast line.

The surface of the State is uneven and almost mountainous in places. There are two ranges of the Green mountains in the State, the Hoosic and the Taghkanic. These mountains running north and south through the western part of the State furnish some of the most picturesque scenery to be found in all New England. The most westerly of these ranges is the Taghkanic. The principal elevations of the range are, Saddle mountain, more commonly known as Greylock, which is 3,505 feet high, and Mt. Everett, 2,624 feet high. Mt. Tom is 1,200 feet in height, and Wachusett, in the eastern part of the State, 2,018 feet. The Connecticut is the largest river in Massachusetts, and is fed by several small streams; but none of the rivers are navigable, except for small craft. The Housatonic river has its course parallel with the Connecticut and flows through the western part of the State. It is separated from the Connecticut by the Hoosic mountain. The Merrimac, which rises in New Hampshire, flows for the last 35 miles of its course through the northeast corner of the State. This river furnishes valuable water power to manufactories in Lowell, Haverhill and Lawrence.

The principal rivers in the eastern part of the State are the Charles, at whose mouth is the city of Boston, and the Blackstone, with inexhaustible water power. In the west is also the Hoosic river, which rises in the northwest corner of the State, soon passes beyond its limits, and flowing through New York, empties into the Hudson. The Westfield and Deerfield rivers are both tributary to the Connecticut. There are many exceedingly beautiful lakes in Massachusetts, but they are too small to be of any consequence for navigation. Cape Cod and Cape

Ann form the outer arms of Massachusetts Bay. On the western side of this bay is Boston Harbor which is said to be the finest roadstead on the coast. Provincetown harbor is on the extreme hook of Cape Cod and furnishes protection to vessels approaching Boston. It is a spacious port and stands next to Boston among the harbors of the State. Salem harbor or Massachusetts bay is a very good roadstead and on Buzzard's Bay, New Bedford has a very capacious and safe port. Besides these there are Nantucket, Wellfleet, Vineyard, Edgertown, Nahant, Marblehead, Lynn, Beverly, Gloucester and Annisquam. The shore south of Cohasset is low and sandy; about Boston and further north it is rocky and rough.

The principal islands of Massachusetts lie off the southern coast. Martha's Vineyard is 21 miles long with an average width of five or six miles. Holmes' Hole is the most spacious harbor on the island. Mayhew's missionary efforts among the Indians were conducted here. The island has a population of about 4,500. Nantucket is about fifteen miles long and eleven miles wide at its eastern end. The shape of the island is that of a triangle. The population is about 4,000. Most of the male inhabitants are engaged in seafaring and the fishing business. These islands are much frequented now by summer tourists. Besides these islands there are the Elizabeth groups, of sixteen islands, off Cape Cod.

*Climate.*—The climate is cool but very trying. The winters are long and severe, the summers short and subject to very hot periods, which are of brief duration. Snow falls during five or six months and sometimes even seven in the course of the year. The rainfall is very equably distributed through the seasons, and has been, for a number of years, between 40 and 43.5 inches per year. The thermometer ranges from 25° Fahr. below zero to 100° above. The mean average temperature is about 40° Fahr. The ocean tempers the climate considerably on the sea coast. The changes are often very sudden and the passage from winter to spring is rapid, making the spring season short. The prevailing winds on the coast are from the east; in the interior, from the north.

*Vegetation.*—Much of the soil of Massachusetts is sterile. The southeastern part is sandy and flat. Here there never has been any vegetation of any account; but the other parts of the State were formerly covered with deciduous trees such as oak, chestnut, ash, maple, hickory. On the hill tops and mountain sides, pine and hemlock grew. Nearly all the flora found in the New England States and Eastern New York are natives of Massachusetts. When the forests were cut down, the land was found to be of poor quality and it has required the utmost toil to make its cultivation profitable, except in the river valleys.

*Zoölogy.*—The larger animals have been exterminated; but foxes, squirrels, rabbits and other small game are quite numerous still. Bears, wolves, wild cats, panthers and deer were once numerous, but are very rarely seen now. Owls, hawks, gulls, ducks, partridges and a great variety of song birds are common. The fish in the rivers and along the sea coast are abundant and many of them edible and of excellent quality. Those that have the best reputation, are the cod, halibut, mackerel, haddock, bass and tautog. Under the state commission the artificial cultivation of salmon and other species of fish has been successfully carried on.

*Geology—General.*—Dr. Shaler says: "Topographically as well as geologically, Massachusetts is divided into four sections." The southeastern part is made up of glacial drift. Westward to the Connecticut river the rocks are of the Laurentian, Cambrian and Carboniferous ages. From the Connecticut valley to the New York line the rocks, according to Professor Emerson of Amherst College, are Silurian.

*Geology—Economical.*—All the soils contain phosphates, and the phosphate of lime is invariably present. With few exceptions the soils of the State are entirely destitute of carbonate of lime, while on the other hand the sulphate of lime is almost universally present. A peculiar variety of soapstone has been found in Andover, which, on account of its hardness, may be used in external architecture. The inexhaustible quantity of the serpentine of Lynnfield, on account of its vicinity to Salem and Boston, renders it of great value. Small and irregular veins of a very superior bituminous coal are found in the sandstone of the Agawam river in West Springfield.

Among the ores in the State are carbonate of iron, found very abundantly at Newbury. The magnetic iron found in Warwick is not worked on account of difficulties experienced in its reduction. The valuable chromic iron ore is found in Chester. It occurs in serpentine, in *couches* from 5 to 18 inches wide, and is said to contain traces of platinum. Simonite or hematite is abundant at several places in Berkshire county. Copperas is manufactured at Hubbardston in large quantities.

*Scenographical.*—Massachusetts is peculiarly mountainous. Dr. Hitchcock, who made the first geological survey of the State, says of it: "We find some scenery that is truly Alpine, the sharp, towering peak, the overhanging cliffs, and the roaring torrent beneath, arrest the attention and excite strong emotions! Such objects are numerous in the State, especially in the western part." The principal mountains of Massachusetts are Holyoke, Tom, Hoosic, Wachusett, Toby, Sugar Loaf, Lincoln and Deerfield.

*Scientific.*—The highest parts of Massachusetts and in fact all the northern parts of the continent of North America have been swept over by a powerful current from the northwest to the southeast. In Massachusetts, we have Mt. Everett, not less than two thousand six hundred feet high, and Wachusett, not less than three thousand feet high, both bearing marks of powerful erosion, and standing as isolated peaks, hundreds of feet above the surrounding country. This erosion must have been due to diluvial waters, icebergs and glaciers. To these agencies also must be attributed the "drift" of stones, gravel, etc., that are found everywhere in the State.

*Population.*—The population of the State May 1, 1885, was 1,942,141 as against 1,651,912 May 1, 1875. The gain for the decade was 290,228 or 17.57 per cent. By the national census of 1890, the population was 2,238,943.

| Census Years. | Males. | Females. | Population. | Percentage. | |
|---|---|---|---|---|---|
| | | | | Males. | Females. |
| 1885 | 932,884 | 1,009,257 | 1,942,141 | 48.03 | 51.97 |

| Color and Race. | Year. | Native. | Foreign. | Total. |
|---|---|---|---|---|
| The State | 1885 | 1,415,274 | 526,867 | 1,942,141 |
| White | 1885 | 1,398,234 | 524,710 | 1,922,944 |
| Black | 1885 | 11,917 | 1,082 | 12,999 |
| Mulatto | 1885 | 4,731 | 605 | 5,336 |
| Chinese | 1885 | 2 | 430 | 432 |
| Japanese | 1885 | ..... | 20 | 20 |
| Indian | 1885 | 390 | 20 | 410 |

*Agriculture.*—The soil of Massachustts is, for the greater part, sterile. The southeastern part is barren and sandy. In the neighborhood of the large cities there are rich markct gardens made productive by high cultivation. The valleys are rich and fertile, and the soil in the Connecticut river valley is as productive as can be found, even in the Western States. There was in the State in 1885, 239,260 acres of cultivated land, 1,479,454 acres of improved land, of which 90,212 acres are unimprovable. Woodland comprised 1,389,501 acres. Of the total acreage of cultivated land in the State, 939,260, acreage for seventeen crops amounted to 753,193, or 80.20 per cent. of the whole cultivated area. The average value of yield per acre, for the seventeen crops was $19.15 on an average value per acre for all cultivated land of $63.76, or a gross return of a little over 30 per cent. per acre. The following shows these seventeen individual products.

| Crops. | Acreage. | Value. |
|---|---|---|
| Barley | 2,219.75 | $ 51,040 |
| Buckwheat | 4,202 21 | 37,347 |
| Indian Corn | 48,485.19 | 1,271,349 |
| Cranberries | 2,900.19 | 540,909 |
| Clover Hay | 11,850 11 | 221,822 |
| English Hay | 393,882.85 | 7,289,829 |
| Meadow Hay | 137,257.04 | 1,365,411 |
| Millet Hay | 5,399.82 | 115,379 |
| Salt Hay | 23,009.48 | 198,081 |
| Hay not classified | 48,110.11 | 486,371 |
| Oats | 18,235.40 | 273,318 |
| Onions | 1,580.44 | 270,115 |
| Potatoes | 33,858 34 | 1,904,225 |
| Rye | 18,350.70 | 164,181 |
| Strawberries | 1,324.64 | 406,895 |
| Tobacco | 2,673.68 | 474,929 |
| Wheat | 253.95 | 7,492 |

The aggregate value of all products for the year was $47,756,444; value of farm buildings, $20,547,431, not including houses. Value of farm implements and machinery $7,397,990, of domestic animals $17,055,153. There are 41,010 farms owned; 3,243 rented; 683 worked on shares.

A large part of the tobacco and onions is raised in the Connecticut river valley, in the portion between Springfield and Greenfield. The farms are largely owned by immigrants now, the native farming population having gone farther west.

*Manufacturers.*—The decrease of capital devoted to production in 1889 as compared with 1888, amounted to 1.44 per cent. The increase in the value of goods made reached 2.45 per cent. In 1888 the average number of persons employed in all the establishments represented was 198,914, and the average number of persons employed in the same establishments in 1889 was 200,685; this is an increase of 0.89 per cent. in the average number employed. The number of persons employed at the periods of employment of the greatest number shows an increase of only 0.06 per cent. in 1889 as compared with 1888, while the number employed at periods of employment of the smallest number shows an increase of 3.82 per cent. The range of unemployment was greater in 1888 than in 1889, the number unemployed at same period, of longer or shorter duration, in the former year being 51,697 as against 45,352 in the latter year, a decrease in 1889 of 12.27 per cent. The average number of persons employed in each establishment during 1889 was 147; the average number employed during each month of the year, in each establishment, ranged from 145 persons to 148 persons.

The average yearly earnings per individual, without regard to sex or age, employed in the 47 industries were $413.19 in 1888, and $419.17 in 1889. The range from highest to lowest average yearly earnings was from $872.14 to $266.67 in 1888, and from $744.74 to $305.44 in 1889. The higher earnings ruled in the industries demanding greater skill and employing males chiefly, and the lower in factory industries employing a large proportion of females and young persons.

The average proportion of business done reached 77.52 per cent. in 1888 and 76.74 per cent. in 1889, of the full productive capacity of the 1,364 establishments compared. In 1888, 917 establishments, and in 1889, 883 establishments ran practically the entire year.

In 1888 there were 563 boot and shoe establishments which turned out goods to the value of $85,605,513. There were 164 cotton goods establishments, which made $88,588,148 worth of goods. There were 287 establishments manufacturing metallic goods. The value of their goods made during the year, was $33,074,810. The value of the goods made by the 133 woolen manufactories in the State was $32,287,945.

The total number of manufactories of all industries was 3,254; the total value of their products was $549,594,985. The average value of goods made per establishment was: Boots and shoes, $152,052; cotton goods, $540,172; metallic goods, $115,247; all industries, $168,930. In the amount of food preparations put up in the State during the year 1889, Massachusetts exceeded nearly every other State in the Union. There were 230 establishments engaged in this line of business; the total value of their products was $52,362,751, the average value of products per establishment was $227,665. Massachusetts stands first in the list of States in the production of cotton and woolen goods, and in the manufacture of boots and shoes. The paper and paper goods industry gives evidence of increasing prosperity. There has been a strong tendency towards a decrease in the number of private firms and an increase in corporations during the past few years.

| | |
|---|---|
| Total value of manufactured products | $ 674,684,269 |
| Total value of agricultural products | 47 756,033 |
| Total value of the fisheries | 6,462,692 |
| Total aggregate | 728,852,994 |
| Total valuation of real and personal estate | 1,782,249,143 |
| Total tax for State, country, city and town purposes | 25,850,317 |
| Rate of total tax per $1,000 | 14.50 |
| Product per individual | 375.28 |
| Valuation per individual | 917.72 |
| Taxation per individual | 13.31 |

*Banks.*—The total assets for 1889 of the 177 savings banks of the commonwealth, $350,072,392, are exceeded by no other State except New York, in which they are $615,889,796. On October 31, 1889, the number of open accounts was 1,029,694; number of deposits, 992,376; amount of deposits not including dividends, $67,609,338; average deposit, $68.13; total earnings, $16,919,069; total ordinary dividends, $13,359,518; total extra dividends, $162,477. This shows an increase in every respect over the previous year.

In the extent of the securities with which it deals, the Boston Stock Exchange stands next to that of New York. The proportion of citizens who hold United States bonds, to the population of the State, is greater than that of any other State in the union.

*Publications.*—The earliest printing in the British colonies was done in this State, in the city of Cambridge. The Cambridge and Riverside presses are to-day among the foremost in the country, and Boston, with New York, Philadelphia and Chicago, ranks as one of the first cities in the amount of business done by its publishing houses. The first regular newspaper, the Boston *Newsletter*, was established as early as 1704. The principal newspapers are published in Boston. The Springfield *Republican*, which is of considerable influence in the western part of the State is published in Springfield. There are in all 441 periodical papers published in the State. Of these 48 are daily, nine semi-weekly, 274 weekly, five bi-weekly, five semi-monthly, 83 monthly, one bi-monthly, 14 quarterly, two annual.

*Railroads.*—The railroad system of Massachusetts is the most complete of all the States. The rivers offer no facilities for transportation, but a perfect network of railways brings nearly every city and town in the State into communication with the great centers. Trunk and branch lines run out of Boston in almost every direction, thus closely connecting the suburban towns with the metropolis. This makes it possible for persons doing business in Boston to have suburban homes, and large numbers take advantage of this opportunity. But few cities in the United States can equal, in any respect, the beautiful outlying towns of Boston. The oldest road in the State is the Boston & Lowell. It was opened for use between these two points in 1835. There are about sixty corporations in the State, but the different lines have so combined that less than twenty-five boards of direction control all the roads. The railroads are under the supervision of a board of railroad commissioners, who are appointed by the State, and vested with large powers. The province of the board is to settle disputes which come up between the different roads, between the roads and the public, to hear and investigate all complaints against the roads, to find out and recommend a remedy, to supervise accounts, examine the condition of tracks, bridges, etc., and to investigate accidents. The cost of this supervision for ten years was one-twentieth of one per cent. of the gross receipts of the roads. The Fitchburg road which runs through the northwest part of the State, goes through the Hoosac tunnel. This tunnel was begun in 1855, but was not completed until 1874. It was cut through almost solid rock for a total distance of four and three-fourths miles. From the top of the mountain a shaft was sunk which meets the tunnel at about half the distance from its two openings and furnishes a means of ventilation.

It cost $14,000,000 to complete this tunnel, for which the State lent its aid and credit. The total number of miles of railroad in Massachusetts in 1889 was 2,571; the length of line operated was 3,371; the capital stock amounted to $126,513,644, funded debt, $87,778,614; total investment, $224,817,677; cost of railroads and equipment, $199,719,221; gross earnings from passenger trade, $19,542,500; from freight, $21,272,746; from all sources, $43,074,206. The net earnings were $10,330,976. Interest paid on bonds amounted to $4,482,927; interest paid on stock, $5,642,256. Poor's railroad manual shows the growth of railroads in the State since 1860 to have been as follows:

| Number of Miles in Operation. | Year. |
|---|---|
| 1,264 | 1860 |
| 1,480 | 1870 |
| 1,915 | 1880 |
| 1,997.80 | 1885 |
| 2,025.87 | 1886 |
| 2,067 60 | 1887 |
| 2,074 32 | 1888 |
| 2,082.77 | 1889 |

*Fisheries.*—The fisheries have always absorbed considerable attention from those living along the shores of Massachusetts. The most important centers of this trade are at Gloucester and New Bedford—Gloucester is unsurpassed for the magnitude of its cod and mackerel fisheries; New Bedford is the leading market for the

products of the whale. The number of vessels in the State engaged in the whale fisheries is about 175, as against 1,000 in the cod and mackerel fisheries. According to the census of 1870 and 1880, about half the products of the whole eastern fisheries of the United States, except the whale fisheries, was the result of Massachusetts labor and enterprise. The following table gives the statistics of the fisheries for Massachusetts for the year 1885:

| | |
|---|---|
| No. of cities and towns engaged in the fisheries | 67 |
| Investments in working capital | $7,367,328 |
| Investments in apparatus | 1,009,913 |
| Investments in salt and ice | 283,340 |
| Total investments | $8,640,581 |
| Value of food fish taken | $4,566,679 |
| Value of fish products | 227,793 |
| Value of food fish products | 2,546 |
| Value of shell fish | 359,257 |
| Value of whale and seal products | 1,270,543 |
| Value of other products | 36,074 |
| Total | $6,462,892 |

| Kind of Vessels. | Number of Vessels. | Tonnage. |
|---|---|---|
| Schooners | 736 | 47,767.29 |
| Sloops | 55 | 352.22 |
| Barks | 62 | 16,985.05 |
| Brigs | 3 | 325.91 |
| Steamers | 3 | 159.03 |
| Ships | 7 | 2,622.00 |
| Total | 866 | 68,211.50 |

| | |
|---|---|
| Number of resident fishermen employed | 11,743 |
| Number of non-resident fishermen employed | 2,933 |
| Number of shore laborers employed | 472 |
| Number of factory hands employed | 149 |
| Number of curers and packers employed | 138 |
| Total | 15,435 |

*Commerce.*—There are twelve collection districts in Massachusetts, and the foreign and domestic commerce of the State is quite extensive. Previous to the age of iron vessels, Massachusetts ranked among the very first, not only in the construction of ocean craft, but also in the amount of goods carried by her vessels to and from her ports. For several years previous to the civil war, steam ship lines had run to Philadelphia and Baltimore, as well as to ports further south. These lines represented Massachusetts capital. The war and the introduction of iron ships broke up her ocean commerce, and directed the capital to railways and manufacturing interests. In 1872 the fire occurred in Boston, which destroyed $72,000,000 worth of property and crippled business enterprises. Business depression throughout the State, from this and other causes, was followed by an era of prosperity. The following table gives a summary of her commercial trades for 1885:

| Kinds of Vessels. | Number of Vessels. | | | | | | |
|---|---|---|---|---|---|---|---|
| | Coastwise. | Ocean. | Coastwise and Ocean. | Total Vessels. | Freight. | Passenger. | Freight and Passenger. |
| The State | 461 | 259 | 77 | 797 | 695 | 20 | 82 |
| Barks | ..... | 81 | 5 | 86 | 82 | ..... | 4 |
| Barkentines | 2 | 12 | 6 | 20 | 19 | 1 | ..... |
| Brigs | 2 | 17 | 4 | 23 | 21 | ..... | 2 |
| Schooners | 334 | 28 | 62 | 424 | 408 | ..... | 16 |
| Ships | ..... | 45 | ..... | 45 | 43 | ..... | 2 |
| Sloops | 39 | ..... | ..... | 39 | 38 | 1 | ..... |
| Steam vessels | 84 | 76 | ..... | 160 | 84 | 18 | 58 |

KINDS OF COMMERCE AND UNDER WHAT FLAG, FOR THE STATE.

| Under What Flag. | Coastwise Commerce. | |
|---|---|---|
| | Number of Vessels. | Tonnage. |
| The State | 461 | 171,660.37 |
| American | 459 | 170,778.37 |
| British | 2 | 882.00 |

| The State, and Kind of Commerce. | Number of Vessels. | Value of Vessels. | Amount Owned by— | | |
|---|---|---|---|---|---|
| | | | Citizens of Massachusetts. | Citizens of Other States. | Foreigners. |
| The State | 797 | $27,910,604 | $9,765,319 | $3,928,031 | $14,217,254 |
| Coastwise | 461 | 9,408,050 | 6,367,053 | 3,029,972 | 11,025 |
| Ocean | 259 | 17,867,954 | 3,060,078 | 611,647 | 14,206,229 |
| Coastwise and Ocean | 77 | 634,600 | 348,188 | 286,412 | ..... |

In 1885 the State contributed more than two and three-quarters millions of dollars as internal revenue to the treasury of the Federal government.

*Health—Births and Deaths.*—A State board of health, lunacy and charity has supervision of the public hygiene and of the institutions for the paupers and insane. The twelve principal causes of fatality in all ages are in the following order: Consumption, pneumonia, diphtheria, heart disease, old age, cholera infantum, cancer, scarlet fever, cephalitis, bronchitis and apoplexy. The number of deaths for 1888, and the order of disease, is as follows:

| | | | |
|---|---|---|---|
| Miasmatic diseases | 7,645 | Developmental Diseases of— | |
| Euthetic diseases | 233 | Children | 3,108 |
| Dietic diseases | 160 | Adults | 159 |
| Parasitic diseases | 4 | Old people | 2,024 |
| Diathetic diseases | 1,759 | Diseases of nutrition | 932 |
| Tubercular diseases | 7,408 | Accident or negligence | 1,485 |
| Diseases of— | | Battle | ..... |
| Nervous system | 5,562 | Homicide | 16 |
| Organs of circulation | 3,191 | Suicide | 164 |
| Respiratory organs | 5,450 | Execution | 1 |
| Digestive organs | 2,290 | Sudden, cause unascertained | 2 |
| Urinary organs | 1,599 | Causes not stated, or ill-defined | 536 |
| Organs of generation | 70 | All causes | 44,040 |
| Organs of locomotion | 136 | | |
| Integumentary system | 106 | | |

For 1888 the births to every 1,000 of the population were more than 26. The total number registered for the year was 54,898, which was larger than that of any year since the beginning of registration in Massachusetts.

The number of deaths reported for the year 1888 was 42,097, which was 1,334 more than the number returned in 1887, and 4,853 more than the number reported in 1886.

It was also greater by 3,929 than the average mortality of the five years ending with 1887, and was the greatest number reported in any year since the beginning of registration.

Estimating the population in 1888 to have been 2,044,506, the death rate for the year was 20.59 per thousand of the living population, which was greater than that of any previous year since 1875, and was also sufficiently large to increase the average mortality rate (19.43) for the thirty-seven years (1851–1887) to 19.48 for the period of thirty-eight years ending with 1888.

*Education.*—In the year 1889 there were six normal schools in the commonwealth, with an attendance for the year of 1,352 pupils, the largest number for any year in the history of these institutions. Their graduates find steady employment in teaching as soon as their course is finished. Of the 8,753 teachers in the State, 3,573 have received a professional training. The number of persons in the State between the ages of five and fifteen was 367,785. The number of all ages in the public schools during the year was 368,166, an increase for the year of 5,000. There was an increase of 5,505 in the average membership of the schools, and an increase of

| | Freight. | | Passengers. | | Amount received for Freight and Passengers. | Average Gross earnings per Vessel. | Percentage of Gross Earnings of Value of Vessels. |
|---|---|---|---|---|---|---|---|
| | Tons Carried. | Amount Received. | Number Carried. | Amount Received. | | | |
| The State | 5,168,186 | $10,731,637 | 13,636,795 | $2,184,337 | $12,915,974 | $16,206 | 46.28 |
| Coastwise | 3,576,231 | 5,186,778 | 13,626,729 | 1,812,375 | 6,999,153 | 15,183 | 74 40 |

6,028 in the average daily attendance for the year. The per cent. of daily attendance was 90. There were 396 private schools—an increase of 48 for the year. The number of pupils attending these schools was 37,620, an increase of 7,000. The Massachusetts system of schools includes the high school, which stands at the head of this system.

There were 336 high schools in the State, an increase of six for the year. Over 90 per cent. of the people live in places supporting high schools. A high school training, such as may now be obtained in the best high schools, will prepare students for the advanced studies of the colleges or the technical school, and for the taking up of the work of practical life.

Two hundred and fifty evening schools were maintained during the year, in fifty-one cities and towns, with an attendance of 12,598 pupils. The statutes require every town to provide a suitable place for the confinement, discipline and instruction of its truant children. In 1884 an act was passed which provides that the school committee of every city and town shall purchase, at the expense of such city or town, text books and other school supplies used in the public schools, to be loaned to the pupils free of charge.

In the 7,023 public schools in the State, there were 10,123 persons employed as teachers; 901 were men, 9,222 were women. The average wages paid to male teachers was $108.88 per month. Average wages paid to women was $45.93 per month.

| | |
|---|---|
| Average number of months the public schools have kept | 8–11 |
| Amount of salaries paid to principals of high schools | $ 302,209.14 |
| Expense of evening schools | 127,942.05 |
| Amount raised by taxation for support of public schools, wages of teachers, fuel and janitors | 5,366,605.29 |
| Amount expended 1888-89 for new schoolhouses | 614,508.54 |
| Income of local school funds | 113,774.69 |
| Income of funds appropriated by towns, as surplus revenue, dog tax, etc. | 95,311.19 |
| Income of school fund paid to cities and towns | 62,924.04 |
| Towns using other than public school buildings | 31 |
| Number of school buildings | 3,439 |
| Value of buildings | $23,222,781 |
| Value of property | 1,042,428 |
| Total number who cannot read | 133 |
| Total number who cannot write | 25,360 |
| Total number who cannot write nor read | 96,770 |
| Total illiterate | 122,263 |
| Of these the foreign born are | 108,365 |
| Born in Massachusetts | 9,297 |

At South Boston there is a school for the feeble minded. The following table shows the condition of the school:

| | Males. | Females. | Totals. |
|---|---|---|---|
| Number of pupils present Sept. 24, 1888 | 109 | 85 | 194 |
| Admitted during year | 18 | 10 | 28 |
| Whole number present during year | 127 | 95 | 222 |
| Discharged during year | 9 | 8 | 17 |
| Died during year | 2 | 1 | 3 |
| Number of pupils present Sept. 30, 1889 | 116 | 86 | 202 |
| Average number present during year | | | 198 |
| Private pupils now present | 13 | 5 | 18 |
| School beneficiaries of Massachusetts | 50 | 36 | 86 |
| Custodial cases supported by the State | 10 | 14 | 24 |
| Custodial cases supported by cities and towns | 31 | 27 | 58 |
| Beneficiaries of other New England States | 12 | 4 | 16 |
| Number at farm included above | 23 | | 23 |
| Applicants for admission during year | 76 | 46 | 122 |

There is, also, at the same place, a public school for the blind—Perkins Institute—under whose auspices is also conducted a kindergarten for blind children.

Of the higher institutions, the more important are Harvard University, founded in 1636, Amherst College, Williams and Tufts. Smith, Mount Holyoke and Wellesley are colleges for women. These, together with Clark University at Worcester, the Massachusetts School of Technology, and the Massachusetts Agricultural College, also at Amherst, and a score of lesser institutions furnish college homes for students from every State and almost every city and town in the Union.

Massachusetts has been the home of some of our most noted American citizens, in politics, letters, history, science, philosophy and religion. In her political history the names of Samuel Adams, John Adams, John Quincy Adams, James Otis, Fisher Ames, Webster, Choate, Sumner, Everett, Phillips and Winthrop figure prominently. In science there are such men as John Winthrop, Benjamin Pierce, Morse and Agassiz. In history, Hutchinson, Bancroft, Prescott, Motley, Sparks and Parkman are recognized universally as authorities. In letters there are the names of Richard Henry Dana, Longfellow, Bryant, Whittier, Lowell and Holmes. As expounders of religion and philosophy, Jonathan Edwards, Channing, Emerson, Parker and Phillips Brooks; as writers of story, Hawthorne, Mrs. Stowe, Howells and T. B. Aldrich, not to mention scores of others in all departments of polite learning and letters whose names are household words all over the country.

*Libraries and Reading Rooms.*—There are 194 reading rooms in the State. The total number of newspapers and periodicals taken by these reading rooms in 1889 was 8,816; the number of books of reference was 9,332; the total number of persons who visited these reading rooms was 2,107,260. The 2,371 libraries in the State were divided as follows:

| | | | |
|---|---|---|---|
| The State | 2,371 | Secular— | |
| Secular | 765 | Artistic | 1 |
| City public | 32 | Law | 15 |
| Town public | 209 | Medical | 12 |
| Other public | 7 | Hospital | 11 |
| Association | 156 | Reference | 5 |
| Private circulating | 117 | Institution | 20 |
| Public school | 52 | Religious | 1,668 |
| Private school | 42 | Church | 33 |
| Public and private school | 1 | Church and Sunday School | 13 |
| College | 12 | Sunday School | 1,583 |
| Scientific | 11 | Association | 39 |

*Government.*—The constitution of the State is the same, with the exception of the addition of some amendments, under which the State was organized in 1780. Under this constitution the executive department of the State consists of a governor, a lieutenant-governor, a secretary, treasurer and auditor. The governor and lieutenant-governor, with eight others, representing the eight divisions of the State, form the executive council. The governor is also assisted by a military staff, as he is, *ex-officio*, commander in chief of the militia. The attorney-general is the legal officer for the State. These officers are chosen by the legal voters of the State on the Tuesday after the first Monday in November and they hold office for one year. Forty senators and 240 representatives from their several districts are elected at the same time and hold office for one year. These form the legislature of the State, known as the General Court of Massachusetts. Every male citizen, 21 years of age, able to read the constitution in English and write his name, who has resided in the State one year, and in the district in which he votes, six months, and who has paid a tax within two years, is entitled to vote. Paupers, those under guardianship and those convicted of felony, are prohibited from voting. The supreme judiciary consists of one chief justice and five associate justices. The superior court consists of a chief justice and nine associate justices. The judges of both courts are appointed by the governor, with the advice and consent of the Senate. The State is entitled to send two senators to congress and twelve members to the National House of Representatives under the federal constitution. The State house is at Boston. It is built on an eminence and its gilded dome makes a landmark for miles around. The original structure was built in 1795–1797. Since that time it has been remodeled and enlarged. A statue of Daniel Webster by the sculptor Powers, and Horace Mann, by Miss Stebbins, stand before the entrance. In the hall are famous statues of Washington, and of the most esteemed governor of late years, John A. Andrew, known as "the great war governor," who was governor from 1861-65. Every able-bodied man between eighteen and forty-five years of age may be obliged to serve in the militia. The active volunteer militia is organized in two brigades, besides two unattached corps of cadets, one of which serves as the governor's body guard.

*History.*—The shores of Massachusetts were discovered on the 15th of May, 1602, by Bartholomew Gosnold. These shores may have been and doubtless were seen before this, but the discovery of Gosnold is the first which we are able to authenticate. The Plymouth colony, leaving their native country in order to obtain a home where they might enjoy a greater religious freedom, first went to Holland, in the year 1607, and there remained until 1620, when a portion of them embarked for America. They landed at Cape Cod in November, and on December 22 made a permanent settlement in Patuxent, since called Plymouth. Another and much larger company of English Puritans settled at Salem and Charlestown in 1628 and 1629, and in Boston and Roxbury in 1630. The first settlement of Plymouth numbered one hundred and one. The principal men were William Bradford, Edward Winslow, Miles Standish, John Alden, Samuel Fuller and John Howland, to which list may be added John Carver, the first governor. William Bradford was governor from the spring of 1621 to 1657. With the settlement of Boston and vicinity in 1630, begins the history of the colony of Massachusetts bay. Winthrop, the governor of this Boston colony, and the people themselves were perfectly friendly to the Plymouth colony. The clergy, from the first settlement and for a long period after, had great influence, not only in the church, but in the civil government. Public excitement was caused throughout the colony in 1634 and 1635 on account of the opinions and conduct of Roger Williams. He made himself obnoxious to the government by denying the validity of their title to the soil, and by insisting that the Indians were its only proprietors. He was ordered to leave Massachusetts in the winter of 1635–36, and went south to a place which he called Providence. The men who first settled Plymouth and Massachusetts were friends of higher learning. In 1636 the General Court granted £400 for the support of the school at Cambridge, and in 1638 Rev. John Harvard bequeathed half of his estate, about £800, to the same seminary. It soon after received the name of Harvard College, and is now known as Harvard University. In 1641 the north line of Massachusetts was run following the Merrimac to its source, then east in such a way as to include all the northern and eastern part of New Hampshire, and a part of what is now Maine. In 1645 the General Court showed its abhorrence of the slave trade by ordering Captain Smith to send back, at his own charge, some negroes which he had brought to Pisquataqua that year. By a law passed in 1649, man-stealing was made a capital crime. The first instance of pretended witchcraft in the colony was in 1648, when a Mrs. Jones was condemned and executed. After the restoration of Charles II. the coinage of money in the colony was arrested. The coin was issued for several years, but all bore the date of 1652. About this time several towns and settlements in Maine were induced to put themselves under the jurisdiction of Massachusetts. A portion of the people were willing to become united to the government of Massachusetts, but the proceedings in the case did not escape the charge of being unjust. In 1664–5, on complaint of some of the Maine people, the commissioners of Charles II. ordered Massachusetts to relinquish its claim; but it continued its pretensions until 1691, when Maine was included in the new charter for the province. Under this same charter, known as the Provincial Charter, Plymouth colony was also annexed to Massachusetts. As early as 1637, the Indians had

begun to make war upon the colonists. The first trouble was with the Pequot tribe, living between the Connecticut river and the Thames. Massachusetts, with Connecticut, New Haven and New Plymouth, formed a union in 1643 for better defending themselves against their enemies. This confederacy was essential to their preservation in the wars with King Philip in 1675-6. It was a union which seemed almost to foreshadow the more important one formed more than a century later for the purpose of gaining independence. This spirit of self-government exhibited itself early in the history of the colony in the assumption of power under its charter; as, for instance, the right to coin money. In 1656 Cromwell meditated the plan of removing the inhabitants of New England to Ireland or Jamaica. But the people were too wise to listen to this proposal. At this time the conduct of the government of Massachusetts is justly liable to censure, for the severe treatment of the Quakers who were persecuted and banished. The Baptists were treated with almost equal severity. All this was done, notwithstanding the charter declared that there should always be liberty of conscience in matters of religion. These persecutions led to complaints to the king. Hon. Simon Bradstreet and Rev. John Norton were instructed to defend the colonists and assure the king of their loyalty. After more than half a century of struggle the king annulled the charter of the colony in 1685. Joseph Dudley was for a brief time president of a provincial council, and governed the colony. At the close of the year in which Dudley received his commission, 1685, he was succeeded by Andros, who had been governor of New York. He now received a commission to govern all the New England colonies. In the spring of 1689, the people, oppressed by the arbitrary measures of Andros, placed him in prison, and continued their old form of government. Massachusetts was then without a charter until 1692, when Maine, Plymouth and Nova Scotia were united. Sir Wm. Phipps was the first governor under this new provincial charter. He was an obscure man from Maine, near Sheepscot river. On his death, in 1694, Stoughton acted as chief magistrate.

The people of Massachusetts, with some other settlements in New England in 1679, were alarmed by menaces of war from the French. By order of Governor Stoughton the militia were prepared to defend the province, if the French should appear. The eastern Indians took advantage of the disturbed state of the country, to commit depredations and murders. In 1702 when war was declared between England and France they proved bloody allies of the French. This state of affairs continued for several years, and in 1707 an expedition was prepared to attack Port Royal in Acadie, which proved a failure. In 1708 the French and Indians attacked Haverhill and murdered many of the inhabitants. Another expedition was made in 1711 against Canada; but this expedition, like the one in 1690, was not successful. The attack of the Indians made upon Deerfield in 1704 will long be remembered as one of the deplorable events of this war.

By the treaty of Utrecht in 1713, the war with France was closed, and the Indians sought for peace with the English. As we have before stated the first newspaper in Massachusetts was called the Boston *News Letter*. It was established by Samuel Greene in 1704. A second paper was published in 1720 called the Boston *Gazette*. The third was established in 1721, called the New England *Courant*, and conducted by an older brother of the celebrated Benjamin Franklin. Meantime the colony had been growing. At the completion of a century from the first settlement of Massachusetts, its population was about 120,000. Mr. Shirley came into office, as governor of Massachusetts in 1741. Soon after this, in 1744, war again broke out between England and France. Gov. Shirley encouraged an expedition against Louisbourg, in the island of Cape Breton, which was then a rendezvous for the French fleet. The troops were commanded by Gen. Pepperrell, of Massachusetts, and the attack was in every way a successful one. Shirley also took part in the Oswego expedition of 1755, and Massachusetts encouraged and aided the expedition to Nova Scotia in the same year, which ended in the removal of the Acadians. In 1747 a riot occurred in Boston on account of the impressment of several of the citizens by a commander of a British squadron then in the harbor. The people seized some of the British officers, who were found on the shore, and it was with difficulty that the rioters were dispersed. The inhabitants of Massachusetts at this time objected to the levying of taxes for the support of the parent government, when they were not represented in the legislative body which made the laws for levying them. However, Massachusetts was never slow to send forth her citizens as soldiers when the province was in danger.

In return for this their zeal, the colonists were not accorded the privileges which they felt they deserved, and active opposition to the crown was the result. This was led by James Otis. He objected to the issuing of writs by the parent government to compel citizens to aid the revenue officers in their search for goods. "I have fully considered the subject," he said, "and I solemnly declare that I will to my dying day oppose, with all the powers God has given me, all such instruments of slavery and villainy as the writ of assistance is." Such opposition as this, to the home authority, was the beginning of the Stamp Act. When this act was put in force Massachusetts took a leading part in setting forth the right of the colonists, not to be taxed in this indirect manner without representation. In 1764 a high duty was laid on sugar and molasses. This ruined the trade of Massachusetts with the West Indies. In the fall of 1767, some troops of the Royal British artillery arrived in the harbor of Boston. The popular indignation at having royal troops thrust upon them was great. This quartering of soldiers on the Boston people, against their will, resulted in the Boston massacre in 1770. The citizens assailed the soldiers who fired upon the people in self-defense. The merchants made a combination to prevent such goods as yielded a revenue from being imported. The patriots opened communications with the other colonists by means of committees. This inter-communication of the colonists did much to strengthen their union and knit them together as one, for the great struggle which was to come. In 1774, large quantities of tea were imported into Boston from England. The consignees were desired by the people of Boston not to receive it.

When it became evident that the owners and factors of the cargoes would not comply with the request of the people, a number of men disguised as Indians, boarded the ship and threw the tea into the water. This was known as the Boston Tea Party. In return for this act England closed the port of Boston. General Gage, who for several years had been commander in chief of the British troops in America, was made governor of Massachusetts. This was another cause of irritation to the people, and they felt themselves sorely oppressed. Such men as the Adamses, Dexter, Hancock, Winthrop, Prescott, Sever, Phillips and Ward, were firm advocates of the rights of the people, but there were many who did not favor extreme measures. In 1774, just after the port of Boston was declared to be blockaded, the people assembled, and it was voted to recommend to the other colonists to refuse all commercial intercourse with England. A messenger was sent to Philadelphia to communicate the vote, and thence another was sent to Maryland and Virginia, to give information of the plan proposed in Boston. The conduct of Gage in the short space of two months fully proved that the arbitrary measures were still to be pursued, and that the voice of the representatives of the people was not to be regarded. The new Congress of Massachusetts met in February, 1775. A committee of safety, clothed with authority to call out the militia, if necessary, was appointed. They were also empowered to oppose all attempts to enforce the obnoxious laws of parliament. On the 18th of April, 1775, several British officers were on the road to Lexington and Concord to destroy the military stores of the colonists. The militia of the colony were called out, and an engagement occurred with the British troops under Lord Percy, which aroused the towns. The militia poured into Cambridge and Percy returned to Boston. The loss of the British on this occasion was nearly three hundred, of the militia eighty. It was not until July, 1775, that the Continental Congress undertook to organize the army of which George Washington was appointed commander in chief.

On June 17 occurred the battle of Bunker Hill. The Royal troops had been shut up in Boston by the superior numbers of the provincials, and this battle of Bunker Hill was brought on by the attempt of the provincial troops to gain a higher point in Charleston. When Washington was elected general in chief he stretched his lines around Boston and forced its evacuation, in March, 1776. These were the only events of the war that occurred on Massachusetts soil.

The blessings of a federal government soon became apparent, in the increased enterprise and prosperity of the country. But in no part of the United States were these advantages seen more than in Massachusetts; though at one time it seemed likely that the federal constitution would be refused by this commonwealth. It was finally adopted by a small majority. The first representatives from the state, under the new constitution, in Congress, held April, 1789, were Fisher Ames, George Partridge, George Leonard, George Thatcher, Elbridge Gerry, Benjamin Goodhue, Theodore Sedgwick and Jonathan Grant.

Massachusetts suffered under the Embargo Act of 1807, and though she opposed the war with England, in 1812-14, much of the success of the United States in naval conflicts was due to Massachusetts sailors. She was also opposed to the war with Mexico. Nevertheless Caleb Cushing led one regiment into the field.

Massachusetts has been foremost in political progress. Garrison and Phillips led the Liberty party, which was the germ of the Federal and afterward the Republican party. The old Whig party finally became merged into the Democratic party. With the change of parties Charles Sumner entered the political field. He became the most eminent statesman of his time, and was sent repeatedly by Massachusetts to the Federal Congress. The State has been largely Republican in its political principles. Massachusetts had much the same influence in bringing on the civil war that she had in bringing about the Revolutionary war. She furnished and manned many vessels for the Union navy. In 1864 it was shown that there were 22,360 Massachusetts men in the naval service. All but twelve towns furnished troops, and there were 15,000 men supplied in excess of what was called for. The total number of men in the Federal ranks was 159,165, of which number less than 1,200 were raised by draft.

Generals Knox and Lincoln were the most distinguished officers Massachusetts sent into the Revolutionary war. Out of 231,791 troops, sent by all the colonists into the field, Massachusetts furnished 67,907, the largest number furnished by any one colony. She always contributed more than her share of the money for the support of the general army. Until a constitution was adopted in 1780, Massachusetts was, during the war, under a provisional government. The first governor under the constitution was John Hancock. The prominent governors after him were Samuel Adams, 1794-97; Elbridge Gerry, 1810-12; Edward Everett, 1836-40; John A. Andrew, 1861-66. When Mr. Bowdoin was governor, during his second term of office, 1786, what is known as Shay's Rebellion took place. It was the lower class of people who were engaged in the rash enterprise, and it was undertaken on account of a confused notion of liberty.

The commonwealth spent $42,606,517 in the civil war, and about $9,000,000 was given by private contributions. Since the war ended Massachusetts has specially turned her attention to manufacturing and mechanical industries, in addition to her shipping interests, as the foreign trade which once distinguished her has gone largely to other ports. E. C. H.

MASSÉNA, ANDRÉ (1758–1817), duke of Rivoli, prince of Essling, and marshal of France, the greatest soldier and greatest general of all Napoleon's marshals, and the one man who with education and ambition might have been Napoleon's rival, was the son of a small wine merchant, it is said of Jewish origin, and was born at Nice on May 6, 1758. His parents were very poor, and he began life as a cabin boy. He did not care much for the sea, and in 1775 enlisted in the Régiment Royal Italien, a regiment of Italians in the pay of France. He quickly rose to be underofficer-adjutant; but finding his birth would prevent his ever getting a commission he left the army in 1789, retired to his native city, and married. At the sound of war

however, and the word republic, his desire to see service increased, and he once more left Italy, and joined the 3d battalion of the volunteers of the Var in 1792. In those days when men elected their officers, and nearly all the old commissioned officers were dead or had emigrated, promotion to a man with a knowledge of his drill was rapid, and by April 1793 Masséna was chef de bataillon, or colonel. His regiment was one of those in the army of General Anselme, which was ordered to occupy Nice, and his knowledge of the country, of the language, and of the people was so useful that in December he was already general of division. In command of the advanced guard he won the battle of Saorgio in August 1794, capturing ninety guns, and after many successes he at last, on November 23, 1795, with the right wing of the army of Italy, won the great victory of Loano, in which four thousand Austrians and Sardinians were put hors de combat. In Bonaparte's great campaigns of 1796 and 1797 Masséna was his most trusted general of division; in each battle he won fresh laurels, until the crowning victory of Rivoli, from which he afterwards took his title. It was during this campaign that Bonaparte gave him the title of *enfant chéri de la victoire*, which he was to justify till he met the English in 1810. Masséna's next important service was in command of the army in Switzerland, which united the army in Germany under Moreau, and that in Italy under Joubert. There he proved himself a great general; the archduke Charles and Suwaroff had each been successful in Germany and in Italy, and now turned upon Masséna in Switzerland. That general held his ground well against the archduke, and then suddenly, leaving Soult to face the Austrians, he transported his army to Zürich, where, on September 26, 1799, he entirely defeated Suwaroff, taking two hundred guns and five thousand prisoners. His campaign and battle placed his reputation on a level with that of his compatriot Bonaparte, and he might have made the revolution of Brumaire, but he was sincerely attached to the republic, and had no ambition beyond a desire to live well and have plenty of money to spend. Bonaparte, now first consul, sent him to Genoa to command the débris of the army of Italy, and he nobly defended Genoa from February to June to the very last extremity, giving time for Bonaparte to strike his great blow at Marengo. He now went to Paris, where he sat in the Corps Législatif in 1803, and defended Moreau, but where Napoleon took his measure, and did not interfere with him. In 1804 he was made one of the first marshals of France of the new régime, and in 1805 was decorated with the Grand Eagle of the Legion of Honour. In that year Napoleon needed an able general to keep in check the archduke Charles in Italy, while he advanced through Germany with the grand army. Masséna was chosen; he kept the archduke occupied till he got news of the surrender of Ulm, and then on October 30th utterly defeated him in the battle of Caldiero. After the peace of Pressburg had been signed, Masséna was ordered to take possession of the kingdom of Naples, and to place Joseph Bonaparte on the throne. This task done, Napoleon summoned Masséna to Poland, where he as usual distinguished himself, and where he for the time gave up his republican principles, and was made duke of Rivoli. In the campaign of 1809 he covered himself with glory at Landshut and at Eckmühl, and finally at the little village of Essling, which he held with such determination that Napoleon had some right to call his otherwise complete defeat of Aspern a victory. When the retreat to the island of Lobau was ordered, it was Masséna who covered the broken regiments, and held the *tête du pont*; and on the field of Wagram it was Masséna who, though too ill to ride, directed from his carriage the movements of the right wing, and recovered the honour of France. For his great services he was created prince of Essling, and given the princely castle of Thouars. He was then ordered to Spain to "drive the English into the sea." The campaigns of 1810 and 1811, the advance to and the retreat from Torres Vedras, are well known from Napier's history, who does full justice to Wellington's great opponent. Masséna himself ascribed his failure to the frequent disobedience of his three subordinate generals Ney, Reynier, and Junot, and with some justice; but he alone could have stayed so long before the lines, and could have made the long halt at Santarem, which checked Wellington so thoroughly. The retreat was as finely conducted as the advance, and would have been even more triumphant had Ney obeyed orders. Even then he was again ready to try his fortune, and nearly defeated Wellington at Fuentes d'Oñoro, though much hampered by Bessières. Recalled with ignominy, his prestige gone, the old marshal felt he had a right to complain of Ney and of Napoleon himself, and, it is said, opened communications with Fouché, and the remnant of the republican party. Whether this be true or not, Napoleon gave his greatest marshal no more employment in the field, but made him merely commandant of the 8th military division, with his headquarters at Marseilles. This command he still held at the restoration of the Bourbons, when Louis XVIII. confirmed him in it, and gave him letters of naturalization, as if the great leader of the French armies had not ceased to be an Italian. When Napoleon returned from Elba, Masséna, probably by the advice of Fouché, kept Marseilles quiet to await events, the greatest service he could do the royalists, but afterwards imputed to him as a fault. After the second restoration Masséna was summoned to sit on the court martial which tried Marshal Ney, but, though he had been on bad terms with that general, and attributed his own disgrace to him, the old soldier would not be his comrade's judge. This refusal was used by the royalists to cruelly attack the marshal, against whom they raked up every offence they could think of, and whose victories they forgot. This annoyance shortened his life, and on the 4th April 1817 the old hero died. He was buried in Père-la-Chaise, with only the word "Masséna" upon his tombstone.

In private life indolent, greedy, rapacious, ill-educated, morose, on the field of battle Masséna was a man of genius, prompt in resource, indefatigable, perfectly brave, and never knowing when he was beaten. Italian he always was in his indolence, but in his quickness of resource a real compatriot of Napoleon himself.

See Thiébault's *Éloge funèbre*, and Koch's *Mémoires de Masséna*, 4 vols., 1849, a most valuable work, and most carefully compiled. See also the military histories of the epoch, but in reading Napier's pictures of him and Soult it is well to remember that author's personal friendship with the latter.

MASSILLON, a city of the United States, in Stark county, Ohio, is situated on the Tuscarawas, a head stream of the Muskingum, communicates with Lake Erie by the Ohio canal, and forms an important junction for various lines of railway. It is well known for its coal-mines and white sandstone quarries; and it also contains blast furnaces, rolling mills, foundries, machine-shops, grist mills, and extensive establishments for the manufacture of agricultural implements, glass, and paper. The population, 3819 in 1860, was 6838 in 1880.

MASSILLON, Jean Baptiste, was born at Hyères on June 24, 1663, and died at Clermont on September 28, 1742. He was thus, except Saint-Simon and Fontenelle, the longest-lived of the men of the Siècle de Louis Quatorze. It is noteworthy that, like the majority of the great pulpit orators of his own and the preceding generation, he was a southerner. His father, François Massillon, was a notary, and he appears to have been well educated. In 1681 he joined the congregation of the Oratory, which at that time had a high reputation. But, although he had thus chosen

an order where the rules were by no means strict, he was not anxious for easy living or secular renown. The credit which he received for his first efforts at preaching startled him, and he sought a much more severe discipline, one indeed which is said to have been of Trappist rigour. Accident, however, made his literary and oratorical talents known to the Cardinal de Noailles, who determined that the church should not lose so well qualified a defender. In obedience to the cardinal, Massillon left the abbey of Septfonds, rejoined the Oratory, and was introduced to the Parisian seminary of Saint Magloire in 1696. He was soon set to work to preach in the Paris churches, and his reputation spread rapidly from city to court. He preached before Louis XIV. for the first time in Advent 1699. He made a profound impression, and it is reported that his generous elder, Bourdaloue, from whom Massillon himself had learnt much, said of him, "He must increase, but I must decrease." His fame, however, did not lead to immediate preferment. In the first place, the Oratorians were on bad terms with the Jesuits, and were considered too liberal to suit the reign of gloomy pietism and severe orthodoxy in which Louis's dissolute life closed. In the second, Massillon was neither a flatterer, nor did he resort to the abrupt denunciation of vice which had succeeded in the case of some of his predecessors. Indeed, in the last years of the reign there was nothing (so far as the king was concerned) to denounce, unless it were an excess of orthodoxy. Louis's famous saying that other preachers made him pleased with them, but that Massillon made him displeased with himself, may have been merely a *mot*, but it may also have expressed an involuntary truth. However this may be, Massillon, who perhaps desired no office, received none as long as the old king lived. The regency was much more favourable to him, and in 1717 he was nominated to the see of Clermont, with the additional honour of being commissioned to preach the next year's *Petit Carême* or series of short Lent sermons before the young Louis XV. Bishop in 1717, Lent preacher in 1718, Massillon received in 1719 a yet further honour, though this time a secular one, by being elected to the Academy. Various causes, however, combined to remove him from Paris. His own standard of duty was high, and he was not likely in any case to have acquiesced in the position of a non-resident bishop; the court grew more and more dissolute; and his advance in years must have somewhat disqualified him from preaching and travelling. He delivered but few sermons in Paris after the *Petit Carême*, and preached there for the last time in 1723, when he pronounced the funeral oration of the duchess-dowager of Orleans. The twenty years of life which remained to him were spent at Clermont, where he was distinguished for all good works, especially for exacting the minimum of episcopal dues and expending the maximum on charity.

Massillon's works are made up for the most part of sermons, lectures, synodal addresses, and the like. They have been repeatedly edited, and are easily accessible in two large volumes published by Didot. As a pulpit orator, if not as a theologian, Massillon probably deserves the highest rank among Frenchmen. His style is very nearly perfect, uniting the polish of the later age of Louis XIV. with the vigour of the earlier. His thoughts are original and just, and the arrangement of his discourses lucid and orderly without being unduly scholastic. He has usually been contrasted with his predecessor Bourdaloue, the latter having the credit of vigorous denunciation, Massillon of gentle persuasiveness. But few preachers can have excelled him in vigour when he chose to be stern. Besides the *Petit Carême*, his sermons on the Prodigal Son, on Death, for Christmas Day, for the Fourth Sunday in Advent, may be cited as perhaps his masterpieces. But in truth Massillon is singularly free from inequality. His great literary power, his reputation for benevolence, and his known toleration and dislike of doctrinal disputes caused him to be much more favourably regarded than most churchmen by the *philosophes* of the 18th century. He acquired the surname of the Racine of the pulpit, but extreme purity of style is almost the only point of contact between the two writers.

MASSINGER, Philip (1584–1640), one of the most prolific, scholarly, and powerful dramatists among the immediate successors of Shakespeare. He was born in 1584, went to Oxford (St Alban's Hall) in 1602, and left in 1606. This is all that is known of his early life, except that his father, as appears from the dedication of one of his plays (*The Bondman*), was in the service of the Herberts. That his father's service was not menial is proved by his having once been the bearer of letters from the earl of Pembroke to the queen. The industry of antiquaries has discovered only one little fact about Massinger between his leaving Oxford in 1606 and his having a comedy performed at court in 1621. This fact is that he joined with two dramatists, Field and Daborne, in asking an advance of £5 from the theatrical capitalist, Henslowe. This painful request, the date of which is conjectured to be about 1614, sets forth that the three petitioners were "in unfortunate extremitie." In his part of the document Massinger says that he has "ever found" Henslowe "a true loving friend." The expression seems to point to his having been connected with plays and players for some considerable time. After 1621 many of his plays were acted and published; but from the tone of his dedications it is to be inferred that he was often in straits. The entry in the parish register of St Saviour's—"March 20, 1639–40—buried Philip Massinger, a stranger"—may mean only that Massinger was not a resident in the parish; but it is sadly out of keeping with the dramatist's place in the respect of posterity.

In the barrenness of authentic fact, conjecture has been busy with Massinger's life and character. One of the questions that have been raised about him,—whether or not he was a Roman Catholic,—leads to other questions that have more than a personal interest. Attempts to fix the political or the religious creed of a dramatist are generally fanciful; as a rule, when a critic finds an opinion expressed by one of a dramatist's personages with exceptional and striking force, he jumps to the conclusion that the dramatist must have held this opinion himself as a ruling conviction. The evidence that Massinger was a Roman Catholic at a time when the creed was held under pains and penalties is of a more serious kind, though not conclusive. It rests upon three of his plays, *The Virgin Martyr* (printed in 1622, acted before 1620), *The Renegado* (acted in 1624), and *The Maid of Honour* (printed in 1632, but probably acted earlier). In the first of these Massinger was assisted by Dekker. Whether or not the author was a Roman Catholic, it is certain that only a Roman Catholic audience could be expected to enter into the spirit of these plays and applaud at the end; and they are very remarkable theatrical phenomena to have appeared in the reign of James.

The *Virgin Martyr*, founded on the martyrdom of Dorothea in the time of Diocletian, is, in effect, an old miracle play in five acts. The devil himself appears on the stage,—first in human shape as the servant of a persecutor, hunting out victims and instigating the most cruel tortures; afterwards in "a fearful shape" with fire flashing round him. The page of the martyr Dorothea is an angel in disguise, who also appears in his own proper shape before the end of the play. Dorothea is tortured on the stage in the most revolting fashion, dragged about by the hair, kicked, beaten with cudgels, but her page Angelo stands by, and she is miraculously preserved from hurt. Other miracles are performed on the stage. A persecutor falls down in a fit when about to proceed to subject the martyr's constancy to the foulest trials. In the last act a basket of fruit from paradise is brought on, and the chief persecutor eating of it is wholly changed in spirit, and drives away his diabolic servant by holding up a cross of flowers. At the close the martyrs appear in white robes, transfigured. The *Virgin Martyr* further resembles the miracle play in the coarseness of the comic scenes intended to illustrate the power of the devil over the most base and grovelling natures. The tone of the play throughout is serious and lofty; the passions of the persecutors and the heroic devotion of the martyrs are given with great dramatic force. This is a very

remarkable play to have appeared suddenly amidst the run of secular pieces. It seems to have been popular, and was several times reprinted before the Restoration. That the *Renegado* should have found favour is still more remarkable. In itself it is a powerfully constructed play, strong in character and incident. Massinger's leaning to Roman doctrine is supposed to be shown by his making one of his heroines—a converted Turk, a sultan's sister—experience complete spiritual transformation after receiving the rite of baptism. But there is a more suggestive and stranger fact than this. The hero of the piece, Francisco, is a Jesuit priest, treated with profound respect throughout, a man of noble unselfish aims, running all risks to save and gain souls, exercising the strongest moral influence for the wisest and most benevolent purposes. Francisco's influence pervades the play, and is crowned with triumph at the end. He sails back to Venice with a noble lady rescued from the infidel, her virtue protected by an amulet during her captivity, a renegade military hero restored to his country and the church, a noble Venetian rescued from spiritual and physical perils, the beautiful sister of the sultan converted to Christianity. That a London audience should have tolerated this glorification of a Jesuit within twenty years of the Gunpowder Plot is an extraordinary fact, of which the explanation is still to seek. In the *Maid of Honour* the heroine relieves a highly complicated situation at the end by taking the veil, giving a third of her property to a nunnery, a third for pious uses, and a third to an honest, faithful, but to her unattractive lover. For this she is held up as "to all posterity a fair example for noble maids to imitate." Only an audience of very pious Catholics could have sympathized with such a conclusion

Such plays show that Massinger, if not a Roman Catholic, was at least not blinded by the popular hatred of them, but could dwell in rapt admiration on what was noble and lofty in the motives supplied by the Roman Church. The strange thing is that he found a manager to produce these plays, or an audience to tolerate them. It may be doubted whether Massinger was ever a popular dramatist. His poverty is not indeed conclusive on this point, for the prices paid for plays were so small that a dramatist could hardly make a livelihood by play writing, unless he was also an actor or a theatrical manager. But the best qualities of his plays appeal rather to thoughtful politicians, moralists, and students of character than to the simple feelings of the ordinary playgoer. Only one of them, *A New Way to Pay Old Debts* (printed 1633), has kept the stage, and that chiefly because the leading character, Sir Giles Overreach, a sort of commercial Richard III., a compound of "the lion and the fox," provides many opportunities for a great actor. Like all Massinger's plays, it is most ingenious and effective in construction, but in this as in others he has been more intent upon the elaboration of a plot and the exhibition of a ruling passion than upon winning the love and admiration of his audience for heroes and heroines. The other personages besides Sir Giles are either conventional comic figures, or dim, feebly outlined, uninteresting characters. The reformed prodigal and the two pairs of lovers who outwit the cunning diplomatist by simple means seem poor, joyless, bloodless phantoms when put side by side with the rich life of Shakespeare's youthful lovers and reckless scapegraces; they are mere foils to Overreach; their life is not displayed, it is only indicated in the dialogue. With the exception of this play, all Massinger's have been relegated to the study since his own time. The *Fatal Dowry*] (printed 1632), in which Massinger had the assistance of Field, was partially resuscitated by Rowe, being made the basis of the *Fair Penitent*. In Massinger's own judgment, the *Roman Actor* was "the most perfect birth of his Minerva." It is in effect a study of the tyrant Domitian, and of the results of despotic rule on the despot himself and his court; the intrigues and counter intrigues, the rise of sycophancy, the fall of honesty, the growth of the appetite for blood, the growth and final triumph of the spirit of revenge, are exhibited with great power. Among the dramatists of that great period, Massinger comes next to Shakespeare in the art of opening and developing a plot. The *Bondman*, the *Duke of Milan*, and the *Great Duke of Florence* are also favourable specimens of Massinger's power. But what was said by one of his admirers in the dedication of the *City Madam* is perfectly true, that, "though he composed many plays, he wrote none amiss." The manners and the characters are always clearly conceived, although the dramatist's strength is put forth in the portrayal of some one ruling passion. The action always marches forward steadily, with as little as possible of irrelevant digression; so steadily in fact is the main purpose pursued as to produce a certain air of labour and constraint. The language is never mean, and never turgid; in impassioned situations it wants fire and directness. If the stage were ever deliberately employed as an historical school, frequented by audiences anxious to get a clear and vivid impression of important situations, going to the theatre not to be interested against their will but willing to be interested, the dramas of Massinger would furnish excellent models.

Several of Massinger's plays are no longer extant. Eight of them were among those destroyed by Warburton's cook. The most recent edition of those remaining, nineteen in number, is Cunningham's (1870). Gifford edited Massinger with great care. (W. M.)

MASSORAH (מָסוֹרָה), better MASSORETH (מָסֹרֶת), a late Hebrew word meaning "tradition," is the technical term specially applied to the tradition by which Jewish scholars (Massorets, בַּעֲלֵי הַמָּסֹרֶת) sought to fix the correct writing and reading of the text of the Old Testament. An oral tradition on disputed points of this sort naturally existed from the early days of the Jewish schools, but the use of a written Massorah in notes on the margin of Bibles, at the end of Biblical codices or of the individual books contained in them, or in separate works appears to have followed the introduction of the vowel points, and to have been influenced by similar labours of Syrian scholars. See HEBREW LANGUAGE, vol. xi. p. 600

MASSOWAH, or MESOWAH, a town on the Abyssinian coast of the Red Sea, on a small coral island of the same name, in 15° 30′ N. lat. and 39° 30′ E. long. The height of the island is from 20 to 25 feet above the sea, the length does not exceed ½ mile, and the breadth is about ¼ mile. The western half is occupied by the town; in the eastern half are Mohammedan burying-grounds and dismantled cisterns. Most of the dwelling-houses are mere straw huts; the mosque, the Roman Catholic church, the Government buildings and custom-house, and the residences of the principal merchants are of stone. Water was formerly scarce, and had for the most part to be carried from the mainland; but in 1872 an ancient aqueduct from Mokullu was restored, and continued by an embankment to the town. Besides the original Ethiopians, who speak a Tigré dialect corrupted with Arabic, the population, estimated at from 5000 to 6000, comprises Arabs from Yemen and Hadramaut, Gallas and Somalis, and Hindus from Surat. The trade, which consists mainly in exporting hides, butter, Abyssinian coffee, and civet, and importing European and Indian cotton goods and silks, increased in value from about £65,000 per annum in 1865 to from £240,000 to £280,000 between 1879 and 1881.

The island of Massowah (locally Base) has probably been inhabited from a very early date. It was at Massowah (Matzua, as they called it) that the Portuguese landed in 1542 under Christovão da Gama. Captured by the Turks in 1557, the island has remained more or less strictly a Turkish possession ever since. A military colony of Bosnians settled at Arkiko was appointed, not only to defend it in case of attack from the mainland, but to keep it supplied with water in return for $1400 per month from the town's customs. For some time in the close of last century Massowah was held by the sherif of Mecca, and it afterwards passed under Mehemet Ali of Egypt. The Turks were reinstated about 1850, but in 1865 they handed the island back to Egypt for an annual tribute of 2½ million piastres.

See *Bruce's Travels*, vol. iv.; Heuglin in Petermann's *Mittheilungen*, 1860; Rassam, *Brit. Mission to Abyssinia*, 1869; Pennazzi in *Nuova Antologia*, July 1880.

MASSYS, or MATSYS, QUINTIN (1466–1530), was born at Louvain, where he first learned a mechanical art. During the greater part of the 15th century the centres in which the painters of the Low Countries most congregated were Bruges, Ghent, and Brussels. Towards the close of the same period Louvain took a prominent part in giving employment to workmen of every craft. It was not till the opening of the 16th century that Antwerp usurped the lead which it afterwards maintained against Bruges and Ghent, Brussels, Mechlin, and Louvain. Quintin Massys was one of the first men of any note who gave repute to the guild of Antwerp. A legend still current relates how the smith of Louvain was induced by affection for the daughter of an artist to change his trade and acquire proficiency in painting. A less poetic but perhaps more real version of the story tells that Quintin had a brother with whom he was brought up by his father Josse Massys, a smith, who held the lucrative offices of clockmaker and architect to the municipality of Louvain. It came to be a question which of the sons should follow the paternal business, and which carve out a new profession for himself. Josse the son elected to succeed his father, and Quintin then gave himself to the study of painting. But it is not improbable that as he lived in an age when single individuals were cunning in various branches of design, Quintin was equally familiar with the chisel and file or the brush and pencil. We are not told expressly from whom Quintin learned the profession in which he acquired repute, but his style seems necessarily derived from the lessons of Dierick Bouts, who took to Louvain the mixed art of Memling and Van der Weyden. When he settled at Antwerp, at the age of twenty-five, he probably had a style with an impress of its own, which certainly contributed most importantly to the revival of Flemish art on the lines of Van Eyck and Van der Weyden. What particularly characterizes Quintin Massys is the strong religious feeling which he inherited from earlier schools. But that again was permeated by realism which frequently degenerated into the grotesque. Nor would it be too much to say that the facial peculiarities of the boors of Van Steen or Ostade have their counterparts in the pictures of Massys, who was not, however, trained to use them in the same homely way. From Van der Weyden's example we may trace the dryness of outline and shadeless modelling and the pitiless finish even of trivial detail, from the Van Eycks and Memling through Dierick Bouts the superior glow and richness of transparent pigments, which mark the pictures of Massys. The date of his retirement from Louvain is 1491, when he became a master in the guild of painters at Antwerp. His most celebrated picture is that which he executed in 1508 for the joiners' company in the cathedral of his adopted city. Next in importance to that is the Maries of Scripture round the Virgin and Child, which was ordered for a chapel in the cathedral of Louvain. Both altar-pieces are now in public museums, one at Antwerp, the other at Brussels. Both challenge attention for the qualities which have already been described. They display great earnestness in expression, great minuteness of finish, and a general absence of effect by light or shade. As in early Flemish pictures, so in those of Massys, superfluous care is lavished on jewellery, edgings, and ornament. To the great defect of want of atmosphere such faults may be added as affectation, the result of excessive straining after tenderness in women, or common gesture and grimace suggested by a wish to render pictorially the brutality of jailers and executioners. Yet in every instance an effort is manifest to develop and express individual character. This tendency in Massys is chiefly illustrated in his pictures of male and female market bankers (Louvre and Windsor), in which an attempt is made to display concentrated cupidity and avarice. The other tendency to excessive emphasis of tenderness may be seen in two replicas of the Virgin and Child at Berlin and Amsterdam, where the ecstatic kiss of the mother is quite unreal. But in these examples there is a remarkable glow of colour which takes us past many defects. Expression of despair is strongly exaggerated in a Lucretia at the museum of Vienna. On the whole the best pictures of Massys are the quietest; his Virgin and Christ or Ecce Homo and Mater Dolorosa (London and Antwerp) display as much serenity and dignity as seems consistent with the master's art. A telling example of his partiality for grotesque character in face is an Epiphany in the collection of Mr H. R. Hughes in England. His skill as a portrait painter has not been sufficiently admired, probably because most of his likenesses have ceased to be identified with his name. Egidius at Longford, which drew from Sir Thomas More a eulogy in Latin verse, is but one of a numerous class, to which we may add the portrait of Maximilian of Austria in the gallery of Amsterdam, a masterpiece which at some future period may afford a clue to other works of similar treatment in English and Continental galleries. Massys in this branch of practice was much under the influence of his contemporaries Lucas of Leyden and Mabuse. His tendency to polish and smoothness excluded to some extent the subtlety of modulation remarkable in Holbein and Dürer. There is reason to think that he was well acquainted with both these German masters. He probably met Holbein more than once on his way to England. He saw Dürer at Antwerp in 1520. Quintin died at Antwerp in 1530. The puritan feeling which slumbered in him was fatal to some of his relatives. His sister Catherine and her husband suffered at Louvain in 1543 for the then capital offence of reading the Bible, he being decapitated, she buried alive in the square fronting the cathedral.

Quintin's son, Jan Massys, inherited the art but not the skill of his parent. The earliest of his works, a St Jerome, dated 1537, in the gallery of Vienna, the latest, a Healing of Tobias, of 1564, in the museum of Antwerp, are sufficient evidence of his tendency to substitute imitation for original thought.

MASTER AND SERVANT. These are scarcely to be considered as technical terms in law. The relationship which they imply is created when one man hires the labour of another for a term. Thus it is not constituted by merely contracting with another for the performance of a definite work, or by sending an article to an artificer to be repaired, or engaging a builder to construct a house. Nor would the employment of a man for one definite act of personal service—*e.g.*, the engagement of a messenger for a single occasion—generally make the one master and the other servant. It was held, however, in relation to the offence of embezzlement, that a drover employed on one occasion to drive cattle home from market was a servant within the statute. (See article EMBEZZLEMENT for definition of "clerk" or "servant" in that connexion.) On the other hand, there are many decisions limiting the meaning of "servants" under wills giving legacies to the class of servants generally. Thus "a person who was not obliged to give his whole time to the master, but was yet in some sense a servant," was held not entitled to share in a legacy to the servants. These cases are, however, interpretations of wills where the intention obviously is to benefit domestic servants only. And so in other connexions questions may arise as to the exact nature of the relations between the parties—whether they are master and servant, or principal and agent, or landlord and tenant, or partners, &c.

The terms of the contract of service are for the most part such as the parties choose to make them, but in the absence of express stipulations terms will be implied by the law. Thus, "where no time is limited either expressly or by implication for the duration of a contract of hiring and

service, the hiring is considered as a general hiring, and in point of law a hiring for a year." But "in the case of domestic and menial servants there is a well-known rule, founded solely on custom, that their contract of service may be determined at any time by giving a month's warning or paying a month's wages, but a domestic or other yearly servant, *wrongfully* quitting his master's service, forfeits all claim to wages for that part of the current year during which he has served, and cannot claim the sum to which his wages would have amounted had he kept his contract, merely deducting therefrom one month's wages. Domestic servants have a right by custom to leave their situations at any time on payment of a calendar month's wages in advance, just as a master may discharge them in a similar manner" (Manley Smith's *Law of Master and Servant*, chaps. ii. and iii.). The master's right to chastise a servant for dereliction of duty (which appears to be still recognized in some American cases) is no longer sustained in English law, unless perhaps in the case of servants under age, to whom the master stands *in loco parentis*.

The following are assigned by Manley Smith as in general sufficient grounds for discharging a servant:—(1) wilful disobedience of any lawful order; (2) gross moral misconduct; (3) habitual negligence; (4) incompetence or permanent disability caused by illness.

A master has a right of action against any person who deprives him of the services of his servant, by enticing him away, harbouring or detaining him after notice, confining or disabling him, or by seducing his female servant. Indeed the ordinary and only available action for seduction in English law is in form a claim by a parent for the loss of his daughter's services.

The death of either master or servant in general puts an end to the contract. A servant wrongfully discharged may either treat the contract as rescinded and sue for services actually rendered, or he may bring a special action for damages for the breach. A master is bound to provide food (but apparently not medical attendance) for a servant living under his roof, and wilful breach of duty in that respect is a misdemeanour under 24 & 25 Vict. c. 100.

A servant has no right to demand "a character" from an employer, and if a character be given it will be deemed a privileged communication, so that the master will not be liable thereon to the servant unless it be false and malicious. A master by knowingly giving a false character of a servant to an intending employer may render himself liable—should the servant for example rob or injure his new master.

For penalties incurred by personating masters and giving false certificates of character, or by persons offering themselves as servants with false or forged certificates, see 32 Geo. III. c. 56.

Reference may be made to the article on LABOUR AND LABOUR LAWS for the cases in which special terms have been introduced into contracts of service by statute (*e.g.*, Truck Act), and for the recent legislation on the subject generally, including the Employers' Liability Act, 1880.

The master's liability on the contracts of his servant depends on altogether different principles from those on which his liability for negligence has been justified. It is substantially a case of liability as principal for the acts of an agent. The main question in all cases is whether the alleged agent had authority to make a contract for his principal, and in the relation of master and servant there may be any variety of circumstances giving rise to that presumption. Here the rights of third persons have to be considered, and the master will be held liable to them wherever he has "by words, conduct, or demeanour held out his servant as a general agent, whether in all kinds of business or in transacting business of a particular kind,"—even if the servant should act contrary to express orders. For example, a horse-dealer sending his servant to market with a horse to sell will be liable on the servant's warranty, although he has been positively ordered not to warrant; whereas an owner sending a stranger to sell would not be liable on a warranty given contrary to express directions.

MASTIC, or MASTICH, a resinous exudation obtained from the lentisk, *Pistacia Lentiscus*, an evergreen shrub of the natural order *Anacardiaceæ*. The lentisk or mastic plant is indigenous to the Mediterranean coast region from Syria to Spain, but grows also in Portugal, Morocco, and the Canaries. Although experiments have proved that excellent mastic might be obtained in other islands in the archipelago, the production of the drug has been, since the time of Dioscorides, almost exclusively confined to the island of Scio. The mastic districts of that island are for the most part flat and stony, with little hills and few streams. The shrubs are about 6 feet high. The resin is contained in the bark and not in the wood, and in order to obtain it numerous vertical incisions are made, during June, July, and August, in the stem and chief branches. The resin speedily exudes and hardens into roundish or oval tears, which are collected, after about fifteen days, by women and children, in little baskets lined with white paper or cotton wool. The ground around the trees is kept hard and clean, and flat pieces of stone are often laid beneath them to prevent any droppings of resin from becoming contaminated with dirt. The collection is repeated three or four times between June and September, a fine tree being found to yield about 8 or 10 lb of mastic during the season. Besides that obtained from the incisions, mastic of very fine quality spontaneously exudes from the small branches. The harvest is affected by showers of rain during the period of collection, and the trees are much injured by frost, which is, however, of rare occurrence in the districts where they grow.

Four qualities of mastic are recognized by the dealers in Scio.

1. *Cake*, consisting of large pieces, sold chiefly for use in the seraglios, being chewed by women of all ranks throughout the Turkish empire, for the purpose of imparting an agreeable odour to the breath. This quality is worth 120 to 130 piastres per oke (of 2·83 lb) or even more.
2. *Large tears*, worth 90 to 100 piastres.
3. *Small tears*, valued at 75 to 80 piastres.
4. Mastic mixed with fragments of leaves and sand, chiefly consumed in the manufacture of the Turkish liqueur, or mastic brandy, called *raki*, and other cordials.

The third sort, in small tears, is that which is chiefly exported to England, the first and second qualities being sent to Turkey, especially Constantinople, also to Trieste, Vienna, and Marseilles.

These varieties are known to the dealers as κυλιστό, φλισκάρι, πῆττα, and φλοῦδα respectively.

Mastic still forms the principal revenue of Scio. In 1871, 28,000 lb of picked and 42,000 lb of common were exported from that island, the former being worth 6s. 10d. and the latter 2s. 10d. per lb. The average price in London varies from 2s. 6d. to 4s. 6d. per lb.

During the 15th, 16th, and 17th centuries mastic enjoyed a high reputation as a medicine, and formed an ingredient in a large number of medical compounds, but its use in medicine is now almost obsolete.

Mastic occurs in English commerce in the form of roundish tears about the size of peas, some of them, however, being oblong or pear-shaped. They are transparent, with a glassy fracture, of a pale yellow or faint greenish tinge, which darkens slowly by age. When chewed they rapidly soften, by which character they are easily distinguished from Sandarac resin, which while bearing a strong resemblance to mastic occurs in tears of a more cylindrical shape. The mastic which has been imported of late years presents a bright glassy appearance from having been washed free from dust.

Mastic is soluble in turpentine, chloroform, ether, acetone, and oil of cloves; but cold alcohol dissolves only 90 per cent. of it. The soluble portion is called *Alpha resin* ($C^{20}H^{32}O^3$), and possesses acid properties. The insoluble portion, *Beta resin* or *Masticin*, is somewhat less rich in oxygen, and is a translucent colourless tough substance insoluble in caustic alkali.

*Pistacia Khinjuk*, Stocks, and *P. cabulica*, St., trees growing throughout Sindh, Baluchistan, and Cabul, yield a kind of mastic which is met with in the Indian bazaars under the name of *Mustagirámí, i.e.*, Roman mastic. This when met with in the European market is known as East Indian or Bombay mastic. In Algeria *P. atlantica*, Desf., yields a solid resin, which is collected and used by the Arabs as a masticatory. Cape mastic, used by the colonists, but not exported to England, is the produce of *Euryops multifidus*, the resin bush, or *harpuis bosch*, of the Boers,—a plant of the composite order growing abundantly in the Clanwilliam district. Dammar resin is sometimes sold under the name of mastic. The West Indian mastic tree is the *Bursera gummifera*, and the Peruvian mastic is *Schinus Molle*; but neither of these furnishes commercial resins.

MASTODON (from μαστός, "nipple," and ὀδούς, "tooth"), a name, suggested by the conical or papillary form of the projections on the molar teeth of some of the species, given by Cuvier to a genus of extinct elephant-like animals. Their position in the suborder *Proboscidea* of the great order *Ungulata* has been indicated in the article MAMMALIA (p. 425 of the present volume).

In size, general form, and principal osteological characters the Mastodons resembled the Elephants. It is by the teeth alone that the two groups are to be distinguished, and, as shown in the article just referred to, so numerous are the modifications of these organs in each, and so insensibly do they pass by a series of gradations into one another, that the distinction between the two is an arbitrary and artificial one, though convenient and even necessary for descriptive purposes.

As in other Proboscideans, the teeth of Mastodons consist only of incisors and molars. The incisors or tusks are never more than a single pair in each jaw. In the upper jaw they are always present and of large size, but apparently never so much curved as in some species of Elephant, and they often have longitudinal bands of enamel, more or less spirally disposed upon their surface, which are not met with in Elephants. Lower incisors, never found in true Elephants, are present throughout life in some species of Mastodon, which have the symphysis of the lower jaw greatly elongated to support them (as in *M. angustidens*, *M. pentelici*, and *M. longirostris* (see fig. 1, *C*). In the common American species (*M. ohioticus*, Blumenbach) there were two tusks in the lower jaw in the young of both sexes; these were soon shed in the female, but one of them was retained in the male. In other species no inferior tusks have been found, at all events in adult life (see figure of *M. turicensis*).

The molar teeth are six in number on each side, increasing in size from before backwards, and, as in the Elephants, with a horizontal succession, the anterior teeth being lost before the full development of the posterior teeth, which gradually move forward, taking the place of those that have been destroyed by wear. This process is, however, not so complete as in the true Elephants, and as many as three teeth may be in place in each jaw at one time. There is, moreover, in many species a true vertical succession, affecting either the third, or the third and second, or (in one American species, *M. productus*) the first, second, and third of the six molariform teeth. These three

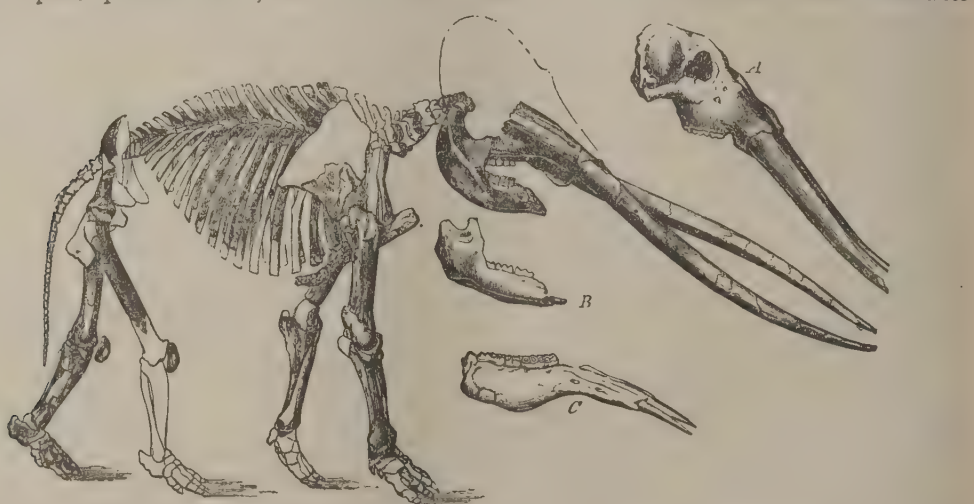

FIG. 1.—*Mastodon turicensis* (Pliocene). From Sismonda. A, B, *M. ohioticus*; C, *M. longirostris*.

are therefore reckoned as milk molars, and their successors as premolars, while the last three, which are never changed, correspond to the true molars of those animals in which the typical dentition is fully developed. The study of the mode of succession of the teeth in the different species of Mastodons is particularly interesting, as it exhibits so many stages of the process by which the very anomalous dentition of the modern Elephants may have been derived by gradual modification from the typical heterodont and diphyodont dentition of the ordinary Mammal. It also shows that the anterior molars of Elephants do not correspond to the premolars of other Ungulates, but to the milk molars, the early loss of which in consequence of the peculiar process of horizontal forward-moving succession does not require, or allow time for, their replacement by premolars. It must be noted, however, that, in the Mastodon in some respects the least specialized in tooth-structure, the *M. ohioticus* of North America, no vertical succession of the molars has yet been observed, although vast numbers of specimens have been examined.

The Mastodons have, generally speaking, fewer ridges on their molar teeth than the Elephants; the ridges are also less elevated, wider apart, have a thicker enamel covering, and scarcely any cementum filling up the space between them. Sometimes (as in *M. ohioticus*) the ridges are simple transverse wedge-shaped elevations with straight or

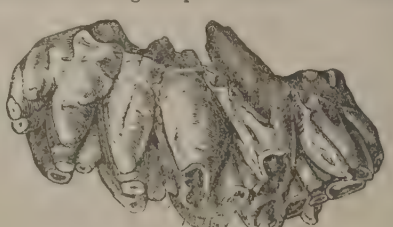

FIG. 2.—Upper Molar of *Mastodon arvernensis*. From Owen.

concave edges. In other species the summits of the ridges are more or less subdivided into conical cusps, and may have accessory cusps clustering around them (as in *M. arvernensis*, see fig. 2). When the apices of these are worn by mastication, their surfaces resemble circles of dentine,

surrounded by a border of enamel, and as the attrition proceeds different patterns are produced by the union of the bases of the cusps, a trilobed or trefoil form being characteristic of some species.

Certain of the molar teeth of the middle of the series in both Elephants and Mastodons have the same number of principal ridges, and those in front of them have fewer and those behind a greater number. These teeth were distinguished as "intermediate" molars by Dr Falconer, to whose extensive and conscientious researches we owe much of our knowledge of the structure of this group of animals. In the restricted genus *Elephas* there are only two, the last milk molar and the first true molar (or the third and fourth of the whole series), which are alike in the number of ridges; whereas in the Mastodons there are three such teeth, the last milk molar and the first and second true molars (or the third, fourth, and fifth of the whole series). In the Elephants the number of ridges on the intermediate molars always exceeds five, but in the Mastodons it is nearly always three or four, and the tooth in front has usually one fewer and that behind one more, so that the ridge formula (*i.e.*, a formula expressing the number of ridges on each of the six molar teeth) of most Mastodons can be reduced either to 1, 2, 3, 3, 3, 4 or 2, 3, 4, 4, 4, 5. The former characterizes the section called *Trilophodon*, and the latter that called *Tetralophodon* by Dr Falconer. These divisions are very useful, as under one or the other all the present known species of Mastodon can be ranged, but observations upon a larger number of individuals have shown that the number of ridges upon the teeth is by no means so constant as implied by the mathematical formulæ given above. Their exact enumeration is even difficult in many cases, as "talons" or small accessory ridges at the hinder end of the teeth occur in various stages of development, until they take on the character of true ridges. Transitional conditions have also been shown, at least in some of the teeth, between the trilophodont and the tetralophodont forms, and again between the latter and what has been called a "pentalophodont" type, which leads on towards the condition of dental structure characteristic of the true Elephants.

The range of the genus *Mastodon* in time was from the middle of the Miocene period to the end of the Pliocene in the Old World, when they became extinct; but in America several species—especially the best-known, owing to the abundance of its remains, which has been variously called *M. ohioticus*, *M. americanus*, and *M. giganteus*—survived quite to a late Pleistocene period.

The range in space will be best indicated by the following list of the generally recognized species. 1. Trilophodont series—*M. angustidens*, *borsoni*, *pentelici*, *pyrenaicus*, *tapiroides* (or *turicensis*), *virgatidens*, from Europe; *M. falconeri* and *pandionis*, from India; *M. ohioticus*, *obscurus*, and *productus*, North America; and *M. andium* and *humboldtii*, South America. 2. Tetralophodont series—*M. arvernensis*, *M. dissimilis* and *longirostris*, from Europe; *M. latidens*, *sivalensis*, and *peramensis*, from India; *M. mirificus*, from North America. The only two of which remains have been found in Great Britain are *M. arvernensis* and *M. borsoni*, both from the crags of Norfolk and Suffolk.

The range of the genus was thus very extensive, and it has even been supposed to reach to Australia, where no Ungulate mammal has ever been proved to exist. This supposition until very recently has been based upon the evidence of a single molar tooth of an animal undoubtedly belonging to *Mastodon*, and alleged to have been brought from near Boree Creek, an affluent of the Lachlan river in the Ashburnham district, New South Wales, by the late Count Strzelecki, and described by Professor Owen in 1844 under the name of *M. australis*. Its identity with the South American *M. andium* has, however, been shown by Dr Falconer, who has thrown grave doubts upon the locality assigned to the specimen. A fragment of a tusk, of the Australian origin of which there is less question, and which presents the characteristic structure only known at present in Elephants and Mastodons, has been lately described by Professor Owen (*Proc. Roy. Soc.*, March 30, 1882). It was found in a drift-deposit of a ravine in a district of Darling Downs, 60 miles to the eastward of Moreton Bay, Queensland. Unfortunately no other portions of the remains of the animal to which it belonged have been discovered.

MAS'ÚDY. Abú'l-Ḥasan ʿAlí ibn Ḥosein ibn ʿAlí el-Mas'údy,[1] was born at Baghdad towards the close of the 9th Christian century. Great part of his life was spent in travel; in 912–13 A.D. he was at Múltán in the Punjab, and also visited Mansúra. Three years later he was at Baṣra and met Abu Zeid, the geographer whose remarks on the extreme East are comprised in Reinaud's *Relation des Voyages* (Paris, 1845). His writings and those of Mas'údy are indebted each to the other. In the interval it would seem our traveller had gained that personal acquaintance with Fars and Susiana, and that knowledge of the books of the Persians, of which he speaks in his writings. Once more turning eastward he was at Cambay in 915–16, and soon after at Ṣaimúr. Hence he pushed on to Ceylon and sailed to Madagascar, returning to ʿOmán in 916–17. In the introduction to the *Meadows* he seems also to say that he had journeyed as far as China. A northern journey carried Mas'údy as far as the Caspian Sea. In 926 he was at Palestine, where his curiosity, not limited by religious prejudice, led him to visit the Christian church and describe its relics. In 943–44 he made a careful study of the ruins of Antioch, and subsequently proceeded to Baṣra. In the same year he composed the *Meadows of Gold*. The last ten years of his life were passed in Syria and Egypt. His last work, *The Indicator and Monitor*, was written 345 A.H., and his death took place in Egypt the same year (956–57 A.D.).[2] The vast journeys of Mas'údy did not pass beyond the lines of commercial enterprise among the Moslems of those days, when 'Iráḳ was not unjustly held to be the centre of the world, and the arms, the trade, and the religion of Islám penetrated to the remotest parts of Asia and Africa. But Mas'údy did not travel for gain. His object was to study with his own eyes the peculiarities of every land, and to collect whatever was of interest for archæology, history, and manners. Singularly free from bigotry—he was himself a Mo'tazilite, one of the heretical sect, as they were reckoned, who held the doctrine of man's free will—he was ready to derive information even from the writings of infidel Persians or of a Christian bishop.[3] In the range of his observations and the naive uncritical honesty with which he records them he has naturally suggested comparison with Herodotus, and so competent a judge as Ibn Khaldún gives him the title of imám of Eastern historians, an epithet precisely parallel to that borne by Herodotus among the historians of the West. The parallel, however, must be taken with great deductions. Of the *Meadows*, the work by which Mas'údy is chiefly known, by far the greater part is an historical compilation, enlivened indeed in some parts by personal recollection of places and the like, but mainly drawn from a vast mass of earlier books[4] which are used in the common paste-and-scissors fashion of Eastern history. Even in the earlier cosmographical chapters the author's vast and miscellaneous reading, which included the Arabic translations of Ptolemy and other Greek writers, is mingled with his original observa-

[1] The surname is derived from an ancestor Mas'úd, a Meccah, whose son 'Abdalla accompanied Mohammed on his flight to Medína, and is often mentioned in the history of the prophet. Details as to the family are given by Reiske, *Ann. Mos.*, vol. i., note 208.

[2] See De Sacy, *Chrest.*, 1st ed., ii. 490.

[3] In the *Meadows*, iii. 69, he tells us that at Fosṭát (Old Cairo), in 336 A.H., there fell into his hands a chronicle (now lost) by Godmer, bishop of Gironne, which he uses for his narrative.

[4] Of these the first chapter gives an interesting catalogue.

tions in that ill-digested style so often characteristic of men of prodigious acquisitive power; and the presentation of facts falls as far short of freshness and the artistic charm of the inimitable Grecian *raconteur* as the shapeless details of universal history, as it appeared to the Moslem, fall short of the epic interest of the great struggle for supremacy between Eran and Hellas.

Mas'údy has himself sketched his literary activity in the opening chapter of the *Meadows* and in his last book *The Indicator*. In his huge *Annals* (*Akhbár el-Zemán*) and in a second work of less extent (*Kitáb el-Awsat*) which followed it he summed up the whole cosmographical and geographical science of his age. These works are lost or known only by fragments, but we possess an abridgment in the author's third great work *The Meadows of Gold and Mines of Precious Stones*, of which there are many MSS. in European libraries. It was printed by Barbier de Meynard with a French translation, 9 vols. 8vo, Paris, 1861–77, and at Búlák in 1867 (2 vols. folio). The first volume of an English translation by Sprenger appeared at London in 1841; but the work was not continued. The Kitáb-el-Tanbíh (*Indicator and Monitor*) exists in MS. at Paris, and has been fully described by De Sacy in *Notices et Extraits*, vol. viii., 1810 (reprinted at the end of the Paris edition of the *Meadows*, where a list of other works of our author is given). See also Quatremère in *Jour. As.* for January 1839, and the article "Masoudy," by Reinaud, in the *Nouv. Biog. Générale*.

MASULIPATAM, the chief town of Kistna district, Madras, India, and a seaport, is situated in 16° 9′ N. lat., 81° 11′ E. long., with a population in 1871 of 36,316. The export trade is partly to Europe; imports are chiefly local. In 1874–75 235 vessels of 106,000 tons burthen visited the port; the exports (oil-seeds and cotton) amounted to £171,400, the imports to £119,600. The town contains the usual district offices, a jail, and several schools, the chief being the high school. It is a flourishing station of the Church Missionary Society.

Masulipatam was the earliest British settlement on the Coromandel coast. An agency was established there in 1611, and a fortified factory in 1622. During the wars of the Carnatic, the English were temporarily expelled the town, which was held by the French for some years. In 1759 the town and fort were carried by storm by Colonel Forde, and it has been held by the British ever since. Weavers form a large portion of the inhabitants of the town, though their trade has greatly declined since the beginning of this century. Their operations, besides weaving, include printing, bleaching, washing, and dressing. In former days the chintzes of Masulipatam had a great reputation abroad for the freshness and permanency of their dyes, the colours becoming brighter after washing than before. There is still a small demand for these articles in Burmah, the Straits, and the Persian Gulf; but steam machinery has nearly beaten the hand-loom out of the field. Another speciality was *metapollams* or kerchiefs for the head; but this industry was ruined by the refusal of the West Indian negroes to wear these kerchiefs after their emancipation. Tartans, ginghams, towels, and table linen are still manufactured to some extent. The importance of the place is now declining, and the garrison was withdrawn in 1865. The heaviest blow to the prosperity of the town was given by the great storm-wave of 1864, which swept over the entire town, and is said to have destroyed 30,000 lives.

MATAMOROS, a city of Mexico, in the province of Tamaulipas, on the southern bank of the Rio Grande, about 35 miles from its mouth, and directly opposite Brownsville in Texas. Built in an open plain, Matamoros has its streets laid out with great regularity; and the general appearance gives evidence at once of its recent rise into importance and of the influence of the architectural fashions of the United States. The principal building is the large but heavy-looking cathedral. An extensive traffic, both legitimate and contraband, is carried on between Matamoros and Brownsville, and in spite of the bar at the mouth of the river, which in foul weather prevents the entrance even of small schooners, the place is not without its value to Mexico as a foreign port. The imports of American and of European goods are valued each at about $1,100,000, with a growing preponderance on the side of the American. Cotton, flax, silk, and woollen goods are the main items in the European list; cottons, leaf tobacco, wheat-flour, machinery, and preserved meats in the American. Hides and skins, live animals, and wool are the principal exports apart from coin and bullion, which are largely smuggled to avoid the export duty. The population is about 20,000.

Founded in the beginning of the century, and named in honour of the Mexican patriot Mariano Matamoros, the city has played a part in all the more recent wars. It was captured by General Taylor of the United States in 1846, was in the hands of the imperialists under Majia in 1864, and was occupied by the French in 1866.

MATANZAS, or San Carlos de Matanzas, a city and seaport on the north coast of Cuba, and the chief town of a province, lies 52 miles east of Havana, with which it is connected by rail. It is a well-built place of from 36,000 to 40,000 inhabitants, occupying a fine site at the head of the Bay of Matanzas, and separated from its suburbs Pueblo Nuevo and Versailles by the San Juan on the one hand and the Yamurri on the other. In the centre of the principal square is a statue of Ferdinand VII., and along the east side runs the residence of the commandant. The new theatre is the handsomest building of its kind in Cuba, and the Empresa Academy has the repute of being one of the best educational institutions in the West Indies. As a commercial centre Matanzas ranks next to Havana, having risen rapidly after the removal of the old trade restrictions in 1809. The exports are mainly sugar and molasses. The harbour has been deteriorated by the mud brought down by the San Juan; but the bay is well sheltered from all winds except the north-east, which brings in a heavy sea. Matanzas was founded in 1693 by a number of immigrants from the Canary Islands, and in the same year Bishop Compostello laid the first stone of the cathedral. The city suffered severely from a conflagration in 1845. About 2½ miles to the east are the beautiful stalactite caves of Bellamar, about 3 miles in extent.

MATARÓ, a Mediterranean seaport of Spain, in the province of Barcelona, 21 miles to the north-east of that city, is beautifully situated on the lower slopes and at the foot of the range of hills which skirt the coast, and shelter the town from the cold northern winds. The streets of the new town, lying next the sea, are wide and regularly built; those of the old town, farther up the hill, still preserve much of their ancient character. The parish church of Santa Maria has some good pictures and wood carvings; other prominent public buildings are the theatre, the civil hospital, and the establishments of the Padres Escolapios. There are small schools of navigation and the fine arts. The wine of the neighbourhood, which somewhat resembles port, is shipped in large quantities from Barcelona; and the district furnishes fine roses, strawberries, and similar produce for the Barcelona market. There is a considerable fishery, the products of which are sent inland to Manresa and other places. The leading industries of Mataró are its linen, woollen, and cotton manufactures, especially of canvas and tarpaulin; several hundreds of women are employed in the town and neighbourhood in lace-making; there are also potteries, machine-making, and chemical works, and shipbuilding is carried on to some extent. The railway to Barcelona, opened in October 1848, was the first to be constructed in Spain. Mataró has no artificial harbour, several attempts to make one having failed; the trade is carried on chiefly through Barcelona. The population in 1877 was 17,405. Outside the town is the much-frequented carbonated mineral spring of Argentona.

MATCHES. Till the close of the 18th century flint and steel with tinder box and sulphur-tipped splints of wood—"spunks" or matches—were the common means of obtaining fire for domestic and other purposes. The sparks struck off by the percussion of flint and steel were made to

fall among the tinder, which consisted of carbonized fragments of cotton and linen; the entire mass of the tinder was set into a glow, developing sufficient heat to ignite the sulphur with which the matches were tipped, and thereby the splints themselves were set on fire. Instead of tinder, match-paper or touch-paper, a thick bibulous paper impregnated with saltpetre (nitrate of potash), and amadou or German tinder, a thick leathery and porous preparation from the fungus *Polyporus fomentarius*, were often used.

It was not till 1805 that any attempt was made to use chemical agency for the ordinary production of fire. In that year M. Chancel, assistant to Professor Thenard of Paris, introduced an apparatus consisting of a small bottle containing asbestos, saturated with strong sulphuric acid, with splints or matches coated with sulphur, and tipped with a mixture of chlorate of potash and sugar. The matches so prepared, when brought into contact with the sulphuric acid in the bottle, ignited, and thus, by chemical action, fire was produced. It appears also that in the same year phosphorus matches were known in Paris, and in 1809 Derepas proposed to lessen the dangerously great inflammability of the phosphorus match by making an igniting mixture of that element with magnesia. It is also said that M. Derosne made a friction match with a phosphorus tip in 1816. Again in 1823 a phosphorus match was proposed, but it came into little use. In this case the composition consisted of equal parts of phosphorus and sulphur cautiously melted together in a glass tube. The tube was then securely corked, and, to obtain a light, a splint was introduced into the mixture, and a small pellet detached, which on withdrawal and exposure almost spontaneously ignited. In that year (1823) a decided impetus was given to the artificial evolution of fire by the introduction of the Döbereiner lamp, so called after its inventor Professor Döbereiner of Jena. The action of this elegant invention depends on the remarkable property possessed by spongy or highly porous platinum of determining the combination of hydrogen and oxygen and the formation of water at common atmospheric temperatures. In the Döbereiner lamp hydrogen is evolved in a suitable vessel by the action of zinc on acidulated water. The gas so liberated, when required, is passed through a fine orifice by means of a stop-cock, and impinging on a mass of spongy platinum mounted in a frame it combines with oxygen of the air, thereby developing an intense heat, which quickly causes the platinum to glow, and ultimately is sufficiently intense to set the stream of hydrogen itself on fire. The Döbereiner lamp is still occasionally seen, but it is chiefly used in connexion with chemical lectures.

The first really practical friction matches were made in England in 1827, by Mr John Walker, a druggist of Stockton-on-Tees. These were known as "Congreves" after Sir William Congreve, Bart., the inventor of the Congreve rocket, and consisted of wooden splints or sticks of cardboard coated with sulphur and tipped with a mixture of sulphide of antimony, chlorate of potash, and gum. With each box of eighty-four, which was retailed at a shilling, there was supplied a folded piece of glass paper, the folds of which were to be tightly pressed together, while the match was drawn through between them. In 1830 the so-called "Prometheans" were patented by Mr S. Jones of London. These consisted of a short roll of paper with a small quantity of a mixture of chlorate of potash and sugar at one end, a thin glass globule of strong sulphuric acid being attached at the same point. When the sulphuric acid was liberated by pinching the glass globule, it acted on the mixed chlorate and sugar, producing fire.

The phosphorus friction match of the present day was first introduced on a commercial scale in 1833; and it appears to have been made almost simultaneously in several distinct centres. The name most prominently connected with the early stages of the invention is that of Preschel of Vienna, who in 1833 had a factory in operation for making phosphorus matches, fusees, and amadou slips tipped with igniting composition. At the same time also matches were being made by Moldenhauer in Darmstadt; and for a long series of years Austria and the South-German states were the principal centres of the new industry. Improvements in the manufacture have been numerous; and the industry is now carried on with a complete system of ingenious labour-saving machinery. The use of phosphorus as a principal ingredient in the igniting mixture of matches has not been free from very serious disadvantages. It is a deadly poison, the free dissemination of which has led to many accidental deaths, and also to numerous cases of wilful poisoning and suicides. Workers also who are exposed to phosphoric vapours are subject to a peculiarly distressing disease which attacks the jaw, and ultimately produces necrosis of the jaw-bone; it appears, however, that, with scrupulous attention to ventilation and cleanliness, almost all risk of the disease may be avoided. Strenuous efforts have been made by numerous inventors to introduce matches having no phosphorus in their igniting mixture, but hitherto with indifferent success. The most serious objections to the use of phosphorus have, however, been overcome by the discovery of the modified condition of that body known as red or amorphous phosphorus, made by Professor Anton Von Schrötter of Vienna in 1845, and the utilization of that substance in the now well-known "safety matches" invented by Lundström of Sweden in 1855, and first manufactured in the United Kingdom by Bryant & May of London. Red phosphorus is, in itself, a perfectly innocuous substance, and no evil effects arise from freely working the compositions of which it forms an ingredient. The fact again that safety matches ignite only in exceptional circumstances on any other than the prepared surfaces which accompany the box—which surfaces and not the matches themselves contain the phosphorus required for ignition—makes them much less liable to cause accidental fires than the kinds more commonly in use.

*Manufacture.*—The operations carried on in a match factory may be grouped under the four heads of preparing the splints, dipping the matches, box-making, and filling. The varieties of wood principally used for matches are poplar, aspen, yellow pine, and white pine. Splints are either round or quadrangular, the former having been at one time exceedingly common, when Austrian manufactures ruled the markets; but, now that Sweden is the principal match-manufacturing country, matches are nearly all square in section. For cutting square splints many ingenious machines have been devised, some of which, worked by engine-power, can turn out from 15,000,000 to 17,000,000 splints per day. In Sweden the manufacturers use principally aspen or clean-grained pine wood, preferring sections 12 to 20 inches in diameter, newly felled and full of sap. If dry, the wood must be soaked before it is fit for the operations through which it passes. The timber is cut into blocks about 15 inches long—sufficient for seven matches—and being freed from bark it is fixed in a special form of turning lathe, and by means of a fixed cutting tool acting on its entire length a continuous veneer or band the thickness of a match is cut off. With each revolution of the block the knife advances proportionately to the thickness of the band cut off, and thus a uniformly thick slice is obtained continuously. At the same time eight small knives cut the veneer into seven separate bands each the length of a match, and thus in one operation seven long ribbons of wood the length and thickness of a match are obtained. These ribbons are next broken into lengths of from 6 to 7 feet, knotty pieces are removed, and to cut them into single matches they are fed into a machine which acts somewhat like a straw-chopper. From 120 to 140 bands are acted on in the apparatus, and a ratchet arrangement feeds them forward, the thickness of a match at each stroke of the cutter, which thus cuts off 120 to 140 matches per stroke. Worked by hand the machine delivers about 5,000,000 splints per day, and by power it can be run to turn out double that number. The matches are next

dried in revolving drums in a heated chamber or stove, and thereafter they are sifted in a kind of partitioned sieve to free them from fragments and splinters. The sifting process also arranges all the splints in parallel order and in uniform quantities, whereby they may be conveniently bundled and prepared for the dipping which next follows. For the dipping process it is necessary to keep each match free from contact with its neighbour, and indeed allow it such a space that each may be fully coated and yet there be no danger of the igniting composition clotting the heads into one mass. To effect this the splints are by an ingenious machine separately arranged at uniform intervals between the lathes of a dipping frame. The dipping frames are made about 18 inches square, and are fitted with 44 movable lathes. Between each pair of lathes 50 splints are inserted by the machine, and when tightened up by screws each frame thus contains $44 \times 50 = 2200$ splints placed at regular intervals, the heads of which are all on the same level. A single attendant can place, by aid of the machine, about 1,250,000 matches in the dipping frames per day. The dipping is done in a stove of masonry which contains three square flat-bottomed shallow pans. In the first the splints are heated so as to facilitate the absorption of paraffin; in the second their points are dipped into molten paraffin scale; and in the third they receive their heads or tips of igniting composition, that mixture being kept in a uniform thin stratum in the pan, or in some cases it is supplied by an endless india-rubber belt which revolves and dips into the composition. A skilful workman can dip from 3500 to 4000 frames, or about 8,000,000 matches, a day. The frames so dipped are afterwards arranged in a heated apartment till the igniting composition is dried, after which the matches are taken out and put up in boxes by hand.

Match splints in the factories of the United Kingdom are generally cut in lengths suitable for two matches, and dealt with in that form throughout. The splint-cutting machine patented by John Jex Long of Glasgow in 1871 differs essentially from the Swedish splint-making machinery above alluded to; it acts on squared blocks two-match length, and is capable of producing up to 17,000,000 matches per day.

The object of dipping in melted paraffin is, of course, to secure more ready ignition of the wood. Sulphur was formerly employed for that purpose; and enormous quantities of the cheaper matches made on the Continent and in America continue to be sulphur dipped. The cheaper kinds are frequently "bundle dipped" in the molten sulphur, after which their points are merely pressed against the igniting composition.

The chief element in the igniting mixture of ordinary matches is still common phosphorus, combined with one or more other bodies which readily part with oxygen under the influence of heat. Chief among these latter substances is chlorate of potash, the body which causes the sharp explosive sound when a common match is struck, and to the use of which there is a strong objection on the Continent from the fear of explosions in dealing with the substance in large quantities. The other oxygen-yielding bodies commonly found in matches are red lead, nitrate of lead, bichromate of potash, and peroxide of manganese. The proportions in which any of these bodies is present in various igniting compositions are kept trade secrets; they vary greatly, as special regard must be given to matches for damp climates, or for ocean transport, and to other considerations. The igniting agents are made into a paste with glue or gum as an adhesive agent, a little fine sand or powdered glass, and some colouring ingredient such as cinnabar, smalt, magenta, or Prussian blue. Matches in which amorphous phosphorus takes the place of the common variety, notwithstanding several obvious advantages, have never come into general use. They were shown in the Great Exhibition of 1851 by Bell & Black of London; and Foster & Warwa of Vienna, one of the earliest match-making firms, long continued to make them, as did also Cogniet Père et Fils of Paris. As made by these and other makers they were difficult to strike, requiring a special rough rubbing surface; the head frequently broke away in the attempt to light them, and when they did inflame it was with explosive violence and a loud spluttering noise. Dr Von Schrötter, the discoverer of amorphous phosphorus, claims to have found a means of preparing combinations of amorphous phosphorus with chlorate of potash and other oxygen-yielding compounds of all degrees of combustibility, and he states that Hochstätter of Frankfort now manufactures matches with amorphous phosphorus composition which may be ignited by rubbing on a cloth surface, which inflame quietly, burn without smell or sparking, are not influenced by damp, and are cheaper than common phosphorus matches. The use of amorphous phosphorus—but on the rubbing surface only and not in the dipping composition (safety matches)—was first suggested by Böttger, but it was not till a patent was secured by Lundström in 1855 that the matches were brought into the market. According to J. G. Gentele, the elements of the dipping mixture for the heads are—chlorate of potash, 32 parts; bichromate of potash, 12; red lead, 32; sulphide of antimony, 24; and the ingredients of a suitable rubbing surface are eight parts of amorphous phosphorus to nine of sulphide of antimony. There is no doubt, however, that here too there is considerable diversity in the composition of the mixtures. Igniting compositions entirely free from phosphorus depend for their moderate degree of efficiency on the use of such agents as chlorate of potash, sulphide of antimony, bichromate of potash, and red lead.

"Vestas" are matches in which short pieces of "wax taper" are used in place of wooden splints. The taper is prepared by drawing a series of wicks or strands of twenty to thirty fine cotton threads through molten stearin, with some proportion of paraffin. The wax quickly hardens on the threads, agglutinating them to irregular hard strands, which are smoothed and rounded to the required size by being drawn through iron plates perforated with holes the size of the required taper. The tapers are cut to the match lengths, and set in dipping frames by special machines. The making of vestas is an industry only second in extent to the wooden match manufacture,—its headquarters being London, Manchester, Marseilles, and the north of Italy. Fusees for the use of smokers are made of strips of thick porous paper saturated with saltpetre and bichromate of potash, and tipped with ordinary composition. They are now almost entirely supplanted by vesuvians, which consist of large oval heads on both ends of a round splint. These heads, made by repeated dipping, consist of a porous mixture of charcoal, saltpetre, cascarilla or other scented bark, glass, and gum, and they also are tipped with common igniting composition.

Ordinary match boxes are made of thin veneers or skillets of wood the same as used in splint making. The blocks used yield skillets the exact size of the box or cover to be made, and the machine which shaves skillets off the block also scores them along the lines by which they must be bent to form the box. The folding, covering with paper, and labelling are operations performed by young girls with remarkable rapidity. In dealing with double splints, the matches are at the boxing stage cut asunder in small bundles with a lever knife by the box filler, who acquires such delicacy of perception that at each operation she seizes and divides the exact quantity required to fill two boxes. A good hand will in this way fill 35 to 40 gross of boxes per day.

It is calculated that in the principal European countries from six to ten matches are used for each inhabitant daily. There is no way by which an exact estimate of the extent of the trade in the United Kingdom can be obtained; but competent authorities believe the yearly value of the matches made to be not less than £1,500,000, and that the makers turn out about 300,000,000 matches daily. Of all the makers Messrs Bryant & May are by far the most extensive; and next comes the Bell & Black company, formed of a combination of makers in London, Glasgow, Manchester, and York. In France the right to manufacture matches is a Government monopoly farmed to the *Compagnie générale des allumettes chimiques* for an annual payment of 16,000,000 francs, with 6 centimes extra per hundred matches in excess of forty milliards sold yearly. The company has concentrated the whole of the manufacture into twelve establishments, the largest of which are at Marseilles. The effect of the monopoly in France is that matches are very costly, and the average consumption per head throughout the country is considerably less than in other countries. Sweden is the country which in recent years has been most intimately identified with the growth of the industry. In that country, including with it Norway, there were in 1880 forty-three match factories, many of them large, that of Jönköping being among the most extensive in the world. The quantity of matches exported that year was about 19,000,000 lb (12,900,000 skal-punds), probably representing 50,000,000,000 matches. The yearly exports have increased four-fold since 1870, and are still rapidly extending. In Germany there are two hundred and twelve factories, which are estimated to make yearly about 60,000,000,000 matches; and Austria-Hungary—the original seat and centre of the manufacture—possesses one hundred and fifty establishments, whence large quantities of matches are exported to Russia, Turkey, Asia Minor, and the neighbouring states of Italy. Throughout Europe about 1200 tons of phosphorus are annually consumed in the manufacture of matches, the greater proportion being produced in England.

In the United States a tax of 1 cent per box containing one hundred is levied on matches manufactured in the country, in addition to which there is an *ad valorem* duty of 35 per cent. on all matches imported. The internal revenue tax of a cent per box is subject to a reduction of 10 per cent. to manufacturers, with an additional discount of 5 per cent. on the purchase of the stamps used for the boxes when quantities exceeding in value $50 are purchased at one time. The result of these fiscal arrangements has been to favour large monopolizing companies. Although there are nearly thirty manufactories in the States at present, practically the match trade of the country is in the hands of, or entirely controlled by, the Diamond Match Company of New York, consisting of a combination of large manufacturers. During the year 1881 the revenue derived from the internal tax amounted to $3,272,258, while the customs duty on imported matches yielded no more than $6186, these receipts representing probably a consumption of 40,000,000,000 matches.

(J. PA.)

MATÉ, or PARAGUAY TEA, consists of the dried leaves of *Ilex paraguayensis*, St Hil.,[1] an evergreen shrub or small tree belonging to the same natural order as the common holly, a plant to which it bears some resemblance in size and habit. The leaves are from 6 to 8 inches long, shortly-stalked, oblong wedge-shaped, rounded at the upper end, and finely toothed at the margin. The small white flowers

Maté (*Ilex paraguayensis*).
Portion of plant, half natural size. Flower drupe and nuts, twice natural size. Part of underside of leaf showing minute glands, natural size.

grow in forked clusters in the axils of the leaves; the sepals, petals, and stamens are four in number; and the berry is 4-seeded. The plant grows abundantly in Paraguay, Corrientes, Chaco, and the south of Brazil, forming woods called *yerbales*. One of the principal centres of the maté industry is the Villa Real, a small town above Asuncion on the Paraguay river; another is the Villa de San Xavier, in the district between the rivers Uruguay and Parana.

Although maté appears to have been used from time immemorial by the Indians, the Jesuits were the first to attempt its cultivation. This was commenced at their branch missions in Paraguay and the province of Rio Grande de San Pedro, where some plantations still exist, and furnish the best tea that is made. From this circumstance the names Jesuits' tea, tea of the Missions, St Bartholomew's tea, &c., are sometimes applied to maté. Under cultivation the quality of the tea improves, but the plant remains a small shrub with numerous stems, instead of forming, as in the wild state, a tree with a rounded head. From cultivated plants the leaves are gathered every two or three years, that interval being necessary for restoration to vigorous growth. The collection of maté is, however, chiefly effected by Indians employed for that purpose by merchants, who pay a money consideration to Government for the privilege.

When a yerbal or maté wood is found, the Indians, who usually travel in companies of about twenty-five in number, build wigwams and settle down to the work for about six months. Their first operation is to prepare an open space, called a *tatacua*, about 6 feet square, in which the surface of the soil is beaten hard and smooth with mallets. The leafy branches of the maté are then cut down and placed on the tatacua, where they undergo a preliminary roasting from a fire kindled around it. An arch of poles, or of hurdles, is then erected above it, on which the maté is placed, a fire being lighted underneath. This part of the process demands some care, since by it the leaves have to be rendered brittle enough to be easily pulverized, and the aroma has to be developed, the necessary amount of heat being only learned by experience. After drying, the leaves are reduced to coarse powder in mortars formed of pits in the earth well rammed. Maté so prepared is called *caa gazu* or *yerva do polos*, and is chiefly used in Brazil. In Paraguay and the province of Parana in the Argentine Republic, the leaves are deprived of the midrib before roasting; this is called *caa-miri*. A very superior quality, or *caa-cuys*, is also prepared in Paraguay from the scarcely expanded buds. More recently a different method of drying maté has been adopted, the leaves being heated in large cast iron pans set in brick work, in the same way that tea is dried in China; it is afterwards powdered by machinery.

The different methods of preparation influence to a certain extent the value of the product, the maté prepared in Paraguay being considered the best, that of Oran and Paranagua very inferior. The leaves when dried are packed tightly in serons or oblong packages made of raw hides, which are then carefully sewed up. These shrink by exposure to the sun, and in a couple of days form compact parcels each containing about 200 lb of tea; in this form it keeps well. The tea is generally prepared for use in a small silver-mounted calabash, made of the fruit of *Crescentia Cujete* (Cuca) or of *Cucurbita lagenaria* (Cabaço), usually about the size of a large orange, the tapering end of the latter serving for a handle. In the top of the calabash, or *maté*,[2] a circular hole about the size of a florin is made, and through this opening the tea is sucked by means of a bombilla. This instrument consists of a small tube 6 or 7 inches long, formed either of metal or a reed, which has at one end a bulb made either of extremely fine basket-work or of metal perforated with minute holes, so as to prevent the particles of the tea leaves from being drawn up into the mouth. Some sugar and a little hot water are first placed in the gourd, the yerva is then added, and finally the vessel is filled to the brim with boiling water, or milk previously heated by a spirit lamp. A little burnt sugar or lemon juice is sometimes added instead of milk. The beverage is then handed round to the company, each person being furnished with a bombilla. The leaves will bear steeping about three times. The infusion, if not drunk soon after it is made, rapidly turns black. Persons who are fond of maté drink it before every meal, and consume about 1 oz. of the leaves per day. In the neighbourhood of Parana it is prepared and drunk like Chinese tea. Maté is generally considered disagreeable by those unaccustomed to it, having a somewhat bitter taste; moreover, it is the custom to drink it so hot as to be unpleasant. But in the south-eastern republics it is a much-prized article of luxury, and is the first thing offered to visitors. The *gaucho* of the plains will travel on horseback for weeks asking no better fare than dried beef washed down with copious draughts of maté, and for it he will forego any other luxury, such as sugar, rice, or biscuit. Maté acts as a restorative after great fatigue in the same manner as tea. Since it does not lose its flavour so quickly as tea by exposure to the air and damp, it is more valuable to travellers.

Some writers attribute delcterious effects to its use, while others praise it to an almost incredible degree. Its physiological action does not appear to have been carefully worked out, but its extensive use in countries where tea and coffee are known seems to indicate that it may possess virtues peculiar to itself.

Its properties appear to be chiefly due to theine or caffeine. Analysed by Dr H. Byasson, 100 grains were found to yield

| | Grains. |
|---|---|
| Caffeine | 1·850 |
| Glutinous substance or peculiar fatty matter and colouring matter | 3·870 |
| Complex glucoside | 2·380 |
| Resin | 0·630 |
| Inorganic salts, including iron | 3·920 |
| Malic acid not estimated. | |

[1] Mr J. Miers has proved that *I. curitibensis*, *I. giguntea*, *I. ovalifolia*, *I. Humboldtiana*, and *I. nigropunctata*, besides several varieties of these species, are in general use for preparing maté.

[2] The word *caa* signified the plant in the native Indian language. The Spaniards gave it a similar name, *yerba*. *Maté* comes from the language of the Incas, and originally means a calabash. The Paraguay tea was called at first *yerva do maté*, and then, the *yerva* being dropped, the name *maté* came to signify the same thing.

According to analyses made by Alonzo Robbins it also contains about 1·5 of a peculiar tannin which does not precipitate potassio-tartrate of antimony, nor tan leather. The glutinous substance resembles in consistence common birdlime, and is considered by Byasson to be a compound ether, the alcohol of which would be near cholesterin. Since the beginning of the 17th century maté has been drunk by all classes in Paraguay, and it is now used throughout Brazil and the neighbouring countries. In 1855 the amount of maté annually consumed in South America was estimated by Von Bibra at 15,000,000 lb, and the consumption is now probably three or four times as great; in Brazil it brings in a revenue of about £410,000. In the Argentine Republic alone the consumption is not less than 27,000,000 lb per annum, or about 13 lb per head, while the proportion of tea and coffee consumed is only about 2 lb of the former and ½ lb of the latter per head. The export of maté from Brazil to foreign countries has also increased from 2,720,475 kilos in 1840 to 5,206,485 kilos in 1850, 6,808,056 kilos in 1860, 9,507,086 kilos in 1870, and 14,063,731 kilos in 1879–80.

MATERA, a city of Italy in the north-east of the province of Potenza, 48 miles from Potenza, on the high road to Bari. Part of it is built on a level plateau and part in deep valleys adjoining, the tops of the campaniles of the lower portions being on a level with the streets of the upper. The principal building is the co-cathedral of the archbishopric of Acerenza and Matera, formed in 1203 by the union of the two bishoprics, dating respectively from 300 and 398. In 1871 the population of the commune was 14,312 (that of the city 14,262), in 1881 15,700.

Under the Normans Matera, the ancient Mateola, was a countship for William Bras de Fer and his successors. It was the chief town of the Basilicata from 1664 till 1811, when the French transferred the administration to Potenza.

## MATHEMATICAL DRAWING AND MODELLING.

The necessity for geometrical drawings and models is as old as geometry itself. The figure has formed the basis of many a geometrical truth; and demonstration by mere inspection of this has frequently to do service for more rigorous proof. So necessary is this visual representation of an idea that there is hardly a branch of mathematics which does not make use of it in the form of tables, symbols, formulæ, &c. The visual method is especially important in geometry. The figure is to the geometer what the numerical example is to the algebraist—on the one hand limiting the horizon, on the other imparting life to the conception. Herein lies the didactic value of the figure, which is the more indispensable the more elementary the stage of instruction. To be able to dispense with it is a faculty acquired only after a long and special training. The power of mental picturing is a talent which can be so strengthened by use that even a slightly gifted mind may acquire the power of carrying out a series of geometrical operations without the aid of a figure, provided these do not lead into unfamiliar regions. But each new group of ideas which the geometer would master requires a new graphic setting forth, which not even the experienced can dispense with. Drawings are sufficient in plane geometry; but solid geometry requires models, except in specially simple cases, in which delineation by means of perspective or some conventional method may suffice. Then, again, in passing from the geometry of the plane, straight line, and point in space to that of curved surfaces, tortuous curves, &c., new and distinct graphical methods are necessary. The difficulties encountered in understanding new groups of geometrical forms are best removed by a careful study of a small number of characteristic models and drawings. As a means of education, the model is lively and suggestive, forming in this way a completing factor in the course of instruction. We remember the pleasure experienced when, after a discussion which has yielded a series of hardly reconcilable properties of one and the same geometrical figure, a model is exhibited which combined these properties in itself; or the striking manner in which a deformable model either of pasteboard or thread executes its transformations before the eye of the observer and scientific student. The study of the model raises new and unexpected questions, and can even do valuable service in leading to new truths.

In the more elementary departments of plane and solid geometry and descriptive geometry, models are abundant and easily obtainable; but there are comparatively few collections of drawings and models for instruction in higher geometry. There are numerous drawings of algebraic and transcendental curves in the well-known treatises on analytical geometry of Cramer, Euler, Salmon, in Frost's *Curve Tracing*, &c.; but there is still a deficiency in systematic enumerations of the forms of curves and surfaces of a given order or class. In this connexion we may mention Plücker's *System der analytischen Geometrie* (curves of the third order), and Beer's *Enumeratio linearum IV. ordinis*. A graphical representation of all the characteristics of the singular points of an algebraic curve of the fourth order is given in Zeuthen's *Systemer af plane Kurver* (1873). As regards tridimensional figuring, the oldest known models for instruction in the higher geometry are the thread models of skew surfaces constructed about the year 1800 under the direction of G. Monge for the École Polytechnique in Paris. In 1830 Th. Olivier of Paris got the same executed in movable form. The great development in modern times of certain branches especially of the higher geometry has given a new importance to such methods of graphical representation.

Amongst the larger collections we must mention the elegant series of complex surfaces, consisting of twenty-seven items, constructed by the celebrated J. Plücker of Bonn. After Plücker's death copies, not very satisfactory, were made from zinc casts. The collection of plaster and thread models published by Muret of Paris (now Delagrave), and intended for instruction in descriptive geometry, contains many architectural forms. The wire models of tortuous curves by Professor Wiener of Carlsruhe, and the thread-models of developable surfaces by Professor Björling of Lund, merit notice amongst others. Perhaps the largest and most extensive of the collections is that of L. Brill, bookseller in Darmstadt. These represent every department of the higher and applied mathematics. The catalogue embraces some seventy numbers, with over a hundred plaster, thread, and metal models. Several series of this collection were prepared in the mathematical department of the technical college of Munich. In the preparation of these models, involving the development of a comparatively novel art, certain practical lessons were gained, especially in the working of plaster models, to which we may direct attention.

We assume that the preliminary designs are prepared with the aid of board, ruler, square, compasses, and such well-known instruments as are used by the draughtsman.

The material to be employed, whether wire or thread, interlaced pasteboard strips, or plaster, depends upon the special circumstances of each case, and upon the purpose aimed at in the construction of the model. Two bundles of parallel disks of cardboard or metal-sheeting, inclined at an adjustable angle, may be used with advantage in representing a series of different but mutually transformable surfaces. For ruled and developable surfaces the thread model is to be recommended. The surface is enclosed in a cube, or more generally in a region of space bounded by plane walls. Upon these bounding walls are marked the series of points in which they are cut by the generative lines that are to be represented by threads. Through these points the threads are drawn, and parts of the supporting walls are then cut away so as to allow a convenient glance into the interior of the region. The more densely the threads are strung, the liker is the appearance to that of a continuous surface.

In the majority of cases plaster will be found the most convenient substance, being easily worked, and giving a result convenient and clear to the eye. There is the disadvantage, however, that one of the regions of space bounded by a surface is filled up. Should the

boundaries of the surface be plane or capable of being turned on the lathe, the desired form is best approximated to by working wood or plaster blocks. Plaster is not easily worked on the lathe, but a plane surface is readily got by rubbing, and if not too dry it may be cut with the knife.

A surface which cannot be conveniently approximated to by the above method may be built up of strips cut to pattern, which are then filled in with some plastic material. To accomplish this, a system of sections either parallel or having a single axis is laid through the region to be filled up; the bounding lines of these sections are calculated or obtained by geometrical construction. Strips of plate zinc are then cut to the required form and fixed securely by cross-pieces or soldered if necessary. Between the interstices of this zinc scaffolding some plastic material is filled in, such as embossing wax or damp clay; and thus the form of the surface is rendered. The substance known in trade as plastilin is especially suitable for use in this way, as it retains its plastic property a long time. The finishing touches are given to the surface by means of a sculptor's style. From the clay model a plaster cast is formed and well dried; and its imperfections are removed by means of plaster-files and other instruments familiar to those who work in plaster. Lines which are to be shown on the model are drawn through points already marked on the original clay model, and engraved with fine files. A galvanoplastic copy of such a plaster model, not too deeply deposited, shows the surface even better than the plaster itself.

MATHEMATICS. Any conception which is definitely and completely determined by means of a finite number of specifications, say by assigning a finite number of elements, is a mathematical conception. Mathematics has for its function to develop the consequences involved in the definition of a group of mathematical conceptions. Interdependence and mutual logical consistency among the members of the group are postulated, otherwise the group would either have to be treated as several distinct groups, or would lie beyond the sphere of mathematics.

As an example of a mathematical conception we may take "a triangle"; regarded without reference to its position in space, this is determined when three elements are specified, say its three sides; or we may take a "colour sensation," which, on Young's theory, is determined when the amounts of the three fundamental colour sensations that enter into it are stated. As an example of a non-mathematical conception we may take "a man," "a mineral," "iron," no one of which admits of being so determined by a finite number of specifications that all its properties can be truly said to be deducible from the definition.

A mathematical conception is, from its very nature, abstract; indeed its abstractness is usually of a higher order than the abstractness of the logician. Thus, for instance, we may neglect the other attributes of a body and consider merely its form; we thus reach the abstract idea of "form." But the form of an irregular fragment of stone does not admit of being finitely specified, and is therefore not susceptible of mathematical treatment. If, however, we have a carefully squared cubical block of granite to deal with, for most practical purposes its form is specified by stating that it is a cube, and assigning one element, viz., an edge of the abstract mathematical cube by which we replace it. This example illustrates at once the limits of mathematical reasoning and the nature of the bearing of mathematics on practice.

A variety of words have been used to denote the dependence of a mathematical conception upon its elements. It is frequently said, for instance, that the conception is a "function" of its elements. One word has recently come into use which is very convenient, inasmuch as it draws attention at once to the fundamental idea involved in mathematical conception and to the prime object of mathematical contemplation, viz., "manifoldness."

Number is involved in the notion of a manifoldness both directly, as any one can see, and also indirectly in a manner which the mind untrained to mathematical thinking does not so readily understand. Take on the one hand the case of a triangle considered without reference to its position but merely as composed of three limited straight lines, it may be completely determined in various ways by assigning three elements. A triangle may therefore be called a triple discrete manifoldness. A plane quadrilateral considered in the same way (being fully determined when four sides and a diagonal are known) is a quintuple discrete manifoldness; and a plane polygon of $n$ sides a $(2n-3)$-ple discrete manifoldness. Consider on the other hand the assemblage of points on a given straight line, they are infinite in number yet so related that any one of them is singled out by assigning its distance from an arbitrarily chosen fixed point on the line. Such an assemblage is called a onefold continuous manifoldness, or simply a onefold manifoldness; another example of the same kind is the totality of instants in a period of time. The assemblage of points on a surface is a twofold manifoldness; the assemblage of points in tridimensional space is a threefold manifoldness; the values of a continous function of $n$ arguments an $n$-fold manifoldness.

It should be observed that the distinction between discrete and continuous manifoldness is not of necessity inherent in the conception. For one purpose we may treat a conception as a discrete manifoldness, for another as a continuous manifoldness. Thus we have seen that an unlimited straight line may be treated as a onefold continuous manifoldness; but, if we regard it as a whole, and with reference to the fact that its position in space is determined by four data, it becomes a quadruple discrete manifoldness.

The primary, although not the only, operation in the treatment of a discrete manifoldness is numbering or counting; hence arises the pure mathematical science of number, comprehending (abstract) *Arithmetic* and its higher branch commonly called the *Theory of Numbers*. Without entering into a discussion of the definitions and axioms of the science of number, it will be sufficient here to remark that all numerical operations are reducible to three fundamental laws commonly called the commutative, associative, and distributive laws. The four fundamental processes, or four species, as they are sometimes called, two of which, addition and multiplication, are direct, and two, subtraction and division, inverse, are solely defined by and derive their meaning from the three laws of operation just mentioned.

A careful consideration of the methods in vogue for dealing with continuous manifoldness shows that they reduce themselves to two, which may be called the synoptic method and the analytic method. In the synoptic method we deduce the properties of a manifoldness by contemplating it as a whole, aiding our understanding, when it is necessary to do so, by a diagram, a model, or any other concrete device more or less refined according to circumstances. In the analytic method we fix our attention upon the individual elements of the manifoldness, usually defining each element by a definite number of specifications the variation of which leads us from element to element of the given manifoldness. We examine the properties of an element in the most general manner, and from them we predicate the properties of the manifoldness as a whole.

The best and most familiar examples of the synoptic treatment of manifoldness are the different varieties of pure geometry. Among these we may mention the apagogic geometry of the Greeks, which starts with a collection of definitions and axioms, enunciates and proves proposition after proposition with great attention to strict logical form and with continual reference to the grounds of inference, but pays little attention to the ordering of theorems with a view to mutual illustration, and carefully suppresses all traces of the method by which the propositions were or might have been discovered. It is true that the Greeks

were in possession of a method, called by them analysis, which had for its object the discovery of geometrical truth. But this consisted merely in taking any proposition suspected to be true and tracing its consequences until one was reached which either contradicted a known proposition or else was true and capable of leading by a direct process of reasoning (synthesis) to the proposition in question. In this we have no trace of the systematic development of geometric truth, and the method was apparently regarded by the ancients themselves as imperfect, for it makes no figure in such of their systematic treatises as have reached us. In somewhat sharp contrast with the Grecian geometry, but still essentially synoptic in method, stand the different varieties of modern geometry,—which aims at greater generality in its definitions, pays less explicit attention to logical form, but arranges geometrical propositions as much as possible in the natural order of development or discovery, and above all makes extensive use of the principle of continuity. As examples of the modern geometry may be cited the descriptive geometry (*Géométrie Descriptive, Darstellende Geometrie*) of Monge; the projective geometry (*Géométrie Projective, Geometrie der Lage*) of Poncelet, Steiner, and Von Staudt; and the geometry of transformation in general, of which projective geometry is but a particular case. There is one other highly interesting form of modern geometry, which, although analytic in some of its developments, and often exhibited in close alliance with other analytical methods, is nevertheless synoptic as to its fundamental principle, viz., arithmic geometry (*Abzählende Geometrie*) or theory of characteristics, which originated in the characteristic equations of Plücker, and was developed into a powerful special method by Chasles and others. See GEOMETRY and CURVE.

Geometry, however, is not the only field for the synoptic treatment of manifoldness. This is obvious if we reflect that any magnitude whatever may be represented by a line; so that any function of not more than two elements may be represented by a geometrical construction and treated by any method applicable in geometry. Since the famous dissertation of Riemann, *On the Hypotheses that form the Basis of Geometry*, mathematicians have been familiar with the fact that the methods of geometry suitably generalized can be applied to the treatment of an $n$-fold manifoldness; and in point of fact the synoptic treatment of manifoldness under the name of $n$-dimensional geometry has been usefully employed by Cayley and others as an adjunct to the analytic method.

The fundamental characteristic of the analytical treatment of an $n$-fold manifoldness is the specification of an element by means of $n$ continuously varying quantities or variables (see MEASUREMENT). For dealing with continuous as distinguished from discrete quantity we have the special analytical method of the INFINITESIMAL CALCULUS (*q.v.*), built upon the notion of a limit, with its various branches, viz., the differential calculus, the integral calculus including differential equations, the calculus of functions, and the theory of functions in general (see FUNCTION). But, whether we make use of the algorithm of the infinitesimal calculus or not, we find upon examination that all analytical operations with continuous quantity fall under the three laws of commutation, association, and distribution, so that they are fundamentally identical with the operations with discrete quantity; the difference so far as there is any consists simply in the greater generality of the operand. The same fact may be looked at instructively in another light. Whether we consider analytical processes in concrete applications or look at them abstractly, we are equally led to the notion of a unit, by the multiplication or subdivision of which all the other quantities that enter into our calculus are derived. The exigencies of continuity are met by allowing that the multiplication or subdivision of the unit can be carried on to an unlimited extent; but in any case where analytical formulæ have to be reduced to arithmetical calculation (in which of course only a finite number of figures or arithmetical symbols can be used) the subdivision (or multiplication) of the unit actually stops short at a certain point; in other words, all our methods are, in practice at least, discrete. Here therefore we have the meeting point of discrete and continuous quantity, and on this ground alone we might infer the fundamental identity of their laws of operation.

The abstract science of quantity which we have just seen to be the essential part of the analytic treatment of manifoldness receives the name of ALGEBRA (*q.v.*). It was found very early in the history of that science that the full development of which it is capable could not be attained without great extension of the idea of quantity. This necessity first arose in connexion with the inverse operations, such as subtraction, the extraction of roots, and the numerical solution of algebraical equations (see EQUATION), of which root extraction is merely a particular case. In this way arose essentially negative quantities, and the so-called impossible or imaginary quantities. The former may be said to depend on a new abstract unit $-1$, and the latter upon new units $\pm\sqrt{-1}$. The numbers having $\pm 1$ for abstract unit are usually classed as real numbers, and in that case we may regard the ordinary imaginaries of algebra as depending on the new unit $+\sqrt{-1}$, or $\iota$, defined by the equation $\iota^2+1=0$. But the extension was soon carried farther by the classical researches of Hamilton and Grassmann.[1] The theory of sets and the QUATERNIONS (*q.v.*) of the former and the *Ausdehnungslehre* of the latter opened up a boundless field for algebra, and led to a total revolution in our ideas of quantity.

In view of the great extension thus effected in the meaning of quantity, it becomes an interesting if somewhat difficult undertaking to define the word. The following may be taken as a provisional definition:—*Quantity is that which is operated with according to fixed mutually consistent laws.* Both operator and operand must derive their meaning from the laws of operation. In the case of ordinary algebra these are the three laws already indicated, in the algebra of quaternions the same save the law of commutation for multiplication and division, and so on. It may be questioned whether this definition is sufficient, and it may be objected that it is vague; but the reader will do well to reflect that any definition must include the linear algebras of Peirce, the algebras of logic, and others that may be easily imagined, although they have not yet been developed. This general definition of quantity enables us to see how operators may be treated as quantities, and thus to understand the rationale of the so-called symbolical methods. In combining operations, it is often observed that the combinations of operators fall under a few simple laws, in some cases in fact under the three laws of ordinary algebra; these operators are therefore quantities according to the general definition, and can be treated as such.

From the historical development of the analytic method there is little danger of the error arising that its application is peculiar to any special kind of manifoldness. As examples of its use in deducing the properties of tridimensional space we may cite the Cartesian geometry, the *Géométrie de Position* of Carnot, and the line geometry of Plücker (see GEOMETRY). Its use in the various branches of applied mathematics, of which geometry is merely one of the simplest, is far more common than that of the

[1] In this connexion should be mentioned the great services of De Morgan, whose bold speculations on the fundamental principles of mathematical science have perhaps met with less than their due share of appreciation.

synoptic method, although most branches of applied mathematics are mixtures using the one or the other, as happens to be convenient. In addition to those already mentioned, we may enumerate the following as among the more important departments of applied mathematics:—Kinematics; Abstract Dynamics, including Statics and Kinetics whether of a Particle, of a Rigid Solid, of an Elastic Solid, of a Fluid, or of a Chain; Statistical Mathematics, as exemplified in the Theory of Annuities, and the Kinetic Theory of Gases; the Mathematical Theory of Diffusion whether of Heat or of Matter; the Theory of Potential; and so on. See MECHANICS, HYDROMECHANICS. ANNUITIES, HEAT, ELECTRICITY, MAGNETISM, &c.

The two great methods employed in the investigation of manifoldness must of course be, at bottom, identical; and every conclusion arrived at by the one must be reachable by the other. The exact nature of the connexion between them will be well seen by studying two instances. One of these is the treatment of areas by Euclid and the treatment by the analytical method, which are carefully compared in the article GEOMETRY, vol. x. p. 379. The other is the connexion between the descriptive and the metrical properties of loci. The former include all properties such as intersection, tangency, &c., depending on position merely, and are obviously the natural product of the synoptic method. The latter include all relations involving the lengths of lines and the magnitudes of angles, they depend therefore on expression in terms of a unit, and are the natural product of the analytic method. Nevertheless the analytic method furnishes descriptive properties of loci, and by the introduction of "the absolute" descriptive theorems are made to furnish metrical relations, as has been fully shown by Cayley, Clifford, and Klein (see MEASUREMENT). (G. CH.)

MATHER, COTTON (1663–1728), was the most learned and widely known of a family which through four generations enjoyed singular consideration, and exercised commanding influence upon New England in its first century. Richard, son of Thomas Mather of Lowton (Winwick), Lancashire, England, after studying for a time at Brasenose, Oxford, and teaching and subsequently preaching at Toxteth Park, went to New England, for nonconformity's sake, in the summer of 1635, where, till his death in 1669, at seventy-three, he was pastor of the Congregational church in Dorchester (now a part of Boston),—acquiring large repute, writing three or four instructive and constructive treatises upon polity, and being much trusted as to the foundations of both church and state. His youngest son Increase took his first degree at Harvard College in 1656, at seventeen,—returning, after a visit to the old country, in which he served several pulpits, to take at twenty-five the pastorate of the second (or North) church in Boston, which place he held till his death in 1723 at eighty-five, while, in addition, he had been acting, or actual, president of the college most of the time from 1681 to 1701, the author of one hundred and sixty books or tracts, and for four of its most perilous years the choice of all its citizens to represent the Massachusetts colony before the English Government. His wife Maria was daughter of the famous John Cotton, and their first-born received both family names, and when he took his B.A. degree at less than sixteen, at Harvard, in 1678, his promise tempted President Oakes to say in his presence, referring to his two distinguished grandfathers: "Cottonus atque Matherus tam re quam nomine coalescant et reviviscant." After a short time spent as tutor, and a period of diligent toil ending in the conquest of an impediment of speech which endangered success in the family profession, he became assistant to his father, in two years being ordained co-pastor, and holding the pulpit for nearly three and forty years, till his death at sixty-five. As a private Christian from his frank diaries, it is clear that he laboured much with himself, in a single year devoting more than sixty days to fasting and twenty nights to vigil. As a preacher he was conscientious and successful,—always diligently studying his discourses, in one year delivering more than seventy public sermons, with nearly half as many in private houses, sometimes thus "pressing a glorious Christ" through eleven successive days, and, with six competitors by his side, maintaining to the last his hold upon the largest congregation in New England, having about four hundred gifted communicants. As a pastor he was exceptionally laborious,—systematically exhorting and praying with his people at their homes, making conscience of spiritualizing every casual interview, and now and then spending days upon his knees with the names of his flock before him to prompt his intercessions for them, and for himself that he might better reach their peculiar need. As a philanthropist, while abundant in personal benefactions, he originated more than twenty societies for public charity, bore the cost of a school for Christianizing the negroes, and, at the risk of life, in the face of popular opposition medically led, advocated and vindicated the introduction of inoculation as a protection against the then terrible ravages of the small-pox. As an author he was learned—publishing in French, Spanish, and Algonkin as well as English—and voluminous, three hundred and eighty-two of his printed works having been catalogued, several of which are elaborate books, and one a folio of 800 pages; while his *Biblia Americana*, by him considered the great work of his life, remains in six huge volumes of manuscript to this day. As a scholar he was better known across the sea than any other American of his time, once contemporaneously corresponding with more than fifty learned Europeans, in his forty-seventh year being made doctor of divinity at Glasgow, and receiving election as a Fellow of the Royal Society—in those days eminent distinctions for a colonist. With all this it must be confessed that he had some grave defects. His common sense was not uniformly equal to his need. Always ambitious and self-opinioned, he was occasionally irritable and conceited. He lacked good taste, and it was his unconcealed grief that he was never elected to preside over Harvard College. His enormous knowledge did not digest well, and his use of learning tended to be crude. He was superstitious, and it was his misfortune that, as to witchcraft, he was not, as with vaccination, in advance of his generation, any more than such men as Richard Baxter and Sir Matthew Hale. Of his works the *Magnalia* and *Ratio Disciplinæ* are indispensable to the student of New England history.

MATHEW, THEOBALD (1790–1856), popularly known as Father Mathew, the "Apostle of Temperance," was descended from an illegitimate branch of the Llandaff family, and was born at Thomastown, Tipperary, on October 10, 1790. He received his school education at Kilkenny, whence he passed for a short time to Maynooth; from 1808 to 1814 he studied at Dublin, where in the latter year he was ordained to the priesthood. Having entered the Capuchin order, he, after a brief time of service at Kilkenny, joined the mission in Cork, which was the scene of his religious and benevolent labours for many years. The movement with which his name is most intimately associated began in 1838 with the establishment of a total abstinence association, which in less than nine months, thanks to his moral influence and eloquence, enrolled no fewer than 150,000 names. It rapidly spread to Limerick and elsewhere, and some idea of its popularity may be formed from the fact that at Nenagh 20,000 persons are said to have taken the pledge in one day, 100,000 at Galway in two days, and 70,000 in Dublin in five days.

In 1844 he visited Liverpool, Manchester, and London with almost equal success. Meanwhile the expenses of his enterprise had involved him in heavy liabilities, and led on one occasion to his arrest for debt; from this embarrassment he was only partially relieved by a pension of £300 granted by the queen in 1847. In 1849 he paid a visit to the United States, returning in 1851. He died at Queenstown on December 8, 1856. See *Father Mathew, a Biography*, by J. F. Maguire, M.P. (1863).

MATHEWS, Charles (1776–1835), comedian, was born in London, 28th June 1776. His father was what he called "a serious bookseller," and also officiated as minister in one of Lady Huntingdon's chapels. Mathews was educated at Merchant Taylors' School. His love for the stage was formed in his boyhood, partly from admiration of Elliston, with whom he had taken part in private theatricals. According to his own statement, it ripened into an "overpowering, all-absorbing passion," unfitting him for business when he became apprentice to his father, who at length, in 1794, unwillingly permitted him to enter on a theatrical engagement in Dublin. For several years Mathews had not only to content himself with the most thankless parts at an almost nominal salary, but his figure, at this period of life thin and ungainly, and the peculiar twist in his countenance generally awakened the unconcealed ridicule of the audience. In 1798 he obtained a conditional engagement from Tate Wilkinson at York. In 1802 Mathews began to play in London at the Haymarket, and from this time his professional career was an uninterrupted triumph. His special excellence as an actor consisted in his wonderful gift of mimicry, enabling him to grasp the minutest and most individual features of the character he represented. His sense of the purely ludicrous in all its varied phases was perhaps unequalled, and by his marvellous command of facial expression and of different tones and accents of voice he could, when he so willed, completely disguise his personality without even the smallest change of dress. The versatility and originality of his powers were, in public, best seen in his "At Homes," begun in the Lyceum Theatre in 1818, "which," according to Leigh Hunt, "for the richness and variety of his humour, were as good as half a dozen plays distilled." But it was in the social circle that he displayed the finest and rarest traits of genius, while his simple and truly kind-hearted disposition won him an affection and esteem which mere genius could not have purchased. From his infancy the health of Mathews had been uncertain, and the toils of his profession gradually undermined it. He died at Plymouth, of heart disease, 28th June 1835. See *Memoirs*, by Mrs Mathews, 4 vols., 1838–39.

MATHEWS, Charles James (1803–1878), comedian, son of the above, was born at Liverpool, 26th December 1803. After attending Merchant Taylors' School he was articled as pupil to an architect, and he continued nominally to follow this business till 1835. His first appearance on the stage was made at the Adelphi, London. In 1838 he married Madame Vestris, then lessee of the Olympic, but neither his management of this theatre, nor subsequently of Covent Garden, nor of the Lyceum, resulted in pecuniary advantage. As an actor, however, he held from the first an unrivalled place in his peculiar vein of light eccentric comedy. The inimitable easy grace of his manner, and the imperturbable solemnity with which he perpetrated his absurdities, never failed to charm and amuse; his humour was never broad, but always measured and restrained. His range of characters was exceptionally narrow, and he was wholly incapable of representing any form of strong passion. It was as the leading character in such plays as the *Game of Speculation*, *My Awful Dad*, *Cool as a Cucumber*, *Patter versus Clatter*, and *Little Toodlekins*, that he specially excelled. Mathews was one of the few English actors who have played in French successfully—his appearance at Paris in 1863 in a French version of *Cool as a Cucumber*, written by himself, being received with the utmost approbation. After reaching his sixty-sixth year, Mathews set out on a tour round the world, and on his return in 1872 he continued to prosecute his professional duties without interruption till within a few weeks of his death, on July 26, 1878. See *Life of Charles James Mathews*, edited by Charles Dickens, 2 vols., 1879.

MATILDA, countess of Tuscany (1046–1114), popularly known as the Great Countess, was born in 1046, of a race of nobles of Lombard descent. By the death of her father Boniface the Rich, duke and marquis of Tuscany, she was left, at eight years old, under the guardianship of her mother, Beatrice of Lorraine, heiress to a powerful state, including Tuscany, Liguria, part of Lombardy, Modena, and Ferrara. Her life was a protracted struggle against the schism which rent the church, under a series of antipopes, supported by a large section of the clergy and people of Italy and Germany, as well as by the whole strength of the empire. Against this formidable combination she maintained the cause of the holy see, often single-handed, for years, with varying fortune but undaunted resolution. The champion of several successive pontiffs, she is best known as the ally of Gregory VII., and her hereditary fief of Canossa was, in 1077, the scene of the celebrated penance of Henry IV. in presence of this pope. On the same occasion she made the donation, subsequently renewed in 1102, of her possessions to the holy see, in right of which the church owned the greater part of its temporal dominions. Matilda was twice married, first to Godfrey of Lorraine, surnamed the Humpbacked, son of her mother's second husband, and secondly to Guelph of Bavaria,—both marriages of policy, which counted for little in her life. She died of gout in 1114, in her sixty-ninth year, and was buried first at San Benedetto, and finally in the Vatican. Her steadfastness of purpose, strength of character, and loftiness of aim, made her one of the most striking figures even of the age which produced Robert Guiscard, William the Conqueror, Pope Hildebrand, and Godfrey of Bouillon, her nephew by marriage. The contemporary record of her life in rude Latin verse, by her chaplain Donnizone, is preserved in the Vatican Library.

An Italian biography was published in Lucca by Francesco Fiorentini in 1642 (new edition by Mansi, 1756), and one in French by Amédée Renée, *La Grande Italienne*, in 1859.

MATLOCK, a town of Derbyshire, England, is situated on the river Derwent and on the Midland Railway, 149 miles north-west of London and 17 north-west of Derby. It possesses cotton, corn, and paper mills, and in the vicinity there are lead-mines. About 1½ miles south-east, also on the Derwent, is Matlock Bath, possessing hot medicinal springs. There are in all three springs, the first of which was discovered in 1692. Their mean temperature is 68° Fahr., and applied both externally and internally the water is efficacious in glandular affections, rheumatism, biliary obstructions, and relaxation of the muscular fibres. The fine scenery of the vale of Matlock, and its proximity to the thickly peopled districts of Lancashire and Yorkshire, cause the village to be much frequented in summer not only by invalids but by holiday visitors. There are several large stalactite caverns. Matlock Bank, a mile to the north-east, in a finely sheltered situation, contains several well-known hydropathic establishments. The population of the urban sanitary district of Matlock (4513 acres) in 1871 was 3834, and in 1881 it was 4396; that of Matlock Bath and Scarthin Nick in the same years was 1386 and 1698. These two districts are conterminous with the civil parish of Matlock.

MATSYS, Quintin. See Massys.

MATTER, Properties of. If we knew thoroughly the nature of any piece of matter, the deduction of its properties would be a question of mere reasoning, just as (for instance) the definition of a circle really involves all the properties which mathematical methods have deduced from it. But, as we do not even know what matter is, in the abstract, the converse operation is (at least for the present) the natural and necessary one. We must endeavour from the experimentally ascertained properties of matter to discover what it is. The reader will find the limits of our present knowledge in the article Atom. The properties of matter may be arranged in several classes, thus :—

1. Properties of matter in itself; such as Inertia, Hardness, Brittleness, Elasticity (*q.v.*), Density, Compressibility, Viscosity, &c. These depend upon its ultimate structure and upon the law and intensity of the so-called molecular forces. See Atom, Constitution of Bodies, Attraction.

2. Relative properties of different kinds of matter, chemical, catalytic, &c. See Capillary Action, Chemistry, Diffusion, &c.

3. Properties relative to different forms of energy :— Conductivity (Thermal and Electric), Specific Gravity, Specific and Latent Heat, Transparency, Colour, Specific Inductive Capacity, Radiating and Absorbing Power, Magnetic Retentiveness, &c., Thermo-electric Position, Refractive Index, Reflective Power, Double Refraction, Rotatory Polarization, &c. These will be found mainly under the heads Electricity, Heat, Light, Magnetism, &c.

MATTEUCCI, Carlo (1811–1868), an Italian physicist, was born at Forlì, June 20, 1811. In 1832, after completing his studies at L'École Polytechnique, Paris, he became professor of physics at Bologna, where he had passed his earlier student days. In 1837 he removed to Ravenna, and in 1840 settled as professor of physics at Pisa. From 1847 he took an active part in politics, and in 1860 was chosen an Italian senator. At the same time he became general telegraph director, and later the superintendent of the meteorological bureaus. He died at Leghorn, June 25, 1868.

He is the author of four scientific treatises :—*Lezioni di fisica* (2 vols., Pisa, 1841 ; second edition 1851), *Lezioni sui fenomeni fisico-chimici dei corpi viventi* (Pisa, 1844; second edition 1846), *Manuale di telegrafia elettrica* (Pisa, 1850; and several later editions), and *Cours special sur l'induction, le magnetisme de rotation*, &c. (Paris, 1854). His numerous papers were published in the *Annales de Chimie et de Physique* (1829–58) ; and most of them also appeared at the time in the Italian scientific journals. They relate almost entirely to electrical phenomena, such as the magnetic rotation of light, the action of gas batteries, the effects of torsion on magnetism, the polarization of electrodes, &c., sufficiently complete accounts of which are given in Wiedemann's *Galvanismus*. Nine memoirs, entitled "Electro-Physiological Researches," were published in the *Philosophical Transactions*, 1845-60. See Bianchi's *Carlo Matteucci e l'Italia del suo tempo* (Rome, 1874).

MATTHEW (Μαθθαῖος or Ματθαῖος, *i.e.*, מַתִּי, a shortened form of Mattaniah or Mattithiah, equivalent to Theodorus; comp. vol. xi. p. 370), one of the twelve apostles of Jesus Christ, and, according to tradition, the author of the First Gospel. In its full Hebrew form the name occurs several times in the Old Testament, being borne by more than one person of priestly or Levitical family. Matthew, in the Gospel which bears his name, is described as having been a tax gatherer (τελώνης, Matt. x. 3), and the circumstances of his call to become a follower of Jesus, which he received as he sat at the "receipt of custom" or "tax office" in one of the towns by the Sea of Galilee, are briefly related in chap. ix. 9. It has sometimes been doubted, but without any good reason, whether the precisely parallel narrative relating to "Levi the son of Alphæus" (Mark. ii. 14; Luke v. 27, 28) has reference to the same person (compare the double names Simon and Peter, Joses and Barnabas, and others). In the lists of the names of the apostles given in the synoptical Gospels and in the Acts, Matthew ranks third or fourth in the second group of four. Little is recorded of him except the feast which he gave in his house at the beginning of his discipleship; the way in which this is related seems to indicate that he was (comparatively at least) a wealthy man. He was also present in "the upper room" at Jerusalem after the ascension, when Matthias was elected to be the successor of Judas. Tradition has nothing trustworthy to tell about his subsequent career, but there is nothing inherently improbable in the allegation of Eusebius (*H. E.*, iii. 24) that he spent several years in Jerusalem preaching to the Hebrews (and writing the Gospel which bears his name), or that he afterwards extended his missionary activities in other directions. Socrates (*H. E.*, i. 19) speaks of him as having carried the gospel to Ethiopia; the earlier legends, however, embodied in the apocryphal *Acta Andreæ et Matthæi* and *Acta et Martyrium Matthæi*, unanimously point to the regions bordering on the Black Sea ("Pontus" and the land of the Anthropophagi) as having been the scene of his labours (see the article of Lipsius on the "Apocryphal Acts of the Apostles" in Smith's *Dict. of Christ. Biog.*; also his *Apokr. Apostelgesch.*, 1883). According to the Gnostic Heracleon, whose statement is quoted and apparently homologated by Clement of Alexandria (*Strom.* iv. 9), Matthew died a natural death. He is commemorated as a martyr by the Greek Church on November 16, and by the Roman on September 21, the scene of his martyrdom being placed by the Breviary in "Ethiopia"; the same authority affirms that his body was afterwards translated to Salerno, where it now lies in the church built by Robert Guiscard. In Christian art (following Jerome) he is generally regarded as symbolized by the "man" in Ezek. i. 10, Rev. iv. 7.

MATTHEW, Gospel of. See Gospels, vol. x. p. 789 *sqq.*

MATTHEW of Paris, one of our most important writers in connexion with English mediæval history was born about the year 1200, or possibly somewhat earlier. His surname was probably derived either from his having been born in Paris or having studied in the university there; but his English origin is proved by the tone in which he uniformly speaks of foreigners, especially the French, while his knowledge of the French language is attested by the fact of his having written in that language, and also by the introduction of many French words in his Latin writings.

We have it on his own authority, as recorded in an autograph marginal note (MS. Cott., Nero, D. 1, fol. 165*b*), that he assumed the monastic habit at the abbey of St Alban's on the 21st of January 1217. In 1236 he accompanied the newly-elected prior of his abbey, John of Hertford, to London, to attend the ceremony of the nuptials of Henry III. and Eleanor of Provence; and in October 1247 he was at Westminster, in order to be present at the celebration of the feast of St Edward the Confessor, when he was desired by the king himself to write an account of the proceedings. The most important event in his tranquil and uneventful life (which was passed chiefly within the walls of his monastery) occurred in the year 1248, when he was sent on a mission to the Benedictine monastery of Holm (Throndhjem), which had become involved in difficulties owing to the maladministration of one of its abbots. He returned to England after more than a year's absence, and we can trace him as attending the royal court at Winchester in July 1251, and as present at York on the occasion of the marriage of Henry's daughter with Alexander II. of Scotland, some six months later. In March 1257 Henry himself visited St Alban's, and

remained at the monastery for a whole week. During this time he not only admitted Matthew to his table and to conversations in his private chamber, but also communicated to him facts and details of an historical character derived from his own personal knowledge and experience. Among other information, Matthew tells us that Henry repeated to him from memory the titles of the English baronies to the number of two hundred and fifty. The last incident recorded by the historian himself with respect to his own career is the fact that he exerted his influence with Henry on behalf of the university of Oxford, when that body found its privileges endangered by the encroachments of the bishop of Lincoln. In his latter years, Matthew's growing infirmities compelled him to have recourse to the aid of a fellow-monk in order to complete his works; this assistance is to be traced in the *Historia Anglorum* from 1252 to the end of the work (1253); in the *Abbreviatio Chronicorum* or the years 1253, 1254, and 1255; and in the *Chronica Majora* for the years 1258 and 1259. Matthew died after the month of May 1259, and his portrait, as he lay on his couch when dead, was drawn by his fellow-monk.

*Works.*—Matthew Paris's chief work, the *Historia Major*,—often styled the *Chronica Majora*,—is a narrative professing to record the outlines of human history from the creation, and terminating with the year 1259. It was long supposed that Roger of Wendover was the author of a much larger proportion of the work than was really the case; but the question may be regarded as finally set at rest by the decisive investigations and conclusions of Dr Luard, as stated at length in his prefaces to the volumes of his edition of the work in the Rolls Series. He concludes that the *Historia Major* down to the year 1189 was the work of John de Cella, abbot of St Alban's from the year 1195 to 1214; that it was then continued by Roger of Wendover on the same plan and from the same sources to the year 1235, the whole work down to this date passing for a long time as the production of the latter writer exclusively, and being known as the *Flores Historiarum*; that it was then transcribed by Matthew Paris, who, however, made numerous corrections and additions, but, in the opinion of Professor Stubbs, "interpreted" rather than "interpolated"; that it was then continued by the same writer, and is, from 1235 to the year 1259, exclusively his work. In style, in vividness of narration, and in descriptive power Matthew far excels his two predecessors. He is also entitled to the praise of having been a warm advocate of English rights and liberties, and a sturdy opponent alike of regal and papal tyranny; in fact, the national sentiment may be said first to receive adequate expression in his pages. The work, moreover, is not only the best source of information with respect to events in England during the reign of Henry III. down to the commencement of the Barons' Wars, but is also an authority with respect to Continental affairs, especially those of France and the empire.

The *Historia Anglorum* of Matthew is mainly an abridgment of his larger work,—the chief feature of difference being the omission of almost everything relating to foreign events. Sometimes, however, details and more particularly personal anecdotes are introduced, with many minute facts and circumstances which would be sought for in vain elsewhere, and largely illustrate contemporary usages and the general condition of society. Besides the above, Matthew wrote an *Abbreviatio Chronicorum*, extending from the year 1100 to 1255. Of this only one manuscript exists,—that in the author's own handwriting, preserved in the Cottonian collection in the British Museum, and printed in the third volume of the *Historia Anglorum*, edited by Sir Francis Madden. Matthew also compiled a *Liber Additamentorum* or *Supplementorum*, containing documents illustrative of the Greater Chronicle. This is contained in the folio edition of Matthew's writings edited by Wats, and published in 1640.

The *Vitæ viginti trium Abbatum S. Albani*, or *Lives of the Abbots of St Alban's*, does not bear Matthew's name, but is unquestionably the production of his pen. The biographies which belong to the period preceding the Norman Conquest contain valuable and interesting notices, but also include much of what is evidently fabulous. The *Vitæ duorum Offarum*, or *Lives of the two Offas*,—the one a mythical character, the other the historic monarch of Mercia,—is a composition of little value, and some doubt attaches to the authorship. Both the foregoing, however, are included in the edition by Wats.

*Editions.*—The best edition of the *Historia Major* is that by Dr Luard, published in five volumes in the Rolls Series, 1872–80. Of the *Historia Minor* an edition in three volumes in the same series was edited by Sir Frederic Madden, 1866–69. (J. B. M.)

MATTHIAS (1557–1619), holy Roman emperor, the fourth son of the emperor Maximilian II., was born on the 24th of February 1557. He was educated in Germany by the diplomatist Busbecq, while his brother, afterwards the emperor Rudolph II., was trained at the court of Philip II. of Spain. In 1577 Matthias went secretly to the Netherlands, the sovereignty of which he unlawfully assumed; but in 1580 he was compelled to withdraw into private life. He was vain, restless, and ambitious, and intrigued incessantly against the emperor Rudolph, a man of weak character, with a constitutional tendency to insanity. Rudolph passed wholly under the dominion of the Jesuits, and this rendered it easy for Matthias to stir up his Protestant subjects against him. In 1595 Matthias was made regent in Austria, and in 1606 the archdukes recognized him as head of the house of Hapsburg. Rudolph had to relax his hold over one country after another, and in 1611 Matthias was ruler of Hungary, Moravia, Silesia, Lusatia, and even Bohemia, whose loyalty the emperor had tried to secure by many concessions, especially by the letter of majesty granting religious freedom to Protestant sects. In 1612, after the death of Rudolph, Matthias was elected emperor; and his reign was not less disturbed than that of his predecessor. The intervention of Turkey in Transylvania led to war, and in 1615 Matthias, being unsupported by the empire and by his own estates, found that he had no alternative but to conclude peace for twenty years on humiliating terms. Protestants and Catholics, bitterly hating each other, formed respectively the Union and the League; and the rising power of the archduke Ferdinand, afterwards emperor, a bigoted prince who became king of Bohemia in 1617 and king of Hungary in 1618, indicated that even more serious troubles were approaching than those with which Rudolph had contended. In the last two years of the reign of Matthias, the Bohemians having rebelled, the first blows in the Thirty Years' War were struck. He died on the 20th of March 1619.

MATTHIAS CORVINUS (1443–1490), king of Hungary, was born at Klausenburg in Transylvania on March 27, 1443, and died at Vienna on April 6, 1490. He was the younger son of John Hunyady (Corvinus) who died in 1456 after having been "governor of Hungary" from 1446 to 1453. On the death of John, the elder of his two sons (Ladislaus) was executed by command of Ladislaus Posthumus, while Matthias was imprisoned at Prague; but shortly after the king's own death without issue in 1457, Matthias Hunyady (Corvinus) was elected by the Hungarian magnates to the vacant throne (January 24, 1458). The leading events of his reign are summarized in the article HUNGARY (vol. xii. p. 368, 369).

MATTING. Under this name are embraced many coarse woven or plaited fibrous materials used for covering floors or furniture, for hanging as screens, for wrapping up heavy merchandise, and for other miscellaneous purposes. In the United Kingdom, under the name of "coir" matting a large amount of a coarse kind of carpet is made from cocoa-nut fibre; and the same material, as well as strips of cane, Manila hemp, various grasses and rushes, is largely employed in various forms for making door mats. Perforated and otherwise prepared india-rubber is also largely utilized for door and floor mats. Matting of various kinds is very extensively employed throughout India for floor coverings, the bottoms of bedsteads, fans and fly-flaps, &c.; and a considerable export trade in such manufactures is carried on. The materials used are numerous; but the principal substances are straw, the bulrushes *Typha elephantina* and *T. angustifolia*, leaves of the date palm (*Phœnix sylvestris*), of the dwarf palm (*Chamærops Ritchiana*), of the Palmyra palm (*Borassus flabelliformis*), of the cocoa-

nut palm (*Cocos nucifera*), and of the screw pine (*Pandanus odoratissimus*), the munja or munj grass (*Saccharum Munja*) and allied grasses, and the mat grasses *Cyperus textilis* and *C. Pangorei*, from the last of which the well-known Palghat mats of the Madras Presidency are made. Many of these Indian grass mats are admirable examples of elegant design, and the colours in which they are woven are rich, harmonious, and effective in the highest degree. Vast quantities of coarse matting used for packing furniture, heavy and coarse goods, and plants, &c., are made in Russia from the bast or inner bark of the lime tree. This industry centres in the great forest governments of Viatka, Nijni-Novgorod, Kostroma, Kazan, Perm, and Simbirsk.

MATTOON, a city of the United States, in Coles county, Illinois, 172 miles south-south-west of Chicago, on the Central Illinois Railroad, which at that point intersects the Indianapolis and St Louis and the Peoria, Decatur, and Evansville Railroads. It had 5742 inhabitants in 1880, has railway carriage works and repair shops, and is rising rapidly in commercial importance.

MATURIN, Charles Robert (1782–1824), novelist and dramatist, perplexed the serious and served as a butt for the more light-minded critics of the first quarter of the 19th century. The bombastic extravagance of his language, the incoherence of his plots, the wild improbability of many of his incidents, the inconsistency of his characters, were obvious and undeniable; but there were so many passages of extraordinary eloquence in his novels, especially in his descriptions of turbulent passion, that, though some pronounced him evidently mad, all admitted that it was a madness allied to genius. At first he published only sermons in his own name, being curate of St Peter's, Dublin. His first novels, *The Fatal Revenge* (1804), *The Wild Irish Boy* (1808), *The Milesian Chief* (1811), were issued under the pseudonym of Dennis Jasper Murphy. All these were mercilessly ridiculed by the press and neglected by the public, but the irregular power displayed in them attracted the notice of some social and literary magnates; and through the influence of Byron and Scott Maturin's tragedy of *Bertram* was produced at Drury Lane in 1816, with a prologue by Hobhouse, an epilogue by the Hon. George Lamb, and with Kean and Miss Kelly in the leading parts. The magnificent scenic situations, and the character of Bertram (like one of Byron's sombre heroes), make this an effective stage play. It was the first and only success of the author; he returned to "the baffled efforts and the blighted hopes" of which Hobhouse speaks in his prologue. Two more tragedies, *Manuel* (1817) and *Fredolpho* (1819), were failures. A poem, *The Universe* (1821), fell flat. Three novels, *Women* (1818), *Melmoth* (1820), and *The Albigenses* (1824), produced a considerable impression. In the preface to *Women* he admitted that his previous novels had been justly condemned, being an impossible attempt to revive the exploded style of Mrs Radcliffe, and promised that he would enter on a new vein. But he could not alter his character. The new vein was as wild, fantastic, incoherent, interspersed with passages of really splendid eloquence, as the old. The *Albigenses* was to be the first of a series of historical romances, illustrating periods of European history, and it was noticed in the *Westminster Review* as giving, with all its faults, promise of better things; but the author died in the year of its publication.

MAUBEUGE, a fortified place of northern France, situated on both banks of the Sambre, 142 miles by rail north-east from Paris, and about 2 miles from the Belgian frontier. Its fortifications were planned by Vauban; the enceinte is pierced by two gateways, that of France and that of Mons. Maubeuge, besides containing an arsenal and several old convents, is an industrial town, manufacturing swords, files, axles, tools, hardware, machinery, porcelain tiles, and paper; in the neighbourhood there are numerous forges. The population in 1876 was 14,400.

Maubeuge owes its origin to a double monastery for men and women founded in the 7th century by St Aldegonde. It was burnt by the Normans, by Louis XI., by Francis I., and by Henry II., and was finally assigned to France by the treaty of Nimeguen. It was fortified by Vauban at the command of Louis XIV., who first saw military service there, under Turenne. Besieged in 1793 by the prince of Coburg, it was relieved by the victory of Wattignies. It was unsuccessfully besieged by the duke of Saxe-Weimar in 1814, but was compelled to capitulate, after a vigorous resistance, in the following year.

MAULMAIN, or Moulmein, a town in Amherst district, British Burmah, situated on the left bank of the Salwín river, in 16° 30′ N. lat. and 97° 38′ E. long. At the time of the cession of this part of the province to the British in 1826, Maulmain was a mere waste. It has now developed into a thriving commercial town, ranking next to Rangoon in importance, with a rapidly increasing population and trade. The population, which in 1857 was 23,683, had increased in 1872 to 46,472, and in 1881 to 53,107 (32,895 males and 20,212 females). The principal buildings are Salwín House, originally a private residence, but now the property of the municipality, the hospital, the jail, Protestant and Roman Catholic churches, the custom-house, and other public offices, and the barracks for the garrison of Madras native infantry. For many years timber formed the only export, but with the gradual settlement of the country and increase in agriculture rice and cotton began to be also exported; besides these, the other staple exports are hides, horns, lead, copper, yellow orpiment, and stick-lac. The principal imports are cotton twist and cloth, woollen piece-goods, wines and spirits, sugar, and betel-nuts. In 1880–81 573 vessels (266,010 tons) entered the port, and 536 (265,147 tons) cleared. The value of merchandise imported was £666,810, of treasure £312,190, of merchandise exported £1,389,763, and of treasure £92,817. Shipbuilding forms an important industry of the town.

MAUNDY THURSDAY, the day preceding Good Friday. The word "maundy" (Middle-English, *maundee* or *maunde*, a command) is identical with the "mandatum" of the rubric and anthem of the Missal for the fifth day in Holy Week, sometimes called "Dies Mandati" (see this shown at length by Skeat in *Etym. Dict.*, and in note to *Piers Plowman*, xvi. 140). The "mandatum" or "maund" referred to is the "new commandment" of John xiii. 34, but more particularly the precept given to the disciples in the same chapter "to wash one another's feet." The practice by prelates and others of literally and formally carrying out this injunction in a public manner on a given day has long been established both in the East and in the West. Perhaps an indication of it may be discerned as early as the 4th century in a custom, current in Spain, northern Italy, and elsewhere, of washing the feet of the catechumens towards the end of Lent before their baptism; it was not, however, universal, and in the 48th canon of the synod of Elvira (306 A.D.) it is expressly prohibited (comp. *Corp. Jur. Can.*, c. 104, caus. i. qu. 1). Be this as it may, the "pedilavium," or ceremony of washing the feet of twelve beggars on this day, has now for centuries been observed by the prelates of the Church of Rome, including the pope himself, according to a ritual minutely prescribed in the Missal; it is also practised by the Austrian emperor, the king of Bavaria, and other European sovereigns in the Latin obedience, as well as by the emperor of Russia and others at the head of the Greek Church. In England it was continued by the sovereign even after the Reformation; the last recorded instance of its full performance is in the case of James II., but a distribution of royal alms, consisting of money and clothing,

is still continued. It is on Maundy Thursday also that in the Church of Rome the sacred oil is blessed, and the chrism prepared, according to an elaborate ritual which is given in the *Pontificale*.

MAUPERTUIS, Peter Louis Moreau de (1698–1759), a mathematician and astronomer of considerable reputation in his day, was born at St Malo, July 17, 1698. When twenty years of age he entered the army, becoming lieutenant in a regiment of cavalry, and employing his leisure on mathematical studies. After five years he quitted the army and was admitted in 1723 a member of the academy of sciences. In 1728 he visited London, and was elected a fellow of the Royal Society. In 1736 he acted as chief of the expedition sent by Louis XV. into Lapland to measure the length of a degree of the meridian within the polar circle, in order to settle the then much disputed question of the oblate figure of the earth, and, on his return home, he became a member of almost all the scientific societies of Europe. In 1740 Maupertuis went to Berlin on the invitation of the king of Prussia, and took part in the battle of Mollwitz, where he was taken prisoner by the Austrians. On his release he returned to Berlin, and thence to Paris, where he was elected director of the academy of sciences in 1742, and in the following year was admitted into the Academy. Returning to Berlin in 1744, Maupertuis married a lady of rank and great beauty, and in 1746 was chosen president of the royal academy of sciences. Finding his health declining, he repaired in 1757 to the south of France, but went in 1758 to Basel, where he died July 27, 1759. Maupertuis was unquestionably a man of considerable ability as a mathematician, but his restless, gloomy disposition involved him in constant quarrels, of which his controversies with König and Voltaire during the latter part of his life furnish examples.

The following are his most important works:—*Essay on Cosmology*; *Discourse on the Different Figures of the Stars*; *Essay on Moral Philosophy*; *Philosophical Reflexions*, &c.; *Animal Physics*; *System of Nature*; *Elements of Geography*; *Account of the Expedition to the Polar Circle*, &c.; *Laws of Motion*; *Laws of Rest*; *Parallax of the Moon*; *The Comet of* 1742; *On the Progress of the Sciences*. He also contributed a large number of interesting papers to the *Memoirs* of the academies of Paris and Berlin.

MAU RÁNÍPUR, a town in Jhánsí district, in the North-Western Provinces of India, in 25° 15′ N. lat., 79° 11′ E. long. The population in 1872 was 16,428. Although now a large trading centre, the town is of quite modern commercial importance, having risen from the position of a small agricultural village through the influx of merchants seeking relief from extortionate demands made by the rájá of a neighbouring native state. It contains a large community of wealthy merchants and bankers. A special variety of cloth, known as *kharna*, is manufactured and exported to all parts of India. The principal imports are sugar, English piece-goods, silk, metals, and coffee. Trees line many of the streets, and handsome temples ornament the town.

MAURER, Georg Ludwig von (1790–1872), a distinguished German jurist and statesman, was born at Erpolsheim in the Bavarian Palatinate, November 2, 1790. He was the son of a Protestant pastor. He received his education at the university of Heidelberg, and afterwards followed for some time the profession of an advocate. In 1812 he went to reside in Paris, where, with the aid of the great libraries of that city, he entered on a systematic study of the ancient legal institutions of Germany. On his return to Bavaria he was appointed substitute for the attorney-general in the district of Spires and Landau. In 1824 he published at Heidelberg his first work, *Geschichte des alt-germanischen und namentlich alt-bairischen öffentlich-mündlichen Gerichtsverfahren*, which obtained the first prize of the academy of Munich. In 1826 he was made one of the professors of law in the university of Munich. In 1832, Otho, son of King Louis of Bavaria, having been chosen to fill the throne of Greece, a council of regency was nominated to conduct the government of that country during his minority. Of this council Von Maurer was appointed a member, the others being the Count von Armansperg, who was president, Major-General K. W. von Heideck, and K. von Abel. They applied themselves energetically, and at first apparently in a spirit of concord, to the task of creating for the new kingdom institutions adapted to the requirements of a modern civilized community. But grave differences soon made themselves felt, Maurer being at variance with the president on important administrative questions. These being referred to King Louis, he decided in favour of the president, and Maurer and Abel were suddenly recalled in 1834. The loss of Maurer was a serious one for Greece; he was the ablest, most energetic, and most liberal-minded member of the regency, and had already done important work in the juridical and educational organization of the kingdom. It was through his enlightened efforts that Greece had obtained a revised penal code, regular tribunals, and an improved system of civil procedure. Soon after his recall, he published his work entitled *Das griechische Volk in öffentlicher, kirchlicher, und privatrechtlicher Beziehung vor und nach dem Freiheitskampfe bis zum* 31 *Juli* 1834 (3 vols., Heidelberg, 1835–36). This book is a valuable source of information on the history of Greece during the preceding years, its condition before the call of Otho to the throne, and the labours of the council of regency down to the time of the author's recall. Notwithstanding his removal from office, he does not appear to have forfeited the esteem or goodwill of King Louis. After the fall of the ultramontane ministry of Abel in 1847, he became minister of foreign affairs and of justice, but on attempting to carry out reforms he was overthrown; retiring then from political life, he devoted himself altogether to historical and juristic studies, the fruits of which he gave to the world in successive publications. He died at Munich, May 9, 1872.

The following is believed to be a complete list of such of his writings as have not been already mentioned:—*Grundriss des deutschen Privatrechts*, 1828; *Ueber die bairischen Städte und ihre Verfassung unter der römischen und fränkischen Herrschaft*, 1829; *Ueber die deutsche Reichsterritorial- und Rechtsgeschichte*, 1830; *Das Stadt- und das Landrechtsbuch Ruprechts von Freising nach 5 münchener Handschriften, ein Beitrag zur Geschichte des Schwabenspiegels*, 1839; *Ueber die Freipflege* (plegium liberale), *und die Entstehung der grossen und kleinen Jury in England*, 1848; *Einleitung zur Geschichte der Mark-, Hof-, Dorf-, und Stadt-Verfassung und der öffentlichen Gewalt*, 1854; *Geschichte der Marken-Verfassung in Deutschland*, 1856; *Rede bei der* 100-*jährigen Stiftungsfeier der K. Akademie der Wissenschaften am* 28 *März*, 1859; *Geschichte der Dorf-Verfassung in Deutschland*, 2 vols., 1865–66; *Geschichte der Fronhöfe, der Bauernhöfe, und der Hofverfassung in Deutschland*, 4 vols., 1862–63; *Geschichte der Städ-Verfassung in Deutschland*, 4 vols., 1869–71. He also superintended the preparation of a part of the continuation of Jacob Grimm's *Weisthümer*, published under the auspices of the academy of Munich, 1866. His researches on the ancient village communities of Germany are of special interest and importance.

MAURETANIA, or Mauritania (the former is the more correct form of the name, according to coins and inscriptions), was the name given in ancient geography to the district which constituted the north-western angle of the African continent. It comprised a considerable part of the modern empire of Morocco, together with the western portion of Algeria. But its limits varied much at different times. When it first appears in history the river Mulucha constituted its eastern limit, which separated it from the Numidian tribe of the Massyli, who held all the country from that river to the Ampsaga; but at a later period the kingdom of Mauretania was extended to the

latter river so as to include the whole territory from the Ampsaga to the Atlantic Ocean. Towards the south it was bounded by the great range of Mount Atlas, and it appears to have been regarded by geographers as extending along the coast of the Atlantic as far as the point where that chain descends to the sea, in about 30° N. lat., though the Roman province of the name extended but a little beyond Sala (Sallee), and it is probable that there were no towns or permanent settlements farther south. The magnificent plain, or rather plateau, in which the city of Morocco is situated seems to have been unknown to ancient geographers, and was certainly never included in the Roman empire. On the other hand the Gætulians, who inhabited the narrow strip of fertile date-producing territory on the southern slopes of the Atlas, though not included under the name of Mauretania, seem to have always owned a precarious subjection to the kings of that country, and in after days to its Roman governors.

The physical geography of the country will be described under the heading MOROCCO, though it must be observed that the term Mauretania, as used by the Romans, comprised also the greater portion of the French colony of Algeria, including the provinces of Oran and Algiers, and even a part of that of Constantine. The range of Mount Atlas forms throughout the backbone of the country, from which the streams descend to the Mediterranean and the ocean. The most important of those on the north coast is the Mulucha or Molochath, which in the earliest times constituted the eastern limit of the country; it is still called Muluya. Farther east are the Chinala, the Usar, and the Ampsaga. Of those that flow westward towards the Atlantic, the most considerable were the Lixus, Subur, and Sala. But from the proximity of the mountain ranges to the sea none of these streams were of any importance, or navigable beyond a short distance from the sea.

A large part of the country is of great natural fertility, and was in ancient times extensively cultivated, and produced large quantities of corn, while the slopes of Mount Atlas were clothed with vast forests, which, besides other kinds of timber, supplied the celebrated ornamental wood called *Citrus*, for tables of which the Romans gave such fabulous prices.

Mauretania, or Maurusia, as it was called by Greek writers, unquestionably signified the land of the Mauri, a term still retained in the modern name of Moors, and probably meaning originally nothing but "black men." The origin and ethnical affinities of the race are unknown; but it is probable that the inhabitants of all this northern tract of Africa along the coast of the Mediterranean were kindred races belonging to the family which is represented at the present day by the Berbers of the mountain districts and the Tuaricks of the tract south of the Atlas. They first appear in history at the time of the Jugurthine War (110–106 B.C.), when Mauretania west of the Mulucha was under the government of a king called Bocchus, and appears to have constituted a regular and organized state. It retained its independence till the time of Augustus, who in 25 B.C. bestowed the sovereignty of the previously existing kingdom upon Juba II., king of Numidia, at the same time uniting with it the western portion of Numidia, from the Mulucha to the Ampsaga, which now received the name of Mauretania Cæsariensis, while the province that had previously constituted the kingdom, or Mauretania Proper, came to be known as Mauretania Tingitana. This distinction continued to subsist after the incorporation of the two provinces in the Roman empire under Claudius in 42 A.D., and remained unchanged till the time of Constantine.

In the time of Pliny and Ptolemy, Mauretania contained a number of flourishing cities and towns, several of which enjoyed the privileges of Roman colonies, having been founded no doubt in great part with a view of keeping in check the wild barbarians who still occupied the greater part of the country. The most important of these places were—Tingis, on the site of the modern Tangier, the capital of the province to which it gave its name; Lixus and Sala, on the coast of the Atlantic, at the mouths of the rivers of the same name; and three towns in the interior of the same province, Zilis, Babba, and Banasa, all of them bearing the title of Roman colonies. On the coast of the Mediterranean stood Rusaddir (now Melilla), within the limits of Tingitana; and beyond the Mulucha Cartenna (now Tenes); Iol, surnamed Cæsarea, which was made his capital by Juba II., and continued to be that of Mauretania Cæsariensis under the Romans (its site is now called Cherchell); Icosium (the modern Algiers); Saldæ (Bujeyah); Igilgili (Jijeli) near the eastern limit of the province; and Sitifis (Setif) at no great distance in the interior, a town of considerable importance, which after the time of Constantine gave the name of Mauretania Sitifensis to this eastern portion of the province. The prosperity of this part of Africa under the Roman empire, previous to the irruption of the Vandals in 429 A.D., is shown by the fact that no less than one hundred and seventy towns which were episcopal sees are enumerated in the Notitia in the two provinces of Mauretania.

MAURICE (MAURICIUS), ST, and his companions are commemorated as martyrs by the Roman Church on September 22. The earliest extant form of the legend relating to them is that of Eucherius, bishop of Lyons about the middle of the 5th century, who tells us that Maurice was in command of the Theban legion (so called because raised in the Thebais) when it was sent into the West and attached to the army of Maximian. Themselves Christians to a man, its members refused to persecute their coreligionists, and for this, after having twice been decimated, the legion was utterly destroyed by command of the emperor at Octodurum (Martigny) near Geneva. A later form of the legend connects it with the expedition of Maximian against the Bagaudæ, who are taken to have been Christians; the martyrdom of the legion arises out of its refusal to take part in a great sacrifice which had been ordered at Octodurum; and another name—that of Exsuperius—is associated with Maurice's. Later still, Gregory of Tours knows of a company of the same legion which suffered at Cologne (their leader subsequently became known as Gereon). The date usually assigned to the martyrdom of the Theban legion is 286 A.D.; but it is matter of history that at that period the Christians were everywhere unmolested in the exercise of their religion throughout the Roman empire. On the other hand, at no later date have we any evidence of the presence of Maximian in the Valais; and, apart from the great *a priori* improbability of the extirpation of a whole legion under any circumstances on account of its Christian profession, it is practically impossible to get over the fact that such writers as Eusebius, Lactantius, Orosius, and Sulpicius Severus know nothing of such a noteworthy and startling event having taken place. But in the long and voluminous controversy as to the historical character of this legend it has of course never been attempted to deny that isolated cases of officers being put to death on account of their religion occurred during the reign of Maximian. The cultus of St Maurice and other members of the Theban legion occurs chiefly in Switzerland, the region of the Rhine, and northern Italy; the foundation of the abbey of St Maurice (Agaunum) in the Valais is usually ascribed to Sigismund of Burgundy (515).

MAURICE (MAURICIUS FLAVIUS TIBERIUS), emperor of the East from 582 to 602, was of Roman descent but a native of Arabissus in Cappadocia, where he was born about 539. He spent his youth at the court of Justin II., and, having joined the army, fought with distinction in the Persian war (578–581). At the age of forty-three he was declared Cæsar by the dying emperor Tiberius II., who bestowed upon him the hand of his daughter Constantina. In the meagre annals of the reign of Maurice the most conspicuous events are the termination of the long struggle in the East with the restoration to the Persian throne of Chosroes II. by the Roman general Narses (not the conqueror of Italy) in 591, and the successes of Priscus in the protracted war against the Avars. Some inopportune attempts at army reform, and an ill-judged refusal to provide a ransom which might have prevented the massacre of twelve thousand prisoners in the hands of the enemy, led to a rebellion

among the legions on the Danube, who declared Maurice unworthy to reign, and, commanded by Phocas, then a simple centurion, but destined to become emperor, marched upon Constantinople. The capital having declared against him, Maurice abdicated and withdrew to Chalcedon, but was pursued and put to death there after having witnessed the murder of five of his sons (November 27, 602). He was the author of a work on military art (στρατηγικά) in twelve books, of which there is an edition by Scheffer, published at Upsala in 1664. There is a *Vita Mauricii* by Theophylact Simocatta.

MAURICE OF NASSAU, prince of Orange, the younger son of William the Silent, was born at Dillenburg in 1567, and was made governor of the United Provinces after the assassination of his father in 1584. He succeeded his brother as prince of Orange in 1618, and died at the Hague on April 23, 1625. For the leading features of his character and events of his life see HOLLAND, vol. xii. pp. 77, 78.

MAURICE (1521–1553), duke and elector of Saxony, the son of Duke Henry the Pious, was born on the 21st of March 1521. He received a learned education, and at an early age gave evidence of an energetic and ambitious temper. In 1541 he married Agnes, daughter of the landgrave Philip of Hesse, and succeeded his father as duke of Saxony, of the Albertine line. Although a Protestant, he held cautiously aloof from the League of Smalkald; and in 1542 and 1543 he received imperial favour by supporting Charles V. against the Turks and the French. In 1546, when Charles V. attacked the League of Smalkald, Maurice sided with the emperor, the result being that he was made elector of Saxony in place of his cousin John Frederick (of the Ernestine line), who was taken prisoner and deposed. At this time Maurice was detested by the German Protestants, who considered him a traitor to his religion; but the tide soon turned. Fearing that the emperor's ultimate aim was to strike at the authority of the princes, he began silently to make preparations for war; and Charles V. was imprudent enough to provide him with a pretext for opposition by detaining the landgrave Philip of Hesse, whose freedom Maurice had guaranteed. In 1551 Maurice concluded a secret treaty with Henry II. of France against the emperor, and an alliance was also formed with several German princes. Charles V. refused to believe in the reality of the danger; but in March 1552 he was startled by the intelligence that Henry II. had entered Germany as an invader, and that Maurice was hastening southward at the head of a powerful army. John Frederick and Philip were at once released, and the emperor, after an ignominious flight, was compelled to sign the treaty of Passau. After the re-establishment of peace Maurice fought for some time against the Turks in Hungary; he then returned to Saxony, and associated himself with the alliance against Margrave Albert of Brandenburg, by whom the treaty of Passau had not been recognized. At Sievershausen, on the 9th of July 1553, the margrave was defeated; but during the battle Maurice was wounded, and two days afterwards he died in his tent. He was not only a great diplomatist and general, but one of the most enlightened rulers of his age, and his early death was sincerely deplored by his subjects. In his last years he was content "with small diet and little sleep." "Therefore," says Roger Ascham, who had seen him, "he had a waking and working head, and became so witty and secret, so hardy and ware, so skilful of ways, both to do harm to others and to keep hurt from himself, as he never took enterprise in hand wherein he put not his adversary always to the worse."

See Roger Ascham, *A Report and Discourse of the Affairs and State of Germany*; Langenn, *Moritz, Herzog und Kurfürst von Sachsen*, 1841; G. Voigt, *Moritz von Sachsen* 1541–47, 1876.

MAURICE, JOHN FREDERIC DENISON (1805–1872), better known without his first name, an English clergyman and theologian, was born in the year 1805. He was the son of a Unitarian minister, and educated in his father's faith, entering Trinity College, Cambridge, as a Nonconformist, for the sake of the university course, at a time when it was impossible for any but members of the Established Church to obtain a degree. Together with John Sterling, Maurice migrated to the smaller college of Trinity Hall, whence he obtained a first class in civil law in 1827; he then came to London, and gave himself to literary work, editing for a short time the *Athenæum* newspaper. During this period of his life he came under the influence of S. T. Coleridge,—an influence which drew Maurice into conformity, and issued through him in what was known as the Broad-Church school of thought.

When Maurice joined the Church of England, he might no doubt have returned to Cambridge for his degree, or, when he chose Oxford, his terms at Cambridge would have been allowed him, but with characteristic thoroughness he elected to go through the whole Oxford course. He entered Exeter College, and obtained a second class in classics in 1831.

The intellectual stir of Oxford life, and the vehement controversies in the clash of which sparks of truth seemed struck out, were probably among the causes which attracted Maurice to Oxford, and he afterwards took his full share in them, always in a liberal, tolerant, yet strongly Protestant spirit. He was ordained in 1834, and after a short interval spent in parish work in the country was appointed chaplain of Guy's Hospital, and became thenceforward a sensible factor in the intellectual and social life of London. Carlyle has told us how "going to Guy's" Sunday after Sunday was a part of Sterling's routine, and an appreciable number of persons far above the average were attracted to the hospital chapel. In 1840 Maurice was appointed professor of history and literature in King's College, to which in 1846 was added the chair of divinity. These chairs he held till 1853. In that year he published *Theological Essays*, wherein were stated opinions which savoured, to the principal, Dr Jelf, and to the council, of unsound theology in regard to eternal punishment. Maurice maintained with great warmth of conviction that his views were in close accordance with Scripture and the Anglican standards, but the council ruled otherwise, and he was deprived of his professorships. He held at the same time the chaplaincy of Lincoln's Inn (1846–60), but no attempt was made to deprive him of this. Neither was he assailed in the incumbency of St Peter's, Vere Street, which he held for nine years (1860–69), and where, though his congregation was never large, partly perhaps because no parish or district was apportioned to his church, he drew round him a circle of thoughtful persons, attached in no common degree to himself and to his teaching.

During his residence in London Maurice was specially identified with two important movements for education, the Working Men's College, and Queen's College for the education of women, while he threw himself with great energy into all that affected the social life of the people. Certain abortive efforts at a true co-operation among working men, and the movement known as Christian Socialism, were the immediate outcome of his teaching, and directly fostered by himself. In 1866 Maurice was appointed professor of moral philosophy in the university of Cambridge. He died on the 1st of April 1872.

Maurice was before all things a preacher. The actual message he had to proclaim was apparently simple; his two great convictions, which he strove to impress on all other men, were the fatherhood of God, and that all religious systems which had any stability lasted because of a portion of truth which had to be disentangled from the error differentiating them from the doctrines

of the Church of England as understood by himself. His love to God as his Father was a passionate adoration which filled his whole heart. No one who ever heard Maurice read the Lord's Prayer can possibly forget it; the intensity of his convictions in the pulpit made his message seem as luminous and clear as it was brief and concentrated, though his teaching apart from the living voice had by no means the same character.

It was the peculiarity of his congregation that those who wanted his advice sought him; having no parish, he had no definite sphere of work beyond the church. Thus his preaching took the forms now of exposition and now of the resolution of metaphysical difficulties, rather than of direct dealing with the facts, the sins, and the temptations of human life common to all. Feeling this defect, he took for a time a district for parochial visitation, but was perplexed and distressed at the experience to which he was unequal. With all his affectionateness and desire to give sympathy he was unable even to conceive intellectual difficulties which were not his own. To those who did not demand of him all they needed, but took thankfully what he had to give, he was altogether a stimulating and helpful teacher. He opened new views, and encouraged men to think for themselves, and see what their words meant. He was even morbidly fearful of founding a party, and was deeply distressed at the name Broad-Church. Those who surrounded him, and were kept together by his personal charm and influence, were learning to think for themselves, and have dispersed in many directions. There are probably not half a dozen persons who, even nominally, reflect the precise shades of Maurician teaching.

As a writer it is extremely doubtful if his work will have a great and permanent place in the future. His one novel, *Eustace Conway*, is even now unread; his theological works, though abounding in passages of great beauty, full now and then of a fiery eloquence, are as a whole somewhat obscure. He published too much, and a large number of his works are sermons recast. We miss the human voice, and we find a class of writing which only the highest excellence can make tolerable out of the pulpit.

Maurice's greatest effect on his time is in his educational work. The Working Men's College, which owes more to him than to any one else, for which he rendered great sacrifices, and which was and is more full of his spirit than are most institutions of that of their founders, was a totally new departure in education. It was intended to give, and it has largely succeeded in giving, not what is called a popular education, but "higher education" to working men, and in combining teachers and taught in a college with its social life, and a bond of common interests. Queen's College, in like manner for the higher education of girls, is scarcely less identified with his life, though its influence is not so great, nor can its work be so widely known.

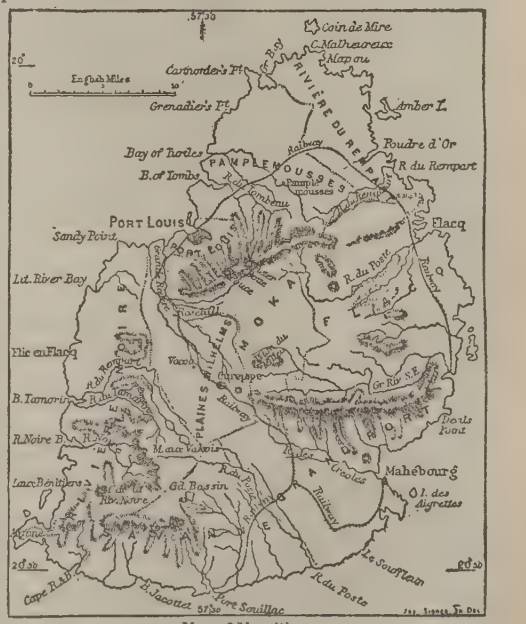
Both at King's College and at Cambridge Maurice gathered round him a band of earnest students, to whom he directly taught much that was valuable drawn from wide stores of his own reading, wide rather than deep, for he never was, strictly speaking, a learned man. Still more did he encourage the habit of inquiry and research, more valuable than his direct teaching. In his power, which has been truly called Socratic, of convincing his pupils of their ignorance he did more than perhaps any other man of our time to awaken in those who came under his sway the desire for knowledge and the process of independent thought.

If, as a social reformer, Maurice's name be forgotten in the future, it will be because in much he was before his time, and gave his eager support to schemes for which the world was not ready. From a very early period of his life in London the condition of the poor pressed upon him with consuming force; the enormous magnitude of the social questions involved was a burthen which he could hardly bear. He threw himself with characteristic energy into schemes for a true co-operative system, in which some ardent young men were then engaged, and in spite of his dislike for systems and party names did not shrink from being known as a Christian Socialist, and taking a keen interest in the paper which bore that name, and was the organ of the movement. That and the *Politics for the People*, much the same paper under a different name, received his sanction and aid; many strifes between masters and workmen were appeased, if not directly by himself, by those who were aided by his counsel, and were in constant intercourse with him. For many years he was the clergyman whom working men of all opinions seemed to trust even if their faith in other religious men and all religious systems had faded, and his power of attracting the zealot and the outcast resembled that of the Master whom he followed.

Maurice was twice married, first to a sister of John Sterling, secondly to a sister of his friend Archdeacon Hare. By his family ties and his closest friendships he came in contact with few but intellectual people. Thus while he wrote and spoke and worked for the average man he set that average somewhat high. Those who were privileged to know him did not know a more beautiful soul.

The following are Maurice's more important works. Some of them were rewritten and in a measure recast, and the date given is not necessarily that of the first appearance of the book, but of its more complete and abiding form. *Eustace Conway, or the Brother and Sister*, a novel, 1834; *The Kingdom of Christ*, 1842; *Christmas Day and other Sermons*, 1843; *The Unity of the New Testament*, 1844; *The Epistle to the Hebrews*, 1846; *The Religions of the World*, 1847; *Moral and Metaphysical Philosophy* (at first an article in the *Encyclopædia Metropolitana*), 1848; *The Church a Family*, 1850; *The Old Testament*, 1851; *Theological Essays*, 1853; *The Prophets and Kings of the Old Testament*, 1853; *Lectures on Ecclesiastical History*, 1854; *The Doctrine of Sacrifice*, 1854; *The Patriarchs and Lawgivers of the Old Testament*, 1855; *The Epistles of St John*, 1857; *The Commandments as Instruments of National Reformation*, 1866; *On the Gospel of St Luke*, 1868; *The Conscience: Lectures on Casuistry*, 1868; *The Lord's Prayer, a Manual*, 1870. The greater part of these works were, as has been already noticed, first delivered as sermons or lectures. Besides this more formal work, Maurice contributed many prefaces and introductions to the works of friends, as to Archdeacon Hare's *Charges*, Kingsley's *Saint's Tragedy*, &c. His occasional sermons, speeches, periodical writings, and letters to various newspapers need not be here noticed, though they were at the time evidence of his interest in all the life of his time, and his eager and abounding energy.

MAURITIUS, formerly called the ISLE OF FRANCE, an island in the south-western portion of the Indian Ocean, between 57° 18′ and 57° 48′ E. long., and 19° 58′ and 20° 31′ S. lat., 550 miles east of Madagascar, and 115 miles north-east of the island of Réunion, 940 miles south-east of the Seychelles, 2300 miles from the Cape of Good Hope, and 9500 miles from England *via* Aden and Suez. The island is irregularly elliptical—somewhat triangular—in shape, and is 36 miles long from north-north-east to south-south-west, and about 23 miles broad. It is 130 miles in circumference, and its total area is about 713 square miles. The island is surrounded by coral reefs, so that the ports are difficult of access.



Map of Mauritius.

From its mountainous character Mauritius is a most picturesque island, and its scenery is very varied and beautiful. The most level portions of the coast districts are the north and north-east, all the rest being broken by hills, which vary from 500 to 2700 feet in height. There are three principal masses of mountain: the north-western or Pouce range, in the district of Port Louis; the south-western, in the districts of Rivière Noire and Savanne; and the south-eastern range, in the Grand Port district. In the first of these, which consists of one principal ridge with several lateral spurs, overlooking Port Louis, are the singular peaks of the Pouce (2650 feet), so called from its supposed resemblance to the human thumb; and the still loftier Pieter Botte (2676 feet), a tall obelisk of bare rock, crowned with a globular mass of stone. The highest summit in the

island is in the south-western mass of hills, the Montagne de la Rivière Noire, which is 2711 feet above the sea. The principal ranges in this mountain mass are three in number, arranged in a triangular form, and are called respectively the mountains of La Pierre Rouge, La Rivière Noire, and Savanne. The south-eastern group of hills consists of one chief range, the Montagne du Bambou, with several spurs running down to the sea. In the interior are extensive fertile plains, some 1200 feet in height, and forming the districts of Moka, Vacois, and Plaines Wilhelms; and from nearly the centre of the island rises an abrupt peak, the Piton du Milieu de l'Île, to a height of 1932 feet above the sea-level. Other prominent summits are the Trois Mamelles, the Montagne du Corps de Garde, the Signal Mountain, near Port Louis, and the Morne Brabant, at the south-west corner of the island.

The rivers are of course small, and none of them are navigable beyond a few hundred yards from the sea. In the dry season most of them are little more than brooks, although they soon become raging torrents when swollen by the heavy rains of the wet period of the year. The principal stream is the Grande Rivière, with a course of about 10 miles. A remarkable and very deep lake, called Grand Bassin, is found in the south of the island, and is probably the extinct crater of an ancient volcano; other similar lakes are the Mare aux Vacois and the Mare aux Joncs, and there are some other deep hollows which have a like origin.

The geological structure of Mauritius is undoubtedly a result of volcanic action, all the rocks being of basalt and greyish-tinted lavas, excepting some beds of upraised coral. Columnar basalt is seen in several places. There are many caverns and steep ravines, and from the character of the rocks the ascents are rugged and precipitous. The island has few mineral productions, although iron, lead, and copper in very small quantities have in former times been obtained.

The climate is pleasant during the cool season of the year, but oppressively hot in summer (December to April), except in the interior plains, where the thermometer ranges from 70° to 80°, while in Port Louis and the coast generally it ranges from 90° to 96°. The mean temperature for the year at Port Louis is 78°·6. During the last thirty years the island has been subject to severe epidemics, which have been extremely fatal. In 1854 a visitation of Asiatic cholera swept off 17,000 people; and in 1867 a still more destructive inroad of malarial fever, of an unusually fatal type, almost paralysed the whole community for many weeks, carrying off 30,000 people, and greatly affecting the finances of the colony. The seasons are divisible into two, the cool and comparatively dry season, from April to November, and the hotter season during the rest of the year. From the month of January to the middle of April, Mauritius, in common with the neighbouring islands and the surrounding ocean from 8° to 30° of S. lat., is subject to severe and destructive cyclones, accompanied by torrents of rain, which often cause great destruction to houses and plantations. These hurricanes generally last about eight hours, but they appear to be now less frequent and violent than in former times, owing, it is thought, to the destruction of the ancient forests and the consequent drier condition of the atmosphere.

The soil of the island is of considerable fertility; it is a ferruginous red clay, but so largely mingled with stones of all sizes that no plough can be used, and the hoe has to be employed to prepare the ground for cultivation. The woods with which the island was largely clothed when first discovered have been to a great extent cut down, and the greater portion of the plains is now a vast sugar plantation. The bright green of the sugar fields is a striking feature in a view of Mauritius from the sea, and gives a peculiar beauty and freshness to the prospect. The soil is suitable for the cultivation of almost all kinds of tropical produce, and it is to be regretted that the prosperity of the colony depends entirely on one article of production, for the consequences are serious when there happens to be a failure, more or less, of the sugar crop. Guano is extensively imported as a manure, and by its use the natural fertility of the soil has been increased to a wonderful extent.

For purposes of law and government Mauritius is divided into nine districts, named respectively Port Louis, Pamplemousses, Rivière du Rempart, Flacq, Grand Port, Savanne, Moka, Plaines Wilhelms, and Rivière Noire. The capital and seat of government, the city of Port Louis, is situated on the north-western side of the island, at the head of an excellent harbour, a deep inlet about a mile long. This is protected by two forts,—Fort William and Fort George,—as well as by the citadel in the city, and its value is further increased by three graving docks connected with the inner harbour. Lighthouses have been erected on Flat Island and at Cannonier's Point. Port Louis has a population of about 70,000, but from the lofty mountains by which it is enclosed its situation is hot, and from the small amount of tide in the harbour effectual drainage is difficult, so that it is not a very healthy town. The public buildings are of no great architectural beauty, the government house being a three-storied structure with broad verandas, of no particular style of architecture, while the Protestant cathedral was formerly a powder magazine, to which a tower and spire has been added. The Roman Catholic cathedral is more pretentious in style, but is tawdry in its interior. In the city are large barracks and military stores. A maximum contribution of £45,000 is paid to the imperial government by the colony towards the expenses of the troops stationed in the island, but this sum is reduced when the garrison is below a certain standard. In 1880 the amount paid was £29,972. The governor and chief officers of government reside out of Port Louis in the cooler uplands of the interior, as do also a large number of the principal inhabitants, especially since the completion of the railways has made access easy to many portions of the island. The most favourite place of residence is at Curepipe, a place situated about 1800 feet above the sea; here the climate resembles that of the south of France, and it has been so much resorted to of late years that it is rapidly becoming a large town. The construction of the Mauritian railways has given a great impetus to the trade of the colony; the system embraces two lines, of a total length of 87 miles. The main roads of the island are kept in good order, but much yet remains to be done before the road system can be said to be complete throughout all the districts.

The prosperity of Mauritius, as already mentioned, depends almost entirely upon its sugar-crop, and the export trade of the island has greatly increased during the last twenty years, as will be seen by the following statistics:—

| | 1864. | 1868. | 1873. | 1877. | 1880. |
|---|---|---|---|---|---|
| Imports ... | £2,582,980 | £2,200,098 | £2,454,101 | £2,359,449 | £2,169,672 |
| Exports ... | 2,249,740 | 2,339,342 | 3,375,401 | 4,201,288 | 3,634,788 |

Of the imports the principal items are rice (about a fifth of the whole), wheat, and other grains, plain and coloured cottons, and haberdashery. Madagascar supplies cattle to the colony, and also rice, although the greater portion of the latter import comes from India. Horses are imported from the Cape, ponies from Burmah and Pegu, mules from Spain, and sheep from Bombay and the Cape. Of the exports, sugar forms of course the great item, amounting, on an average, to nearly nineteen-twentieths of the whole; the increase in its production is shown

by the following figures, giving values of the sugar exported :—

| 1864. | 1871. | 1877. | 1878. |
|---|---|---|---|
| £2,126,511 | £2,841,829 | £3,763,291 | £3,408,020 |

In 1877 the quantity of sugar exported was 189,164 tons; while in 1854 the quantity was 102,000 tons. The next item is rum, which was exported to the value of £45,386 in 1878; and the production of cocoa-nut oil has increased from 7569 gallons in 1864 to 253,263 gallons in 1878, the latter quantity being worth £37,263. The value of the coffee exported in 1879 was £25,064. The currency consists of rupees and cents; and on the 1st of May 1878, the metric system of weights and measures came into use in the island.

Mauritius being an oceanic island of small size, its present fauna is very limited in extent, and does not contain much that is interesting. When first seen by Europeans it contained no mammals except a large fruit-eating bat (*Pteropus vulgaris*), which is plentiful in the woods; but several animals of this class have been introduced, and are now numerous in the uncultivated region. Among these are two monkeys of the genera *Macacus* and *Cercopithecus*, a stag (*Cervus hippelaphus*), a small hare, a shrew-mouse, and the ubiquitous rat. A lemur and one of the curious hedgehog-like *Insectivora* of Madagascar (*Centetes ecaudatus*) have probably both been brought from the larger island. The avifauna resembles that of Madagascar; there are species of a peculiar genus of caterpillar shrikes (*Campephagidæ*), as well as of the genera *Pratincola*, *Hypsipetes*, *Phedina*, *Tchitrea*, *Zosterops*, *Foudia*, *Collocalia*, and *Coracopsis*, and peculiar forms of doves and parroquets. The living reptiles are small and few in number, but in the surrounding seas are great numbers of fish; the coral reefs abound with a great variety of molluscs; and there are numerous land-shells. The extinct fauna of Mauritius has considerable interest. In common with the other Mascarene islands, it was the home of the Dodo (*Didus ineptus*), one of a group of birds incapable of flight; there were also *Aphanapteryx*, a species of rail, and a short-winged heron (*Ardea megacephala*), which probably seldom flew. The defenceless condition of these birds has led to their extinction since the island was colonized. Several species of large fossil tortoises have been discovered; but, strange to say, they are quite different from the living ones of Aldabra, in the same zoological region.

Owing to the extensive destruction of the primeval forests of the island for the formation of sugar plantations, the indigenous flora of Mauritius is only seen in parts of the interior plains, in the river valleys, and on the hills; and it is so much mingled with trees and plants introduced from other parts of the world that it is not very easy to distinguish between what is native and what has come from abroad. The principal timber tree is the ebony (*Diospyros ebeneum*), which grows to a considerable size. Besides this there are bois de cannelle, olive-tree, benzoin (*Croton Benzoe*), colophane (*Colophonia*), and iron-wood, all of which are useful in carpentry; the cocoa-nut palm, an importation, but a tree which has been so extensively planted during the last hundred years that it is extremely plentiful; the palmiste (*Palma dactylifera latifolia*), the latanier (*Corypha umbraculifera*), and the date-palm. The vacoa or vacois, a species of *Pandanus*, is largely grown, the long tough leaves being manufactured into bags for the export of sugar, and the roots being also made of use; and in the few remnants of the original forests the tree which is such a prominent one in the coast flora of Madagascar, the traveller's tree (*Urania speciosa*), grows abundantly. A species of bamboo is very plentiful in the river valleys and in marshy situations. A large variety of fruit is produced, including the tamarind, mango, banana, pine-apple, guava, shaddock, fig, avocado-pear, litchi, custard-apple, and the mabolo (*Diospyros discolor*), a fruit of exquisite flavour, but very disagreeable odour. Many of the roots and vegetables of Europe have been introduced, as well as some of those peculiar to the tropics, including maize, millet, yams, manioc, dhol, gram, &c. Small quantities of tea, rice, and sago have been grown, as well as many of the spices (cloves, nutmeg, ginger, pepper, and allspice), and also cotton, indigo, betel, camphor, turmeric, and vanilla.

Mauritius appears to have been unknown to European nations, if not to all other peoples, until the year 1507, when it was discovered by the Portuguese. It had then no inhabitants, and there seem to be no traces of its previous occupation by any people, either savage or civilized. The island was retained for most of the 16th century by its discoverers, but they made no colonies in it. In 1598 the Dutch took possession, and named the island "Mauritius," in honour of their prince Maurice. It had been previously called by the Portuguese "Ilha do Cerné," from the belief that it was the island so named by Pliny. But, although the Dutch built a fort at Grand Port, they made no permanent settlement in Mauritius, finally abandoning the island in 1710. Five years afterwards the French, in their turn, took possession of what had seemed so worthless to two European powers, but it was half a century before the Government of France appreciated the value of their colony, since from 1715 to 1767 it was held by agents of the French East India Company, by whom its name was again changed to "Ile de France." The Company was fortunate in having several able men as governors of its colony, especially the celebrated Mahé de Labourdonnais (1735–46), "a man of eminent talents and virtue," who introduced the culture of the sugar-cane, and thus laid a firm foundation for the future prosperity of the island. Under his direction roads were made, forts built, and considerable portions of the forest were cleared, and the present capital, Port Louis, was founded. Labourdonnais also promoted the planting of cotton and indigo, and is justly remembered as the most enlightened and best of all the French governors. The colony continued to rise in value during the time it was held by the French crown, and to one of the later governors, De Poivre, was due the introduction of the clove, nutmeg, and other spices. Another governor was D'Entrecasteaux, whose name is kept in remembrance by a group of islands east of New Guinea.

During the long war between France and England, at the commencement of this century, Mauritius was a continual source of much mischief to English Indiamen and other merchant vessels; and at length the British Government determined upon an expedition for its capture. This was effected in 1810; and upon the restoration of peace in 1814 the possession of the island was confirmed to England by one of the provisions of the treaty of Paris. By the eighth article of capitulation it was agreed that the inhabitants should retain their own laws, customs, and religion; and so it happens that, although a British colony, the island is still largely French in language, habits, and predilections; but its name has again been changed to that given by the Dutch. Perhaps the most distinguished of the English governors of the island was Sir Robert Farquhar (1810–23), who did so much to abolish the Malagasy slave trade and to establish friendly relations with the rising power of the Hova sovereign of Madagascar.

Mauritius is one of the crown colonies of Great Britain, and at the head of its administration is a governor, who is assisted by an executive council of seven members, holding the most important Government posts. There is also a legislative council, which consists of the same members as the foregoing, with three others, together with eight of the chief landed proprietors of the island, who are nominated by the crown. The average annual revenue of the colony for the ten years from 1871 to 1880 was £723,876, the average annual expenditure during the same period being £710,261. Up to 1854 there was a surplus in hand, but since that time expenditure has exceeded income, and the public debt is now about £700,000.

The island has largely retained the old French laws, the Codes Civile, de Procédure, du Commerce, and d'Instruction Criminelle being still in force, except so far as altered by the later laws for the administration of justice of April 13, 1831. By these the court of appeal was reconstituted, and a supreme court of civil and criminal justice was established, under a chief judge and three puisne judges. The police force in 1880 included 689 men.

During the last few years great improvements have been effected in the educational system of the colony. The department of public instruction has two branches, the Royal College, for higher education, and the school department, for primary instruction. In 1880 the number of Government schools was 38, with 5077 scholars, and of schools aided by grants 54, with 4316 scholars, the total teaching staff numbering 178. The annual education vote is about £18,000; and of the scholars 73 per cent. are Roman Catholic, 14 per cent. Hindu, 8 per cent. Protestant, and 5 per cent. Mohammedan. It will be seen from the above figures that the Roman Catholic religion is that professed by the large majority of the white population of Mauritius. The clergy supported by the state include the Protestant bishop of Mauritius, with an archdeacon and seven clergymen of the Church of England, and three clergymen of the Church of Scotland; and the Roman Catholic bishop of Port Louis, with a vicar-general and thirty-four priests.

The population of the island is a very varied one, and consists of two great divisions:—those of European blood, chiefly French and English, as well as numerous half-caste people; and a large coloured population, chiefly Hindu coolies, but with representatives from various African and Asiatic regions, Negroes, Malagasy, Parsees, Singhalese, Chinamen, Malays, &c. The Hindu immigrants now form more than two-thirds of the inhabitants of Mauritius, as will be seen from the following figures for the year 1881 :—

| General.....111,783 | | Indian.....249,064 | | Total.....360,847 | |
|---|---|---|---|---|---|
| Male. | Female. | Male. | Female. | Male. | Female. |
| 58,137 | 53,646 | 151,423 | 97,641 | 209,560 | 151,287 |

The increase of population during the last thirty years is shown by the following figures :—

| 1851. | 1861. | 1871. | 1881. |
|---|---|---|---|
| 183,506 | 313,469 | 317,069 | 360,847 |

The system of coolie immigration has been of great value to the colony; and the arrangements for shipping these Hindu people

are under Government control. But many of the laws have been so unjust to the coloured people, and so much to the advantage of the planters, that gross evils and abuses have arisen. And, unjust as the laws are, their administration has often been still more unfair. The evil grew at length so glaring that in 1871 a royal commission was appointed, which sat for a long time investigating the subject. Various reforms were recommended, and since then some improvements have been effected. But many of the creole planters are not remarkable for their respect for the rights of coloured people, and the system is liable to gross abuse unless under vigilant control by higher authority. Much yet remains to be done for the moral and religious instruction of the labourers; and the presence of a large heathen population, and the prevalence of crime, has been at times a very serious consideration for the colony. The number of coolies arriving in and leaving the island varies very largely, from a few hundreds annually to several thousands.

The dependencies of Mauritius are the Seychelles group, the islands of Rodriguez and Diego Garcia, the Chagos group, and seventy other smaller islands scattered over a large extent of the Indian Ocean, and having a total population of about 16,000 souls. Rodriguez is situated 300 miles east of Mauritius, and is cultivated chiefly by colonists from that island.

*Literature.*—The following works supply fuller details than can be given in this article:—Ch. Grant, *History of Mauritius, or the Isle of France and Neighbouring Islands*, 1801; J. Milbert, *Voyage pittoresque à l'Île-de-France*, &c., 4 vols., 1812; Aug. Billiard, *Voyage aux Colonies orientales*, 1822; D'Unienville, *Statistique de l'île Maurice*, &c., 1838; J. Backhouse, *Narrative of a Visit to the Mauritius and South Africa*, 1844; P. Beaton, *Creoles and Coolies, or Five Years in Mauritius*, 1859; Paul Chasteau, *Histoire et Description de l'île Maurice*, 1860; F. P. Flemyng, *Mauritius, or the Isle of France*, 1862; James Morris, "Mauritius, its Commercial and Social Bearings," *Soc. Arts Jour.*, 1862; A. Erny, "Séjour à l'île Maurice," in vol. vii. of *Tour du Monde*, 1863; Ch. J. Boyle, *Far Away, or Sketches of Scenery and Society in Mauritius*, 1867; L. Simonin, *Les Pays lointains, Notes de Voyage (Maurice, &c.)*, 1867; N. Pike, *Sub-Tropical Rambles in the Land of the Aphanapteryx*, 1873; A. R. Wallace, "The Mascarene Islands," in chap. xi. vol. i. of *The Geographical Distribution of Animals*, 1876; K. Möbius, F. Richter, and E. von Martens, *Beiträge zur Meeresfauna der Insel Mauritius und der Seychellen*, Berlin, 1880; G. Clark, *A Brief Notice of the Fauna of Mauritius*, 1881. (J. S., jr.)

MAURUS, St, according to the Roman Breviary (January 15), was a Roman of noble birth, and while still a child was placed by his father Eutychius under the discipline of St Benedict, where he soon became a model of all the virtues and endowed with the gift of miracles. Sent by his master into Gaul, he founded a monastery over which he presided for forty years. When he died in 565 he was over seventy. The monastery referred to is that of Glanfeuil or St Maur-sur-Loire. In point of fact it may be said that everything relating to the introduction of the Benedictine order into France, unless the name of him who introduced it be made an exception, is purely legendary. The famous "Congregation of St Maur" dates from the 17th century, having received papal sanction in 1621 and 1627; it arose out of an earlier "congregation" of reformed Benedictines, which took its name from St Vannes near Verdun, and was sanctioned by Clement VIII.

MAURY, Jean Siffrein (1746–1817), cardinal and archbishop of Paris, the great opponent of Mirabeau in the constituent assembly, and esteemed his rival in eloquence, was the son of a poor cobbler, and was born at Valréas in the Venaissin, the district in France which belonged to the pope. His quickness was soon observed by the priests of Avignon, where he was educated and took orders, and he determined to get what he could by it. He tried his fortune by writing *éloges* of famous persons, then a favourite practice; and in 1771 his *éloge* on Fénelon was pronounced next best to Laharpe's by the Academy. The real foundation of his fortunes was the success of a sermon he preached on St Louis before the Academy in 1772, which caused him to be recommended to the king for an abbacy on the spot. In 1772 he published his *Essai sur l'éloquence de la chaire*, which, as well as his *Principes d'éloquence*, contains much good criticism, and remains a French classic. He became a favourite preacher in Paris, and was Lent preacher at court in 1781, when King Louis XVI. said of his sermon, "If the abbé had only said a few words on religion he would have discussed every possible subject." In 1781 he obtained the rich abbey of Lions, worth 20,000 livres a year, and in 1785 he was elected to the Academy. His morals were as loose as those of his great rival Mirabeau, but he was famed in Paris for his wit and gaiety as well as for his eloquence and his immorality. In 1789 he was elected a member of the states-general by the clergy of Péronne, and from the first proved to be the most able and persevering defender of the *ancien régime*. It is said that he attempted to emigrate both in July and in October 1789; but, whether he did or not, he after that time held firmly to his place, when almost universally deserted by his friends. His life was often in danger among the people, but his ready wit always saved it, and it was said that one *bon mot* would preserve him for a month. At last, in 1792, he found it necessary to fly from Paris; the Revolution had gone too far. When he did emigrate he found himself regarded as a kind of martyr to the church and the king, and was at once named cardinal, archbishop *in partibus*, and extra nuncio to the diet at Frankfort. He was finally made bishop of Montefiascone, and settled down in that little Italian town,—but not for long, for in 1796 the French drove him from his retreat, and he became ambassador, but with hardly any pay, of the exiled king Louis XVIII. to the pope. Such a life soon wearied a man who had been accustomed to wealth and reputation, and in 1804 he began to prepare his return to France by a well-turned letter to Napoleon, congratulating him on restoring religion to France once more. In 1806 he did return; in 1807 he was again received into the Academy; and in 1810, on the refusal of Cardinal Fesch, was made archbishop of Paris. On the restoration of the Bourbons he was summarily turned out of the Academy, and sent to Rome to answer for his disobedience to the pope. There he was imprisoned in the castle of St Angelo for six months, and died in 1817, a year or two after his release, of disease contracted in prison, and of chagrin.

There are two sides to Maury's character to be discussed. As a critic he was a very able writer, and Sainte-Beuve gives him the credit of discovering Bridaine, and giving Bossuet his rightful place as a preacher above Massillon; as a politician, his wit and eloquence make him a worthy rival of Mirabeau, and an interesting character in the early years of the Revolution. If in later years he forsook his old tenets, and joined Napoleon, his punishment was terribly severe, and it would have been a graceful act if Louis XVIII. had remembered the courageous supporter of Louis XVI., and the pope the one intrepid defender of the church in the states-general.

The *Œuvres choisis d'u Cardinal Maury* (5 vols., 1842) contain what is worth preserving. For his life and character see *Vie du Cardinal Maury par son neveu*, 1827; Poujoulat, *Cardinal Maury, sa vie et ses œuvres*, 1855; Sainte-Beuve, *Causeries du Lundi*, vol. iv.

MAURY, Matthew Fontaine (1806–1873), American naval officer and hydrographer, was born in Spottsylvania county, Virginia, January 14, 1806. In 1825 he entered the American navy as midshipman, circumnavigating the globe in the "Vincennes," during a cruise of four years. In 1836 he was made lieutenant, and gazetted astronomer to an exploring expedition. In 1839 he met with an accident which resulted in permanent lameness, and unfitted him for active service. Maury was placed in charge of the Depôt of Charts and Instruments, out of which have grown the United States Naval Observatory and the Hydrographic Office. He laboured assiduously and with complete success to place the depôt in a state of efficiency. While in the "Vincennes," and in subsequent cruises, Maury made many observations as to the winds and currents, and when in charge of the Hydrographic Office he set himself to collect further data by distributing to captains of vessels specially prepared log-books. So successful was he in this enterprise that in the course of nine years he had collected a sufficient number of logs to make two hundred manuscript volumes, each with about two thousand five hundred days' observations. One result was to show the necessity for combined action on the part of maritime nations in regard to ocean meteorology. This led to an

international conference at Brussels in 1853, which produced the greatest benefit to navigation as well as indirectly to meteorology. One result was the establishment of the meteorological department of the English Board of Trade, now known as the Meteorological Office, which adopted Maury's model log-books. In 1853 he published his *Letters on the Amazon and Atlantic Slopes of South America*, and in 1855 he was promoted to the rank of commander. On the outbreak of the American civil war in 1861, Maury threw in his lot with the South, and, having lost nearly his all, retired to England, where he was presented with a handsome testimonial raised by public subscription. Afterwards he became imperial commissioner of emigration to Maximilian of Mexico, on whose death he took up his residence in Virginia, where he died on February 1, 1873.

In 1848 Maury published a *Treatise on Navigation*, which was long used as a text-book in the United States navy. The work, however, by which he is best known is his *Physical Geography of the Sea*, the first edition of which was published in London in 1855, and in New York in 1856; it was translated into several European languages. The theories which it contains are now generally admitted to be quite erroneous. Maury's reputation rests on the eminent services he rendered to navigation and meteorology, he having been the first to show how the latter could be raised to the certainty of a science. He was essentially a practical man; his great aim was to render navigation more secure and economical, and in this he was eminently successful. Other works published by Maury are the papers contributed by him to the *Astronomical Observations* of the United States Observatory, *Letters concerning Lines for Steamers crossing the Atlantic* (1854), *Physical Geography* (1864), and *Manual of Geography* (1871). In 1859 he began the publication of a series of nautical monographs.

MAUSOLUS, or according to his coins *Maussolus* (Μαύσσωλος), a king of Caria, whose reign probably began in 377 and terminated with his death in 353 B.C. The part he took in the revolt against Artaxerxes Memnon, his conquest of Lydia, Ionia, and several of the Greek islands along the coast, his co-operation with the Rhodians and their allies in the war against Athens, and the removal of his capital from Mylasa, the ancient seat of the Carian kings, to the city of Halicarnassus are the leading facts of his history. He is best known, however, from the tomb erected for him by his widow Artemisia with such cultured magnificence that the name of mausoleum has become the generic title of all similar monuments. One of the most curious of the inscriptions discovered at Mylasa details the punishment of certain conspirators who had attempted the life of Mausolus when he was attending a festival in a temple at Labranda. See HALICARNASSUS.

MAXENTIUS, MARCUS AURELIUS VALERIUS, Roman emperor from 306 to 312, was the son of Maximianus Herculius, and the son-in-law of Galerius, but on account of his vices and incapacity was left out of account in the division of the empire which took place in 305. A variety of causes, however, had produced strong dissatisfaction at Rome with many of the arrangements established by Diocletian, and the public discontent on October 28, 306, found expression in the massacre of those magistrates who maintained their loyalty to Severus and in the election of Maxentius to the imperial dignity,—an election in which the rest of Italy, as well as Africa, concurred. With the help of his father, Maxentius was enabled to put Severus to death and to repel the invasion of Galerius; his next steps were first to banish Maximian, and then, after achieving a military success in Africa against one Alexander, to declare war against Constantine for the conduct towards the old emperor of which he in turn had been guilty at Marseilles. The contest resulted in the defeat of Maxentius at Saxa Rubra, and his death by drowning in the Tiber at the Milvian Bridge on October 28, 312. (See CONSTANTINE.) The general testimony to the worthlessness and brutality of his character is unambiguous and unanimous; less apparent are the grounds for the particular statement of Gibbon that he was "just, humane, and even partial towards the afflicted Christians."

MAXIMA AND MINIMA. The consideration of the greatest or the least value of a variable quantity, that is restricted by certain conditions, is a problem of which several simple cases were investigated by the early Greek geometers. Thus in Euclid iii. 7, 8 we find the determination of the greatest and least right lines that can be drawn from a point to the circumference of a circle. But the most characteristic problem of the kind in Euclid is that contained in vi. 27, 28, 29. Thus prop. 27, when reduced to its simplest form, is equivalent to the statement that if a right line be bisected the rectangle under the segments is greater than that under those made by any other point of division. Props. 29 and 30 are, when considered algebraically, reducible to the solution of the equations $x(a-x)=b^2$ and $x(a+x)=b^2$, coupled with the determination of the maximum value of $b$ for which the solution of the former is possible (see Matthiessen, *Grundzüge der antiken und modernen Algebra*, Leipsic, 1878). Apollonius extended the investigation of Euclid, bk. iii., to the problem of the greatest and least distances of a point from an ellipse, showing that it depended on drawing normals from the point to the curve; and he reduced the latter problem to finding the points of intersection of the ellipse with a certain hyperbola.

The next remarkable problems on maxima and minima are said to have been investigated by Zenodorus,[1] and were preserved by Pappus and Theon of Alexandria. Of these we may mention the following:—(1) among regular polygons of equal perimeter that of the greatest number of sides contains the greatest area; (2) of polygons of the same perimeter and the same number of sides the regular polygon contains the greatest area; (3) the circle contains a greater area than any other curve or polygon of the same perimeter; (4) the sphere contains the greatest volume for a given superficial area.

In the progress of mathematics the terms maxima and minima have come to be used to imply, not the absolutely greatest and least values of a variable magnitude, but the value which it has at the moment it ceases to increase and begins to decrease, or *vice versa*. For example, if it be said that the height of the barometer is a maximum at any instant it means that up to that time the barometer was rising and then began to fall. In this way it is possible that there should be several maxima and minima in the course of one day, and that one of the minima should be greater than one of the maxima.

The theory of maxima and minima, in the differential calculus point of view, is very simple. Thus, if $u$ be a given function of a variable $x$, the values of $x$ for which $u$ has a maximum or a minimum value are, in general, determined by the equation $\frac{du}{dx}=0$. Again, if $u$ be a function of two variables $x$ and $y$, then the maximum or minimum values of $u$ must satisfy the equations $\frac{du}{dx}=0$ and $\frac{du}{dy}=0$. There is, however, no real maximum or minimum solution if $\left(\frac{d^2u}{dxdy}\right)^2$ is greater than $\frac{d^2u}{dx^2}\frac{d^2u}{dy^2}$. A short account of this method, illustrated by examples, is given in vol. xiii. pp. 23, 24.

John Bernoulli's problem (*Acta Eruditorum*, June 1696) of the "brachystochrone," *i.e.*, of the curve of quickest descent under the action of gravity, differed essentially

[1] Montucla (*Hist. de Math.*, tom. i. p. 113) erroneously attributed these theorems on isoperimetry to Pythagoras, but his statement is based on a misinterpretation of a passage in Diogenes Laertius. See Bretschneider, *Die Geometrie vor Euklides*, pp. 89, 90.

from all problems on maxima and minima which had been previously solved. In this he introduced into mathematics the conception of a new and most important class of problems. James Bernoulli, also, in his solution of this problem of his brother, proposed a more general question, which may be stated as follows:—"Of all curves of the same length described on a given base to determine one such that the area of a second curve, each of whose ordinates is a given function of the corresponding ordinate, or arc, of the first, may be a maximum, or a minimum." Such problems were styled "isoperimetrical," and come under a class now called *relative* maxima and minima, in which the maximum or minimum curve is to be determined, not from all possible curves, but from among those which possess a given property. The investigations of the Bernoullis were extended and generalized by other eminent mathematicians, but more especially by Euler, and culminated in the invention of the calculus of variations, with an appropriate notation, by Lagrange.

MAXIMIANUS, Marcus Aurelius Valerius, surnamed Herculius, Roman emperor from 286 to 305, and again in a doubtful manner for some time prior to 308, was by birth a Pannonian peasant, but achieved great distinction in the course of long service in the army in almost every quarter of the empire, and, having been made Cæsar by Diocletian in 285, received the title of Augustus in the following year (April 1, 286) with the honorary appellation of Herculius. In 287 he suppressed the rising of the peasants (Bagaudæ) in Gaul, but in 289, after a three years' struggle, his colleague and he were compelled to acquiesce in the assumption by his lieutenant Carausius of the title of Augustus in Britain. After 292, Maximian left the care of the Rhine frontier to Constantius Chlorus, who had been designated Cæsar in that year, but in 297 his arms achieved a rapid and decisive victory over the barbarians of Mauretania, and in November 303 he shared at Rome the triumph of Diocletian, the last pageant of the kind ever witnessed by that city. On May 1, 305, the day of Diocletian's abdication, he also, but without his colleague's sincerity, divested himself of the imperial dignity at Milan, which had been his capital, and retired to a villa in Lucania; in the following year, however, he was induced by his son Maxentius to reassume the purple. In 307 he brought the emperor Severus a captive to Rome, and also compelled the retreat of Galerius, but in 308 he was himself driven by Maxentius from Italy into Illyricum, whence again he was compelled to seek refuge at Arles, the court of his son-in-law Constantine. Here a false report was received, or invented, of the death of Constantine, at that time absent on the Rhine, and Maximian at once grasped at the succession, but was soon driven to Marseilles, where, having been delivered up to his pursuers, he strangled himself in 310 (February).

MAXIMIANUS, Galerius Valerius, usually referred to by his name Galerius, Roman emperor from 305 to 311, was born near Sardica in Dacia, and originally followed his father's occupation, that of a herdsman, whence his surname of Armentarius. He served with distinction as a soldier under Aurelian and Probus, and in 292 was designated Cæsar along with Constantius, receiving in marriage Diocletian's daughter Valeria, and at the same time having assigned to him as his special charge the care of the Illyrian provinces. In 296, at the beginning of the Persian war, he was removed from the Danube to the Euphrates; his first campaign ended in a crushing defeat on the same field as that which had proved fatal to Crassus, but in 297, advancing through the mountains of Armenia, and taking the enemy by surprise, he gained a victory over Narses by which his military reputation was more than restored. In 305, on the abdication of Diocletian and Maximian, he at once assumed the title of Augustus, along with Constantius his former colleague, and, having procured the promotion to the rank of Cæsar of Severus, a faithful servant, and Daza (Maximinus), his nephew, he hoped on the death of Constantius to become sole master of the Roman world. This scheme, however, was defeated by the sudden elevation of Constantine at York on the death of his father, and by the action of Maximian and Maxentius in Italy. After an unsuccessful invasion of Italy in 307 he elevated his friend Licinius to the rank of Augustus, and, moderating his ambition, devoted the few remaining years of his life "to the enjoyment of pleasure and to the execution of some works of public utility." He died—of the *morbus pedicularis*, it is said—in May 311. It was at the instance of Galerius that the first of the celebrated edicts of persecution against the Christians was published, on February 24, 303, and this policy of repression was maintained by him until the appearance of the general edict of toleration, running in his own name and in those of Licinius and Constantine.

MAXIMILIAN I. (1459–1519), holy Roman emperor, the son of the emperor Frederick III., was born on the 22d of March 1459. In 1477 he married Mary, daughter of Charles the Bold of Burgundy, thus securing for his family the possessions of the house of Burgundy; and by the marriage of his son Philip with the infanta Joanna in 1496 he prepared the way for the association of Spain with the empire under his grandson, Charles V. In 1486 Maximilian was chosen king of the Romans, and in 1493, after the death of his father, he succeeded to the imperial throne. During the reign of Frederick III. the system of private war created profound discontent, and there were urgent demands for the reform of imperial institutions. Maximilian was never thoroughly in sympathy with this movement, but at his first diet, in 1495, he declared a perpetual public peace; and he did something for the restoration of order by the establishment, in the same year, of the imperial chamber (*Reichskammergericht*), and, in 1501, of the imperial Aulic council (*Reichshofrath*). Another important change was the division of Germany into six, afterwards (in 1512) into ten, circles (*Kreise*), over each of which was placed a captain with a force for the punishment of disturbers of the peace. Standing troops, called Landsknechte, were for the first time organized by Maximilian, who also improved the artillery then in use, and issued good police regulations. He encouraged science, art, and literature, devoted much attention to the universities, especially those of Vienna and Ingolstadt, collected mediæval poems, and caused copies to be made of ancient chronicles and other important manuscripts. Through the influence of his second wife, Blanca Sforza, daughter of Duke Galeazzo Sforza of Milan, he was induced to contend for supremacy in Milan and Naples; but his resources were inadequate for war on equal terms with the kings of France, Charles VIII. and Louis XII. In 1499 he carried on an unsuccessful war with the Swiss confederates, the result of which was that, by the peace of Basel, the confederates became practically independent of the empire. On the other hand, he was singularly fortunate in increasing the power of the house of Austria. By the death of his cousin, the archduke Sigismund, he inherited Tyrol; he also received Görz, Gradisca, the Pusterthal, and a part of Bavaria; and by the marriage of two of his grandchildren with children of the king of Hungary and Bohemia he took the first step towards the ultimate incorporation of these countries with the Austrian hereditary territories. He wrote several books, and planned the "Weiss-Kunig," a kind of poetical autobiography, completed by his private secretary, Treizsaurwein von Erentreiz. Maximilian had some part also in the preparation of *Theuerdank*, an

allegory setting forth adventures in connexion with his marriage with Mary of Burgundy. At Wels, in Upper Austria, on the 12th of January 1519, he died.

See Klüpfel, *Kaiser Maximilian* I., 1864.

MAXIMILIAN II. (1527–1576), holy Roman emperor, son and successor of Ferdinand I., was born at Vienna on the 1st of August 1527. He was of a mild and tolerant disposition, and in youth received a favourable impression of Protestantism from his tutor, Wolfgang Severus,—an impression which was not effaced by a residence of three years at the Spanish court. In 1562 he became king of Bohemia and king of the Romans, in 1563 king of Hungary, and in 1564 emperor. At the time of his accession to the imperial throne Hungary was at war with Turkey. The sultan Soliman II. was conciliated by the cession of all the territories he had conquered in Hungary, and by the promise of a yearly tribute of 300,000 florins. Soon afterwards Soliman renewed the war on behalf of the prince of Transylvania; but after his death in 1566 his successor, Selim, concluded with Maximilian an armistice of eight years. Maximilian's brothers, Ferdinand and Charles, fought incessantly against Protestantism in their respective lands; but it was tolerated by Maximilian in Austria, Bohemia, and Hungary. His authority, however, was greatly limited by the influence of the Jesuits. He died on the 12th of October 1576. Of his eight children (six sons and two daughters) two—Rudolph II. and Matthias—became emperors.

See Koch, *Quellen zur Geschichte des Kaisers Maximilian II.*, 1857–61; and Wertheimer, *Zur Geschichte des Türkenkriegs Maximilians II.*, 1875.

MAXIMILIAN (1832–1867), archduke of Austria (Ferdinand Maximilian Joseph) and emperor of Mexico, was the second son of the archduke Francis Charles, and was born in Vienna on July 6, 1832. He was trained for the navy, and ultimately attained a high command in that branch of his country's service. In February 1857 he was appointed governor of the Lombardo-Venetian kingdom, and in the same year he married the Princess Charlotte, daughter of Leopold I., king of the Belgians. On the outbreak of the war of 1859, he retired into private life, chiefly at Trieste, until 1863, when at the instance of Napoleon III. he accepted the crown which had been offered to him by the notables of Mexico. He landed at Vera Cruz on May 28, 1864, but from the commencement of his reign found himself involved in difficulties of the most serious kind, which in 1866 made apparent to almost every one outside of Mexico the necessity for his abdicating. This, however, he declined to do. Withdrawing, in February 1867, to Querétaro, he there sustained a siege for several weeks, but on May 15 resolved to attempt an escape through the enemy's lines. He was, however, arrested before he could carry out this resolution, and, after trial by court martial, was condemned to death. The sentence was carried out on June 19, 1867. His remains were conveyed to Vienna, where they were buried in the imperial vault early in the following year. See Mexico. Maximilian's papers were published in 1867 in seven volumes, under the title *Aus meinem Leben, Reiseskizzen, Aphorismen*, &c.

MAXIMINUS, Caius Julius Verus, Roman emperor from 235 to 238, was of barbarian parentage, his father being a Goth and his mother an Alan, and was born in a village on the confines of Thrace, where his immense stature and enormous feats of strength first drew the attention of the emperor Septimius Severus. From being a shepherd he became a soldier, and under Caracalla rose to the rank of centurion. He carefully absented himself from court during the reign of Elagabalus, but rose to the first military command under his successor Alexander Severus. On March 19, 235, the troops saluted him emperor, and shortly afterwards Alexander was put to death. The three years of his reign, which were spent wholly in the camp, were marked by great cruelty and oppression; the widespread discontent thus produced culminated in a revolt in Africa and the assumption of the purple by Gordianus (*q.v.*). Maximin, who was in Pannonia at the time, marched against Rome, and passing over the Julian Alps descended on Aquileia; while detained before that city he and his son were murdered in their tent by a body of prætorians. Their heads were cut off and despatched to Rome, where they were burnt on the Campus Martius by the exultant crowd (May 238).

MAXIMINUS, Galerius Valerius, Roman emperor from 308 to 314, was originally an Illyrian shepherd, and bore the name of Daza. His mother was a sister of him who afterwards became the emperor Galerius. He rose to high distinction after he had joined the army, and in 305 he was raised by his uncle to the rank of Cæsar, with the honorary appellation of Jovius, Syria and Egypt being the government assigned to him. In 308, after the elevation of Licinius, he insisted on receiving the title of Augustus; on the death of Galerius in 311 he succeeded to the supreme command of the provinces of Asia, and, when Licinius and Constantine began to make common cause with one another, Maximin entered into a secret alliance with Maxentius. He came to an open rupture with Licinius in 313, sustained a crushing defeat in the neighbourhood of Heraclea on April 30th, and, having fled with extraordinary celerity first to Nicomedia and afterwards to Tarsus, perished at the latter city in August following. His death was variously ascribed "to despair, to poison, and to the Divine justice." Maximin, in every respect a worthless character, has a bad eminence in the annals of the Christian church as having renewed persecution after the publication of the toleration edict of Galerius.

MAXIMUS, the name of four Roman emperors. In chronological order the first was M. Clodius Pupienus Maximus, who was associated with Balbinus in the imperial dignity by the senate for a short time in 238, before and after the death of the hated Maximin. The second was Magnus Clemens Maximus, a native of Spain, who shared the imperial dignity with Valentinian and Theodosius from 383 to 388. He had accompanied Theodosius on several expeditions, and from 368 held high military rank in Britain. The disaffection of the Roman troops towards the emperor Gratian found expression in 383 in the proclamation of Maximus as emperor,—whether with or without his complicity in the act is uncertain. Voluntarily or under compulsion Maximus forthwith attacked Gratian in Gaul, and drove him from Paris to Lyons, where the fugitive was murdered. Circumstances made it difficult for Theodosius at the time to avenge the death of his colleague by war, and an agreement was therefore come to by which Maximus was recognized as Augustus and sole emperor in Gaul, Spain, and Britain, while Valentinian was to remain unmolested in Italy and Illyricum, Theodosius retaining his sovereignty in the East. A prosperous reign of four years having tempted Maximus, in 387, to pass the Alps, Valentinian was speedily put to flight, while the invader established himself in Milan, and for the time became master of Italy. Theodosius now took vigorous measures: advancing a powerful army by land, he utterly defeated the western troops at Siscia (Sciszek) in Pannonia, and, passing the Julian Alps with great rapidity, came upon Maximus, who had fled to Aquileia, seized him, and caused him to be beheaded (August 388). The third, Maximus Tyrannus, was made emperor in Spain by the Roman general Gerontius,

who had rebelled against Constantine in 408. After the defeat of Gerontius at Arles, and his subsequent death in 411, Maximus renounced the imperial title and was permitted by Constantine to retire into private life. About 418 he rebelled again, but, failing in his attempt, was seized, carried into Italy, and put to death at Ravenna in 422. Lastly, Petronius Maximus was a member of the higher Roman nobility, and had held a large number of public offices, including those of præfectus Romæ (420) and of præfectus Italiæ (439–441 and 445). He was one of the intimate associates of Valentinian, who received his assistance in the palace intrigues which led to the death of Aetius in 454; but a brutal outrage committed on the wife of Maximus by the emperor turned his friendship into the bitterest hatred. Maximus was proclaimed emperor immediately after Valentinian's murder in March 455, but reigned for less than three months, having been murdered by some Burgundian mercenaries as he was flying before the Vandals, who, invited by Eudoxia, the widow of Valentinian, had landed at the mouth of the Tiber (May or June 455).

MAXIMUS, St, abbot of Chrysopolis, known as "the Confessor" from his orthodox zeal in the Monothelite controversy, or as "the monk," was born of noble parentage at Constantinople about the year 580. Educated with great care, he early became distinguished by his talents and acquirements, and some time after the accession of the emperor Heraclius in 610 was made his private secretary. In 630 he abandoned the secular life and entered the monastery of Chrysopolis (Scutari), actuated, it was believed, less by any longing for the life of a recluse than by the dissatisfaction he felt with the Monothelite leanings of his master. The date of his promotion to the abbacy is uncertain. In 633 he was one of the party of Sophronius at the council of Alexandria; and in 645 he was again in Africa, when he held in presence of the governor and a number of bishops the disputation with Pyrrhus, the deposed and banished patriarch of Constantinople, which resulted in the (temporary) conversion of his interlocutor to the Dyothelite view. In the following year several African synods, held under the influence of Maximus, declared for orthodoxy. In 649, after the accession of Martin I., he went to Rome, and did much to fan the zeal of the new pope, who in October of that year held the (first) Lateran synod, by which not only the Monothelite doctrine but also the moderating *ecthesis* of Heraclius and *typus* of Constans II. were anathematized. About 653 Maximus, for the part he had taken against the latter document especially, was apprehended by order of Constans and carried a prisoner to Constantinople, and in 655, after repeated examinations, in which he maintained his theological opinions with memorable constancy, was banished to Byzia in Thrace, and afterwards to Perberis. In 662 he was again brought to Constantinople and was condemned by a synod there to be scourged, to have his tongue cut out by the root, and to have his right hand chopped off. After this sentence had been carried out he was again banished to Lazica, where he died on August 13, 662. He is venerated as a saint both in the Greek and in the Latin Church,—in the former on January and on August 12th and 13th, in the latter on August 13th.

A collection of his works, which are of importance for the history of the Monothelite controversy, was undertaken by Combefis, who published two volumes in 1675 (*S. Maximi Confessoris, Græcorum Theologi, eximiique Philosophi Opera*), but did not live to complete his labours. A list of the more important of the writings of Maximus, with bibliographical details, will be found in Smith's *Dictionary of Biography and Mythology*; an exhaustive "Catalogue raisonné," by Wagenmann, occurs in vol. ix. (1881) of the new edition of Herzog's *Real-Encyklopädie*. The details of the disputation with Pyrrhus and of the martyrdom are given very fully and clearly in Hefele's *Conc.-gesch.*, vol. iii

MAXWELL, James Clerk (1831–1879), was the last representative of a younger branch of the well-known Scottish family of Clerk of Penicuik. He was educated at the Edinburgh Academy (1840–47) and the university of Edinburgh (1847–50). Entering at Cambridge in 1850, he spent a term or two in Peterhouse, but afterwards migrated to Trinity. He took his degree in 1854 as second wrangler, and was declared equal with the senior wrangler of his year in the higher ordeal of the Smith's prize examination. He held the chair of natural philosophy in Marischal College, Aberdeen, from 1856 till the fusion of the two colleges there in 1860. For eight years subsequently he held the chair of physics and astronomy in King's College, London, but resigned in 1868 and retired to his estate of Glenlair in Kirkcudbrightshire. He was summoned from his seclusion in 1871 to become the first holder of the newly-founded professorship of experimental physics in Cambridge; and it was under his direction that the plans of the Cavendish laboratory were prepared. He superintended every step of the progress of the building and of the purchase of the very valuable collection of apparatus with which it was equipped at the expense of its munificent founder the duke of Devonshire (chancellor of the university, and one of its most distinguished alumni). So far for the outline of Maxwell's career, as regards dates, official work, &c. The rest belongs almost exclusively to mathematical and physical science. For more than half of his brief life he held a prominent position in the very foremost rank of natural philosophers. His contributions to scientific societies began in his fifteenth year, when Professor J. D. Forbes communicated to the Royal Society of Edinburgh a short paper of his on a mechanical method of tracing Cartesian ovals. In his eighteenth year, while still a student in Edinburgh, he contributed two valuable papers to the *Transactions* of the same society—one of which, "On the Equilibrium of Elastic Solids," is remarkable, not only on account of its intrinsic power and the youth of its author, but also because in it he laid the foundation of one of the most singular discoveries of his later life, the temporary double refraction produced in viscous liquids by shearing stress. Immediately after taking his degree, he read to the Cambridge Philosophical Society a very novel memoir *On the Transformation of Surfaces by Bending*. This is one of the few purely mathematical papers he published, and it exhibited at once to experts the full genius of its author. About the same time appeared his elaborate memoir *On Faraday's Lines of Force*, in which he gave the first indication of some of those extraordinary electrical investigations which culminated in the greatest work of his life. He obtained in 1859 the Adams prize in Cambridge for a very original and powerful essay *On the Stability of Saturn's Rings*. From 1855 to 1872 he published at intervals a series of valuable investigations connected with the *Perception of Colour* and *Colour-Blindness*. For the earlier of these he received the Rumford medal in 1860. The instruments which he devised for these investigations were simple and convenient, but could not have been thought of for the purpose except by a man whose knowledge was co-extensive with his ingenuity. One of his greatest investigations bore on the *Kinetic Theory of Gases*. Originating with D. Bernoulli, this theory was advanced by the successive labours of Herapath, Joule, and particularly of Clausius, to such an extent as to put its general accuracy beyond a doubt. But by far the greatest developments it has received are due to Maxwell, part of whose mathematical work has recently been still further extended in some directions by Bolzmann. In this field Maxwell appears as an experimenter (on the laws of gaseous friction) as well as a mathematician. His two latest papers deal

with this branch of physics; one is an extension and simplification of some of Bolzmann's chief results, the other treats of the kinetic theory as applied to the motion of the radiometer. He has written an admirable text-book of the *Theory of Heat*, which has already (1882) gone through several editions, and a very excellent elementary treatise on *Matter and Motion*. Even this, like his other and larger works, is full of valuable matter, worthy of the most attentive perusal not of students alone but of the very foremost scientific men.

But the great work of his life was devoted to electricity. He began by reading with the most profound admiration and attention the whole of Faraday's extraordinary self-revelations, and proceeded to translate the ideas of that master into the succinct and expressive notation of the mathematicians. A considerable part of this translation was accomplished during his career as an undergraduate in Cambridge. The writer had the opportunity of perusing the MS. on *Faraday's Lines of Force*, in a form little different from the final one, a year before Maxwell took his degree. His great object, as it was also the great object of Faraday, was to overturn the idea of action at a distance. The splendid researches of Poisson and Gauss had shown how to reduce all the phenomena of statical electricity to mere attractions and repulsions exerted at a distance by particles of an imponderable on one another. Sir W. Thomson had, in 1846, shown that a totally different assumption, based upon other analogies, led (by its own special mathematical methods) to precisely the same results. He treated the resultant electric force at any point as analogous to the *flux of heat* from sources distributed in the same manner as the supposed electric particles. This paper of Thomson's, whose ideas Maxwell afterwards developed in an extraordinary manner, seems to have given the first hint that there are at least two perfectly distinct methods of arriving at the known formulæ of statical electricity. The step to magnetic phenomena was comparatively simple; but it was otherwise as regards electromagnetic phenomena, where current electricity is essentially involved. An exceedingly ingenious, but highly artificial, theory had been devised by Weber, which was found capable of explaining all the phenomena investigated by Ampère, as well as the induction currents of Faraday. But this was based upon the assumption of a distance-action between electric particles, whose intensity depended on their relative motion as well as on their position. This was, of course, even more repugnant to Maxwell's mind than the statical distance-action developed by Poisson. The first paper of Maxwell's in which an attempt at an admissible physical theory of electromagnetism was made was communicated to the Royal Society in 1867. But the theory, in a fully developed form, first appeared in his great treatise on *Electricity and Magnetism* (1873). This work, already in a second edition, is one of the most splendid monuments ever raised by the genius of a single individual. Availing himself of the admirable generalized coordinate system of Lagrange, Maxwell has shown how to reduce all electric and magnetic phenomena to stresses and motions of a material medium, and, as one preliminary, but excessively severe, test of the truth of his theory, has shown that (if the electromagnetic medium be that which is required for the explanation of the phenomena of light) the velocity of light in vacuo should be numerically the same as the ratio of the electromagnetic and electrostatic units. We do not as yet certainly know either of these quantities very exactly, but the means of the best determinations of each separately agree with one another more closely than do the various values of either. There seems to be no longer any possibility of doubt that Maxwell has taken the first grand step towards the discovery of the true nature of electrical phenomena. Had he done nothing but this, his fame would have been secured for all time. But, striking as it is, this forms only one small part of the contents of his truly marvellous work.

One of his last great contributions to science was his editing (with copious original notes) the *Electrical Researches of the Hon. Henry Cavendish*, which had been altogether unappreciated by the witlings to whom they had previously been confided. It now appears that Cavendish, already famous by many other researches (such as the mean density of the earth, the composition of water, &c.), must be looked on as, in his day, a man of Maxwell's own stamp as a theorist, and an experimenter of the very first rank.

This encyclopædia has been, in its scientific aspects, greatly indebted to Clerk Maxwell. The articles Atom, Attraction, Capillarity, Diffusion, Ether, &c., were intended as parts merely of one comprehensive system, in which a general résumé of all that is known of the properties of matter should be given in simple yet profound completeness. The reader of these articles cannot but feel how much has been lost when this splendid series cannot be completed by its initiator.

In private life Clerk Maxwell was one of the most lovable of men, a sincere and unostentatious Christian. Though perfectly free from any trace of envy or ill-will, he yet showed on fit occasion his contempt for that pseudo-science which seeks for the applause of the ignorant by professing to reduce the whole system of the universe to a fortuitous sequence of uncaused events.

His collected works will shortly be issued from the Pitt press; and an extended biography, by his former schoolfellow and lifelong friend Professor Campbell, has just been published (1882). (P. G. T.)

MAXWELL, Sir William Stirling-, Bart. (1818–1878), man of letters, the only son of Mr Archibald Stirling of Keir, Perthshire, and of Elizabeth, second daughter of Sir John Maxwell, seventh baronet of Pollok, Renfrewshire, was born at Kenmure, near Glasgow, in 1818. William Stirling was educated at Trinity College, Cambridge, where he graduated in 1839, and afterwards he spent some years on the Continent chiefly in France and Spain. Having succeeded his father as proprietor of Keir in 1846 (when he was made vice-lieutenant of Perthshire), he in 1852 entered parliament as member for that county; and he was several times re-elected. On the death of his uncle in 1865 he succeeded to the baronetcy and estates of Pollok, in respect of which he assumed the additional name of Maxwell. In the same year he became deputy-lieutenant of Lanarkshire, and a like office was conferred on him in Renfrewshire in 1870. The services which his talent, energy, and wealth enabled him to render to literature were recognized in a great variety of ways by numerous universities; in 1863 he was chosen lord rector of St Andrews, in 1871 the same honour was conferred by Edinburgh, and in 1875 he became chancellor of Glasgow. In the following year he was created a Knight of the Thistle, being the only commoner of the order. He died at Venice on January 15, 1878.

Sir W. Stirling-Maxwell's works, which are invariably characterized by thoroughness of workmanship and refinement of literary taste, were in some cases issued for private circulation only, and almost all of them are now exceedingly rare. They include an early volume of verse (*Songs of the Holy Land*, 1847), and several volumes containing costly reproductions of old engravings, along with valuable explanatory matter. His best-known publications are *Annals of the Artists of Spain* (1848; 2d ed., 1878), *The Cloister Life of Charles V.* (1852; 3d ed., 1853), and *Velazquez and his Works* (1855). A life of *Don John of Austria*, from his posthumous papers, is now (1882) in the press.

MAY, the fifth month of our modern year, was the third of the old Roman calendar. The name is of doubtful origin. Ovid (*Fasti*, v. 483–90) suggests the three derivations of

*majestas, majores* (the *patres* of the old Roman city), and *Maia*, the mother of Mercury, to whom the Romans were accustomed to sacrifice on the first day of the month. It was considered unlucky among the Romans to contract marriages during this month, on account of the celebration of the Lemuria,—a superstition of which traces are still to be found among ourselves. In the Roman Catholic Church May is known as "the month of Mary."

May-day is the name given to the first day of the month in England, when, according to ancient custom, all ranks of the people rose at early dawn and went out "a-Maying" to welcome the advent of spring. The customs of the day chiefly took their rise with the Romans. In the southern counties of England they differ materially from those of the northern and western. That of gathering branches of trees and flowers, to deck the person, is still observed in many places.

The May-Pole was once general throughout the country. The assemblage of the people, sanctioned by the presence of the priests, marching on May morning in procession to some neighbouring wood, returned in triumph with the pole, round which were suspended flowers, boughs, and other tokens of the spring season. On one of these festive occasions, Henry VIII. assembled his court at Shooter's Hill; and Queen Elizabeth also used to keep "May Games" at Greenwich. The May-pole, once fixed, often remained until nearly the end of the year; and there were some specially made of durable wood, which remained for many years, and were from time to time resorted to at other seasons of festivity. The last May-pole erected in London, 100 feet in height, was on the spot where the church in the Strand now stands, near Somerset House. Being taken down in 1717–18 it was conveyed to Wanstead Park in Essex, where it was fixed as part of the support of a large telescope set up by Sir Isaac Newton. The May Lady, Maulkin, Jack in the Green, and Morris Dancing are merely variations in the mode of representing the goddess Flora. The chimney sweepers, who are now the principal performers, are probably more interested than any other class in May sports. For, as the commencement of summer deprives them in a considerable degree of their business occupation, they naturally seek to avail themselves of the customary liberality of festive meetings.

The other principal fixed days observed and noted in the month are May 9, Half-Quarter-Day, and May 15, Whitsunday term,—not to be confounded with Whit Sunday, which is a movable feast.

MAYA. See MEXICO.

MAYBOLE, a burgh of barony and market-town of Scotland, in the county of Ayr, 9 miles south of Ayr on the railway to Stranraer, is built on the face of a hill gently sloping to the south. The characteristic features of the place are the old family mansions in the main street, the castle of the earls of Cassilis, and the old church ruins with the Cassilis burial-place. It has recently increased considerably in size, and it is now busy with various manufacturing industries in addition to its staple trade of shoemaking. The population was 3797 in 1871 and 4474 in 1881. New waterworks to supply 60,000 gallons daily were commenced in 1882; the site of the reservoir, about 3 miles south-east of the town, is almost that of the remarkable Lochspouts crannog (see *Ayr and Wigton Arch. and Hist. Collections*, vol. iii.; and Munro, *Ancient Scottish Lake Dwellings*, 1882).

A charter was granted to the town by Duncan in 1193; and the church was bestowed in 1216 on the Cistercian nunnery at North Berwick. In 1516 Maybole became a burgh of regality, and in 1639 the seat of the head courts of Carrick; but the independence of its local government was long contested by the superiors, the earls of Cassilis. Cotton weaving was introduced in the 18th century.

See J. Paterson, *History of Ayr and Wigton*, vol. ii., 1864.

MAYENCE. See MAINZ.

MAYENNE, a department of north-western France, three-fourths of which formerly belonged to Lower Maine and the remainder to Anjou, lies between 47° 45′ 10″ and 48° 34′ 30″ N. lat., and 0° 2′ E. and 1° 14′ W. long., and is bounded on the N. by Manche and Orne, on the E. by Sarthe, on the S. by Maine-et-Loire, and on the W. by Ille-et-Vilaine, having a maximum length from north to south of 51 miles, a breadth of 39 miles, and an area of 1996 square miles. Its ancient geological formations connect it with Brittany. The surface is agreeably undulated; forests are numerous, and the beauty of the cultivated portions is enhanced by the hedgerows and lines of trees by which the farms are divided. The highest point of the department, and indeed of the whole north-west of France, is the Mont des Avaloirs (1368 feet). Hydrographically Mayenne belongs to the basins of the Loire, the Vilaine, and the Sélune; the first-mentioned has the larger part of the entire area. The principal stream is the Mayenne, which passes successively from north to south through the three most important towns—Mayenne, Laval, and Château-Gontier; by means of weirs and sluices it is navigable below Mayenne, but steamers do not ascend past Château-Gontier. The chief affluents are the Jouanne on the left, and on the right the Colmont, the Ernée, and the Oudon. A small area in the east of the department drains by the Erve into the Sarthe; the Vilaine rises in the west, and in the north-west the Sélune flows into the English Channel. The climate of Mayenne, which is that of the Sequanian region, is generally healthy except in the neighbourhood of the numerous marshes. The temperature is lower and the moisture of the atmosphere greater than in the neighbouring departments; the rainfall is above the average for France.

Of the entire area two-thirds are arable, and a twentieth is under wood. A large number of horned cattle are reared (98,000 oxen, 150,000 cows), and in no other French department are so many horses (92,500) found within the same area; the breed, that of Craon, is famed for its strength. Craon has also given its name to the most prized breed of pigs in western France. There are 83,000 pigs in the department, 80,000 sheep, and 5000 goats. Mayenne produces excellent butter, poultry, and game, and a large quantity of honey. The cultivation of the vine is very limited, and the most common beverage is cider, of which nearly 9,000,000 gallons are annually made. Agriculture is in a flourishing condition; in 1878 were produced upwards of 3½ million bushels of wheat, ⅔ million of meslin, nearly an equal amount of rye, 1½ million of barley, 2 million of oats, and nearly 3 million bushels of potatoes, besides a large quantity of flax and hemp. The timber grown is chiefly beech, oak, birch, elm, and chestnut. The department produces a little iron-ore and manganese; it is rich in anthracite and coal, of which, however, the annual production has recently decreased from 80,000 tons to 60,000. Marble and granite, limestone, slate, and porphyry are quarried; the last-named material is capable of a fine polish, and is also used for paving the streets of Paris. There are several chalybeate springs. The industries include iron and brass founding, brick and tile making, brewing, the manufacture of candles, cotton, linen, and woollen thread, and the production of various textile fabrics (that of ticking being the specialty of the department), agricultural implement making, wood and marble sawing, tanning, dyeing, and the like. The population in 1881 was 343,167. The arrondissements are those of Laval, Château-Gontier, and Mayenne.

MAYENNE, capital of an arrondissement in the above department of France, is an old feudal town irregularly built on two hillocks which overlook the river Mayenne, at the point where the railway from Caen to Laval is joined by that from Fougères to Alençon. The old castle still has towards the river five towers, one of which has retained its conical roof; the vaulted chambers and chapel are ornamented in the style of the 13th century; the building is now used as a prison. The church of Notre Dame, dating partly from the 12th century, is the only other building of any special interest. In the Place de Cheverus is a statue, by David of Angers, to the cardinal of that name, who was born in Mayenne. The chief

industry of the place is the cloth manufacture, which occupies 8000 persons in the town and neighbourhood. The population in 1876 was 10,098.

Mayenne had its origin in the castle built here by Juhel, the son of Geoffroy of Maine, in the beginning of the 11th century. It was besieged by William the Conqueror, and afterwards by the earl of Salisbury; and the possession of it was disputed by the Royalists and the Leaguers, as also by the Republicans and the Vendeans.

MAYER, JOHANN TOBIAS (1723–1762), one of the greatest of last century's astronomers, was born at Marbach in Würtemberg, February 17, 1723. He was brought up at Essliugen in comparatively poor circumstances, and as a mathematician was mainly self-taught. He had already published several original geometrical tracts when, in 1746, he entered Homann's cartographic establishment at Nuremberg. Here he introduced many improvements in map-making, and gained a scientific reputation which led (in 1751) to his election to the chair of economy and mathematics in the university of Göttingen. In 1754 he became superintendent of the observatory, where he laboured with great zeal and success till his death, February 20, 1762. His first important astronomical work was a careful investigation of the libration of the moon (*Kosmographische Nachrichten*, Nuremberg, 1750), the elements of which and the position of the moon's axis of rotation he determined with much greater accuracy than had previously been done. His great fame rests on his lunar tables, which were published in 1753 along with new solar tables, and transmitted to England in 1755. These tables, which were compared by Bradley with the Greenwich observations, and found to be sufficiently accurate to determine the longitude at sea to within half a degree, solved the problem of practically determining longitude anywhere on the earth's surface. An improved set was afterwards published in London (1770), as also the theory (*Theoria Lunæ juxta Systema Newtonianum*, 1767) upon which the tables are based. They were sent to England by his widow, who in consideration received from the British Government a grant of £3000. Appended to the London edition of the solar and lunar tables are two short tracts, —the one on determining longitude by lunar distances, together with a description of the repeating circle (invented by Mayer in 1760), the other on a formula for atmospheric refraction, which applies a remarkably accurate correction for temperature.

Mayer left behind him a considerable quantity of manuscript, part of which was collected by Lichtenberg and published in one volume (*Opera Inedita*, Göttingen, 1775) It contains, amongst other papers, an easy and accurate method for calculating eclipses; an essay on colour, in which three primary colours are recognized; a catalogue of nine hundred and ninety-eight zodiacal stars; and a memoir, the earliest of any real value, on the proper motion of fixed stars, which was originally communicated to the Göttingen Royal Society in 1760. The other part still remains in manuscript, and includes papers on atmospheric refraction (dated 1755), on the motion of Mars as affected by the perturbations of Jupiter and the Earth (1756), and on terrestrial magnetism (1760 and 1762). In these last Mayer seeks to explain the magnetic action of the earth by a simple hypothesis. He supposes a small bar-magnet to be placed with its centre at the earth's centre, and calculates the position of equilibrium of a second small magnet at any given point on the earth's surface, assuming the law of magnetic attraction and repulsion to be that of the inverse square. Though the values of the declination and dip calculated according to this theory do not agree with the observed values, Mayer must be credited with the first really definite attempt to establish a mathematical theory of magnetic action, and as the first who gave any experimental evidence in favour of the inverse square of the distance as the law of force. See Hansteen's *Magnetismus der Erde*.

MAYER, JULIUS ROBERT (1814–1878), was born at Heilbronn, Nov. 25, 1814, studied medicine at Tübingen, Munich, and Paris, and, after a journey to Java in 1840 as surgeon of a Dutch vessel, obtained a medical post in his native town. He claims recognition as an independent *a priori* propounder of the "First Law of Thermodynamics," but more especially as having early and ably applied that law to the explanation of many remarkable phenomena, both cosmical and terrestrial. His first little paper on the subject, "Bemerkungen über die Kräfte der unbelebten Natur," appeared in 1842 in Liebig's *Annalen*, five years subsequent to the republication, in the same journal, of an extract from the great memoir of MOHR (*q.v.*). Mayer's statements as to the "indestructibility of force" (as he calls it) were based almost entirely upon scholastic dicta, such as *causa æquat effectum*, &c. The main experimental fact which he adduces in support of his reasoning as to the convertibility of work and heat is a mere repetition, in a very inadequate form, of a curious experiment made by Dr Reade of Cork, who found (*Nicholson's Journal*, XX., 1808, p. 113) that water was sensibly heated after being violently shaken in a phial. But Dr Reade states explicitly the precautions he had taken to protect the phial and its contents from heating by the hand of the operator,—an important detail which is unnoticed by Mayer.

It has been repeatedly claimed for Mayer that he calculated the value of the dynamical equivalent of heat, indirectly no doubt, but in a manner altogether free from error, and with a result according almost exactly with that obtained by Joule after years of patient labour in direct experimenting. Mayer assumed that the heat developed by compression of air is the equivalent of the work spent in the compression. If we had independent proof of this the result would undoubtedly follow.[1] And it has been urged that the man who, by a single burst of genius, reached at once the goal which others had been painfully seeking, merits an amount of fame commensurate with that due to discoverers like Newton or Galileo. This claim on Mayer's behalf was first shown to be baseless by Thomson and Tait ("Energy," *Good Words*, 1862). This article gave rise to a long but lively discussion. A calm and judicial annihilation of the claim is to be found in a brief article by Stokes, *Proc. Roy. Soc.*, 1871, p. 54. See also Maxwell's *Theory of Heat*, chap. xiii. Mayer entirely ignored the grand fundamental principle laid down by Sadi Carnot, a principle which has done even more for physics than has the conservation of energy itself, viz., that nothing can be concluded as to the relation between heat and work from an experiment in which the working substance is left at the end of an operation in a different physical state from that in which it was at the commencement. Mayer has also been styled the discoverer of the fact that heat consists in (the energy of) motion, a matter settled at the very end of the 18th century by Rumford and Davy. In the teeth of this statement we have Mayer's own words, "We might much rather assume the contrary, —that in order to become heat, motion must cease to be motion."

Mayer's real merit consists in the fact that, having for himself made out, on inadequate and even questionable grounds, the conservation of energy, and having obtained (though by inaccurate reasoning) a numerical result correct so far as his data permitted, he applied the principle with great power and insight to the explanation of numerous physical phenomena. His papers, which have been republished in a single volume with the title *Die Mechanik der Wärme* (2d ed., Stuttgart, 1874), are of extremely unequal merit. But some, especially those on *Celestial Dynamics* and *Organic Motion*, are admirable examples of what really valuable work may be effected by a man of high intellectual powers, in spite of imperfect information and defective logic.

Different, and, it would appear, exaggerated, estimates of Mayer are given in Dr Tyndall's papers in the *Phil. Mag.*, 1863–64 (whose avowed object was "to raise a noble and a suffering man to the position which his labours entitled him to occupy"), and in the extraordinary treatise by Dühring, *Robert Mayer, der Galilei des neunzehnten Jahrhunderts*, Chemnitz, 1880. Some of the simpler facts of the case are summarized by Tait in the *Phil. Mag.*, 1864, ii. p. 289.

MAYHEM (MAIM), an old term of the law signifying an assault whereby the injured person is deprived of a member proper for his defence in fight, *e.g.*, an arm, a leg, a fore tooth, &c. The loss of an ear, jaw tooth, &c., was not mayhem. The most ancient punishment in English law was retaliative—*membrum pro membro*, but ultimately at common law fine and imprisonment. Various statutes were passed aimed at the offence of maiming and dis-

[1] Séguin, three years before, had assumed that the work done by steam or any other expanding substance is the equivalent of the heat which disappears during the expansion. A similar idea, but more accurately expressed, is to be found in Mohr's paper, above referred to.

figuring, which is now dealt with by section 18 of 24 & 25 Vict. c. 100. Mayhem may also be the ground of a civil action, which had this peculiarity that the court on sight of the wound might increase the damages awarded by the jury.

MAYKOP, a town of the Caucasus, Russia, in the province of Kuban, on the Byelaya, a tributary of the Kuban, 93 miles to the south-east of Yekaterinodar, the capital of the province. Formerly it was merely a fortified "stanitsa" (village of Cossacks) and the centre for military operations against western Caucasus. But, owing to its position in a very fertile country where settlers from Russia found plenty of rich soil which had been abandoned by the natives, Maykop has become a wealthy town, and its population has rapidly increased to 22,550. Most of them are still agriculturists, but others are engaged in a brisk trade in the produce obtained from the large and wealthy stanitsas of the surrounding district.

MAYNOOTH, a village in the county of Kildare, province of Leinster, Ireland, is situated on the Royal Canal and on the Midland Great Western Railway, 15 miles north-west of Dublin. The Royal Catholic College of Maynooth, instituted by the Irish parliament in 1765, is the chief seminary for the education of the Roman Catholic clergy of Ireland. It was supported by a parliamentary grant of £26,000 a year, which at the disestablishment of the Irish Church in 1869 was commuted by the payment of a capital sum fourteen times its amount. The building is a fine Gothic structure by Pugin, erected by a parliamentary grant obtained in 1846. Near the college stand the ruins of Maynooth Castle, built in 1426, and formerly the residence of the Fitzgerald family. It was besieged in the reign of Henry VIII., in that of Edward VI., and during the Cromwellian wars, when it was demolished. The beautiful mansion of the duke of Leinster is about a mile from the town.

MAYO, a maritime county on the west coast of Ireland, province of Connaught, is bounded N. and W. by the Atlantic Ocean, N.E. by Sligo, E. by Roscommon, S.E. and S. by Galway. Its greatest length from north to south is about 75 miles, and its greatest breadth about 65 miles. The total area is 1,318,129 acres, or 2060 square miles.

About two-thirds of the boundary of Mayo is formed by sea, and the coast is very much indented, and abounds in picturesque scenery. The principal inlets are Killary Harbour between Mayo and Galway; Clew Bay, in which are the harbours of Westport and Newport; Blacksod Bay and Broad Haven, which form the peninsula of the Mullet; and Killala Bay between Mayo and Sligo. The islands are very numerous, the principal being Inishturk (area 1445 acres, and population 132 in 1881), near Killary Harbour; Clare Island (area 3949 acres, population 62) at the mouth of Clew Bay, where there are many islets all formed of drift; and Achil (area 35,838 acres, population 5070), the largest island in Ireland. In the eastern half of the county, where Carboniferous rocks prevail, the surface is comparatively level, with occasional hills consisting chiefly of granite and slate. The western half is very mountainous, but there are a few valleys adjoining the sea-shore. A great portion of the coast extending from Killala to Clew Bay consists of Old Red and Yellow Sandstone. The remainder of the mountainous region consists chiefly of quartzite or alternating beds of quartzite and granite or gneiss schist. Muilrea (2688 feet) is included in a mountain range, lying between Killary Harbour and Lough Mask, which belongs to the Upper Silurian formation. The next highest summits are Nephin (2530 feet), to the west of Lough Conn, and Croagh Patrick (2370 feet), to the south of Clew Bay. The river Moy flows northwards, forming the boundary of the county with Sligo, and falls into Killala Bay. The courses of the other streams are short, and except when swollen by rains their volume is small. The principal lakes are Lough Mask and Lough Corrib, on the borders of the county with Galway, and Loughs Conn, Carrah, Castlebar, Cullin, and Carrowmore. Limestone is abundant, and also iron ore, which, however, is not smelted, from want of fuel. There are several valuable slate quarries; and ochres, granite, and manganese are found.

*Agriculture.*—There are some very fertile regions in the level portions of the county, but in the mountainous districts the soil is poor, the holdings are subdivided beyond the possibility of affording proper sustenance to their occupiers, and, except where fishing is combined with agricultural operations, the circumstances of the peasantry are among the most wretched of any district of Ireland.

In 1881 there were 179,343 acres, or less than one-eighth of the whole area, under crops, while 545,040 were pasture, 10,702 woods, and 521,673 waste. The total number of holdings in 1881 was 37,693, of which 22,914 were less than 15 acres in extent, and 9386 between 15 and 30 acres. The following table shows the areas under the principal crops in 1855 and 1882:—

| | Wheat. | Oats. | Other Cereals. | Potatoes. | Turnips. | Other Green Crops. | Flax. | Meadow and Clover. | Total. |
|---|---|---|---|---|---|---|---|---|---|
| 1855 | 4,638 | 83,543 | 5,396 | 59,037 | 9,556 | 2,193 | 745 | 18,229 | 183,337 |
| 1882 | 1,083 | 61,125 | 3,016 | 54,594 | 7,960 | 8,964 | 286 | 43,363 | 175,391 |

Horses between 1855 and 1882 increased from 17,531 to 18,050, of which 12,150 were used solely for agricultural purposes. The number of cattle in 1855 was 153,583, and in 1882 it was 162,331, of which 53,153 were milch cows. Sheep in 1855 numbered 265,448, and in 1882 only 225,509, although in 1880 there were as many as 271,282. Pigs in 1882 numbered 62,227, goats 5987, and poultry 632,432. According to the latest return the land was divided among 1483 proprietors, who possessed 1,308,367 acres, at an annual rateable value of £310,140, the rateable value per acre being 4s. 8d. The average size of the properties was 882 acres. No fewer than 21 proprietors, possessed upwards of 10,000 acres, and of these 8 possessed upwards of 20,000, viz., Marquis of Sligo, 114,881 acres; Viscount Dillon, 83,749; Sir R. W. H. Palmer, Bart., 80,990; Earl of Lucan, 60,570; T. S. Carter, 37,773; G. Clive, 35,229; Earl of Arran, 29,644; C. H. Knox, 24,374.

*Manufactures and Trade.*—Coarse linen and woollen cloths are manufactured to a small extent. There are very productive fishing banks on the coast, especially in the neighbourhood of the islands, and the Moy is a fine river for salmon.

*Railways.*—The Great Northern and Western Railway crosses the county from near Ballyhaunis to Westport, and a branch from it runs north to Ardnaree near Killala Bay.

*Administration and Population.*—The county includes nine baronies and seventy-three parishes. It is in the Connaught circuit. Assizes are held at Castlebar, and quarter sessions at Ballina, Ballinrobe, Bellmullet, Castlebar, Claremorris, Swineford, and Westport. There are twenty-two petty sessions districts within the county, and portions of two other districts. It includes the seven poor-law unions of Bellmullet, Castlebar, Claremorris, Killala, Newport, Swineford, and Westport, and part of the unions of Ballina, Ballinrobe, and Castlerea. It is in the Dublin military district, subdistrict of Galway; and there are barrack stations at Castlebar, Ballinrobe, Westport, Foxford, and Ballaghaderreen. In the Irish parliament two members were returned for the county, and two for the borough of Castlebar, but at the Union Castlebar was disfranchised.

From 77,508 in 1760 the population gradually increased till in 1841 it was 388,887, but in 1851 it had diminished to 274,499, in 1871 to 246,030, and in 1881 to 245,212, of whom 119,421 were males and 125,791 females. The county contains a portion (with 4318 inhabitants) of the township of Ballina, the townships of Castlebar, 3855, and Westport, 4469, and the town of Ballinrobe, 2286. The number of emigrants from 1st May 1851 to 31st December 1881 was 85,431. The number of emigrants in 1881 was 4469, or a proportion of 18·4 to every 1000 of the population. The death-rate to every 1000 of the population for 10 years ending 31st March 1881 was 13·8, the birth-rate 27·1, and the marriage-rate 3·9. Roman Catholics in 1881 numbered 238,262, Episcopalians 5575, Presbyterians 925, and Methodists 275. In 1881 as many as 8808 persons could speak Irish only, and 138,930 Irish and English.

*History and Antiquities.*—The name given by Ptolemy to the inhabitants of this district of Ireland was Nagnatæ. Erris in Mayo was the scene of the landing of the chief colony of the Firbolgs, and the battle which is said to have resulted in the overthrow

and almost annihilation of this tribe took place also in this county, at Moytura near Cong. Along with the greater part of Connaught it was granted by King John to Hubert de Burgo, but after the rebellion against William de Burgo, third earl, headed by Mac William Oughter, the whole province of Connaught remained nearly independent of British rule till the time of Elizabeth. In the eleventh year of her reign Mayo was made shire ground, taking its name from the monastery of Maio or Mageo, which was the see of a bishop. Even, however, after this period the Mac Williams continued to exercise very great authority. Large confiscations of the estates in the county were made in 1586, on the termination of the wars of 1641, and after the restoration of the Stuarts. Killala was the scene of the landing of a French squadron in connexion with the rebellion of 1798.

There are four round towers in the county,—at Killala, Turlogh, Meelick, and Bal or Ballagh. The monasteries were numerous, and many of them of considerable importance—the principal being those at Mayo, Ballyhaunis, Cong, Ballinrobe, Ballintober, Burrishoole, Cross or Holycross in the peninsula of Mullet, Moyne, Rosserick, and Strade. Of the old castles the most notable are Downpatrick, on a cliff 300 feet in height projecting into the sea, Rockfleet near Newport, said to have been built by the celebrated Grace O'Malley, Ballylahan Castle near Foxford, and Deel Castle near Ballina, at one time the residence of the earls of Arran.

MAYOR. See MUNICIPALITY.

MAYOTTA. See COMORES, vol. vi. p. 220.

MAYSVILLE, a city of the United States, the capital of Mason county, Kentucky, lies on the south bank of the Ohio, 69 miles north-east of Lexington by rail. Settled in 1784 and incorporated in 1833, it has grown into a busy place of 5220 inhabitants (1880), with several good public buildings, flour-mills, plough-factories, &c., and is one of the principal hemp-markets in the States.

MAZAMET, an industrial town in the department of Tarn, France, stands on the northern slope of the Montagnes Noires (part of the Cevennes), and on the Arnette, a tributary of the Tarn by the Agout. In last century it was an insignificant village, but at present it has 14,000 inhabitants, an increase of prosperity due to the introduction by M. Houlès (whose statue stands in the public square) of the manufacture of a particular kind of woollen fabric sold almost exclusively in France. The factories, driven by water-power, have a total of 45,000 spindles, and an annual turnover of from 15 to 18 millions of francs. Mazamet is connected by a branch line of railway with the town of Castres.

MAZÁNDARÁN, a province of northern Persia, lying between the Caspian Sea and the Elbúrz range, and bounded E. and W. by the provinces of Astrábád and Gílán respectively, is 220 miles in length and 60 miles in (mean) breadth, with an area of about 10,000 square miles and a population estimated at from 150,000 to 200,000. Mazandarán comprises two distinct natural regions presenting the sharpest contrasts in their relief, climate, and products. In the north the Caspian is encircled by the level and swampy lowlands, varying in breadth from 10 to 30 miles, partly under impenetrable jungle, partly under rice, cotton, sugar, and other crops. This section is fringed northwards by the sandy beach of the Caspian, here almost destitute of natural harbours, and rises somewhat abruptly inland to the second section, comprising the northern slopes and spurs of the Elbúrz, which approach at some points within 1 or 2 miles of the sea, and which are almost everywhere covered with dense forest. The lowlands, rising but a few feet above the Caspian, and subject to frequent floodings, are extremely malarious, while the highlands, culminating with the magnificent Damávand (18,600 feet), enjoy a tolerably salubrious climate. But the climate, generally hot and moist in summer, is everywhere capricious and liable to sudden changes of temperature, whence the prevalence of rheumatism, dropsy, and especially ophthalmia, noticed by all travellers. Snow falls heavily on the uplands, where it often lies for weeks on the ground. The direction of the long sandbanks at the river mouths, which project with remarkable uniformity from west to east, shows that the prevailing winds blow from the west and north-west. The rivers themselves, of which there are as many as fifty, are little more than mountain torrents, all rising on the northern slopes of Elbúrz, flowing mostly in independent channels to the Caspian, and subject to sudden freshets and inundations along their lower course. The chief are the Safed-rúd on the Gílán frontier, the Lár, Hari-rúd, Alam-rúd, Rústam-rúd, and Hárez, and all are well stocked with trout, mullet (safed máhí), carp, sturgeon, and other fish, which with rice form the staple food of the inhabitants, and supply large quantities of caviare for the Russian market. Near their mouths the rivers, running counter to the prevailing winds and waves of the Caspian, form long sand-hills 20 to 30 feet high and about 200 yards broad, behind which are developed the so-called *múrd-áb*, or "dead waters," stagnant pools and swamps characteristic of this coast, and a chief cause of its unhealthiness.

The province abounds in iron ores and in mineral pitch in every state of transition from pure petroleum to the finest naphtha. The chief cultivated plants are rice, cotton, sugar, a little silk, and fruits in great variety, including several kinds of the orange, lemon, and citron. Some of the slopes are covered with extensive thickets of the pomegranate, and the wild vine climbs to a great height round the trunks of the forest trees. These woodlands are haunted by the tiger, panther, bear, wolf, and wild boar in considerable numbers. Of the domestic animals, all remarkable for their small size, the chief are the black, humped cattle somewhat resembling the Indian variety, the yabu (a sturdy breed of horses), and sheep and goats.

Kinneir, Frazer, and other observers speak unfavourably of the Mazandaráni people, whom they describe as very ignorant and bigoted, arrogant, rudely inquisitive, and almost insolent towards strangers. The peasantry, however, although called the "Bœotians of Persia," are far from dull, and betray much shrewdness where their interests are concerned. In the healthy districts they are stout and well made, and are the most warlike race in Persia, furnishing 5000 cavalry and 12,000 foot to the Government. Of the latter 2000 are always in attendance on the shah at Tehrán. They speak a marked and somewhat rude Persian dialect; but a Túrki idiom closely akin to the Turkoman is still current amongst the foreign tribes, although they have mostly already passed from the nomad to the settled state. Of these intruders the most numerous are the Modaunlú, Khojehvand, and Abdul Maleki, originally of Lek or Kurd stock, besides branches of the royal Afshár and Kájár tribes of Túrki descent. All these are exempt from taxes in consideration of their military service.

The export trade is chiefly with Russia through Bákú, where broadcloths, flour, saffron, and bar iron are taken in exchange for the white and coloured calicoes, caviare, rice, and raw cotton of Mazandarán. Owing to the almost impenetrable character of the country, there are scarcely any roads accessible to wheeled carriages, and the great causeway of Shah Abbas has in many places even disappeared under the jungle. Two routes, however, lead to Tehrán, one by Firoz Koh, 180 miles long, the other by Lariján, 144 miles long, both in tolerably good repair. Except where crossed by these routes the Elbúrz forms an almost impassable barrier to the south.

The administration is in the hands of the prince governor, who appoints most of the beglerbegs and governors of the nine districts of Amól, Bárfarósh, Mashhad-i-Sar, Sárí, Ashraf, Farah-ábád, Tennacorben, Kellauristak, and Kújúr into which the province is divided. There is fair security for life and property; and, although otherwise indifferently administered, the country is quite free from marauders or local disturbances. The revenue is about 105,000 tománs, of which nothing goes to the state treasury, all being required for the governors, troops, pensions, and police. The capital is Sárí, the other chief towns being Bárfarósh, Mashhad-i-Sar, Ashraf, and Farah-ábád.

MAZARIN, JULES (1602–1661), cardinal, the successor of Richelieu, and forerunner of Louis XIV., was the elder son of Pietro Mazarini, the intendant of the household of Philip Colonna, and of his wife Ortensia Buffalini, a connexion of the Colonnas, and was born at Piscina in the Abruzzi on July 14, 1602. He was educated by the Jesuits at Rome till his seventeenth year, when he accom-

panied Jerome Colonna as chamberlain to the university of Alcala in Spain. There he distinguished himself more by his love of gambling and his gallant adventures than by study, but made himself a thorough master, not only of the Spanish language and character, but also of that romantic fashion of Spanish love-making which was to help him greatly in after life, when he became the servant of a Spanish queen. On his return to Rome he took his degree as Doctor Utriusque Juris, and then became captain of infantry in the regiment of Colonna, which took part in the war in the Valtelline. During this war he gave proofs of much diplomatic ability, and Pope Urban VIII. entrusted him, in 1629, with the difficult task of putting an end to the war of the Mantuan succession. His success marked him out for further distinction. He was presented to two canonries in the churches of St John Lateran and Sta Maria Maggiore, although he had only taken the minor orders, and had never been consecrated priest; he negotiated the treaty of Turin between France and Savoy in 1632, became vice-legate at Avignon in 1634, and nuncio at the court of France from 1634–36. But he began to wish for a wider sphere than papal negotiations, and, seeing that he had no chance of becoming a cardinal except by the aid of some great power, he accepted Richelieu's offer of entering the service of the king of France, and in 1639 became a naturalized Frenchman. In 1640 Richelieu sent him to Savoy, where the regency of Christine, the duchess of Savoy, and sister of Louis XIII., was disputed by her brothers-in-law, the princes Maurice and Thomas of Savoy, and he succeeded not only in firmly establishing Christine but in winning over the princes to France. This great service was rewarded by his promotion to the rank of cardinal on the presentation of the king of France in December 1641. On the 4th December 1642 Cardinal Richelieu died, and on the very next day the king sent a circular letter to all officials ordering them to send in their reports to Cardinal Mazarin, as they had formerly done to Cardinal Richelieu. Mazarin was thus acknowledged supreme minister, but he still had a difficult part to play. The king evidently could not live long, and to preserve power he must make himself necessary to the queen, who would then be regent, and do this without arousing the suspicions of the king or the distrust of the queen. His measures were ably taken, and when the king died on May 14, 1643, to every one's surprise her husband's minister remained the queen's. The king had by a royal edict cumbered the queen-regent with a council and other restrictions, and it was necessary to get the parlement of Paris to overrule the edict, and make the queen absolute regent, which was done with the greatest complaisance. Now that the queen was all-powerful, it was expected she would at once dismiss Mazarin and summon her own friends to power. One of them, Potier, bishop of Beauvais, already gave himself airs as prime minister, but Mazarin had had the address to touch both the queen's heart by his Spanish gallantry and her desire for her son's glory by his skilful policy abroad, and he found himself able easily to overthrow the clique of Importants, as they were called. That skilful policy was shown in every arena on which the great Thirty Years' War was being fought out. Mazarin had inherited the policy of France during the Thirty Years' War from Richelieu. He had inherited his desire for the humiliation of the house of Austria in both its branches, his desire to push the French frontier to the Rhine and maintain a counterpoise of German states against Austria, his alliances with the Netherlands and with Sweden, and his four theatres of war—on the Rhine, in Flanders, in Italy, and in Catalonia. This is not the place to examine the campaigns of the last five years of the great war (see CONDÉ, TURENNE), but it was Mazarin alone who directed the French diplomacy of the period. He it was who made the peace of Brömsebro between the Danes and the Swedes, and turned the latter once again against the empire; he it was who sent Lionne to make the peace of Castro, and combine the princes of North Italy against the Spaniards, and who made the peace of Ulm between France and Bavaria, thus detaching the emperor's best ally. He made one fatal mistake,—he dreamt of the French frontier being the Rhine and the Scheldt, and that a Spanish princess might bring the Spanish Netherlands as dowry to Louis XIV. This roused the jealousy of the United Provinces, and they made a separate peace with Spain in January 1648; but the valour of the French generals made the skill of the Spanish diplomatists of no avail, for Turenne's victory at Zusmarshausen, and Condé's at Lens, caused the peace of Westphalia to be definitely signed in October 1648. This celebrated treaty belongs rather to the history of Germany than to a life of Mazarin: but two questions have been often asked, whether Mazarin did not delay the peace as long as possible in order to more completely ruin Germany, and whether Richelieu would have made a similar peace. To the first question Mazarin's letters, published by M. Cheruel, prove a complete negative, for in them appears the zeal of Mazarin for the peace. On the second point, Richelieu's letters in many places indicate that his treatment of the great question of frontier would have been more thorough, but then he would not have been hampered in France itself.

We must now notice that strange period of the Fronde which has always been variously treated, for modern historians have written its history from many different standpoints, all of which can be categorically supported from the varying mémoires of the principal actors. Now, however, thanks to the labours of M. Cousin on the *carnets* of Mazarin, which contain the substance of his inmost thoughts, and of M. Cheruel on the letters written to and by Mazarin, it is possible to construct a more accurate and trustworthy history of the Fronde than has ever yet been attempted. It is not, however, intended here to trace the whole history of the Fronde, interesting as that would be, but merely to trace the policy of Mazarin throughout the epoch. The origin of both the Frondes was partly Mazarin's fault. In 1645 the parlement of Paris had protested against certain taxes, and had been checked by a *lit de justice*; and when, in 1648, it united its members in the Chambre de Saint Louis for the general reform of the kingdom, Mazarin and the queen, instead of holding another *lit de justice*, calling the states-general, or transferring the parlement out of Paris, any of which measures would have broken its power, foolishly believed in the influence of the victory of Lens, and threw the people of Paris on the side of the parlement by the arrest of Broussel. The Fronde of the princes and the nobles, on the other hand, was largely due to Mazarin's absorption of political power. These Frondeurs were not, like their ancestors, moved by great religious and political sympathies, but by merely selfish aims for restoring the old licence of duel and intrigue, and were only united in one sentiment, hatred to Mazarin. That this was so was greatly Mazarin's own fault; he had tried consistently to play off Gaston of Orleans against Condé, and their respective followers against each other, and had also, as his *carnets* prove, jealously kept any courtier from getting into the good graces of the queen-regent except by his means, so that it was not unnatural that the nobility should hate him, while the queen found herself surrounded by his creatures alone. Events followed each other quickly; the day of the barricades was followed by the peace of Ruel, the peace of Ruel by the arrest of the princes, by the battle of Rethel, and Mazarin's exile to Brühl before the union of the two

Frondes. It was while in exile at Brühl that Mazarin saw the mistake he had made in isolating himself and the queen, and that his policy of balancing every party in the state against each other had made every party distrust him. So by his counsel the queen, while nominally in league with De Retz and the parliamentary Fronde, laboured to form a purely royal party, wearied by civil dissensions, who should act for her and her son's interest alone, under the leadership of Mathieu Molé, the famous premier president of the parlement of Paris. The new party grew in strength, and in January 1652, after exactly a year's absence, Mazarin returned to the court. Turenne had now become the royal general, and out-manœuvred Condé, while the royal party at last grew to such strength in Paris that Condé had to leave the capital and France. In order to promote a reconciliation with the parlement of Paris, Mazarin had again retired from court, this time to Sedan, in August 1652, but he returned finally in February 1653. Long had been the trial, and greatly had Mazarin been to blame in allowing the Frondes to come into existence, but he had retrieved his position by founding that great royal party which steadily grew until Louis XIV. could fairly have said "L'État, c'est moi." As the war had progressed, Mazarin had steadily followed Richelieu's policy of weakening the nobles on their country estates. Whenever he had an opportunity he destroyed a feudal castle, and by destroying the towers which commanded nearly every town in France, he freed such towns as Bourges, for instance, from their long practical subjection to the neighbouring great lord.

The Fronde over, Mazarin had to build up afresh the power of France at home and abroad. It is to his shame that he did so little at home. Beyond destroying the brick and mortar remains of feudalism, he did nothing for the people. But abroad his policy was everywhere successful, and opened the way for the policy of Louis XIV. He at first, by means of an alliance with Cromwell, recovered the north-western cities of France, though at the price of yielding Dunkirk to the Protector. On the Baltic, France guaranteed the treaty of Oliva between her old allies Sweden, Poland, and Brandenburg, which preserved her influence in that quarter. In Germany he, through Lionne, formed the league of the Rhine, by which the states along the Rhine bound themselves under the headship of France to be on their guard against the house of Austria. By such measures Spain was induced to sue for peace, which was finally signed in the Isle of Pheasants on the Bidassoa, and which is known as the treaty of the Pyrenees. By it Spain recovered Franche Comté, but ceded to France Roussillon, and much of French Flanders; and, what was of greater ultimate importance to Europe, Louis XIV. was to marry a Spanish princess, who was to renounce her claims to the Spanish succession if her dowry was paid, which Mazarin knew could not happen at present from the emptiness of the Spanish exchequer. He returned to Paris in declining health, and did not long survive the unhealthy sojourn on the Bidassoa; after some political instruction to his young master, he passed away at Vincennes on March 9, 1661, leaving a fortune estimated at from 18 to 40 million livres behind him, and his nieces married into the greatest families of France and Italy.

The man who could have had such success, who could have made the treaties of Westphalia and the Pyrenees, who could have weathered the storm of the Fronde, and left France at peace with itself and with Europe to Louis XIV., must have been a great man; and historians, relying too much on the brilliant memoirs of his adversaries, like De Retz, are apt to rank him too low. That he had many a petty fault there can be no doubt; that he was avaricious and double-dealing was also undoubted; and his *carnets* show to what unworthy means he had recourse to maintain his influence over the queen. What that influence was will be always debated, but both his *carnets* and the Brühl letters show that a real personal affection, amounting to passion on the queen's part, existed. Whether they were ever married may be doubted; but that hypothesis is made more possible by M. Cheruel's having been able to prove from Mazarin's letters that the cardinal himself had never taken more than the minor orders, which could always be thrown off. With regard to France he played a more patriotic part than Condé or Turenne, for he never treated with the Spaniards, and his letters show that in the midst of his difficulties he followed with intense eagerness every movement on the frontiers. It is that immense mass of letters, now in course of publication, that prove the real greatness of the statesman, and disprove De Retz's portrait, which is carefully arranged to show off his enemy against the might of Richelieu. To concede that the master was the greater man and the greater statesman does not imply that Mazarin was but a foil to his predecessor. It is true that we find none of those deep plans for the internal prosperity of France which shine through Richelieu's policy. Mazarin was not a Frenchman, but a citizen of the world, and always paid most attention to foreign affairs; in his letters all that could teach a diplomatist is to be found, broad general views of policy, minute details carefully elaborated, keen insight into men's characters, cunning directions when to dissimulate or when to be frank. From first to last the diplomatist peeps forth, and gives the key to his character, and to the causes of his success. Italian though he was by birth, education, and nature, France owed him a great debt for his skilful management during the early years of Louis XIV., and the king owed him yet more, for he had not only transmitted to him a nation at peace, but had educated for him his great servants Le Tellier, Lionne, and Colbert. Literary men owed him also much; not only did he throw his famous library open to them, but he pensioned all their leaders, including Descartes, Voiture, Balzac, and Pierre Corneille. The last-named, the greatest of them all, did not care for Mazarin as a paymaster only, but as a statesman; he was a profound royalist, believing that absolutism alone could save France from the horrors of religious wars, or the selfish turbulence of a Fronde, and to Mazarin he applied, with an adroit allusion to his birthplace, in the dedication of his *Pompée*, the line of Virgil—

"Tu regere imperio populos, Romane, memento."

All the earlier works on Mazarin, and early accounts of his administration, of which the best were Bazin's *Histoire de France sous Louis XIII. et sous le Cardinal Mazarin*, 4 vols., 1846, and Saint-Aulaire's *Histoire de la Fronde*, have been superseded by M. Cheruel's admirable *Histoire de France pendant la minorité de Louis XIV.*, 4 vols., 1879–80, which covers from 1643–51, and its sequel *Histoire de France sous le Ministère de Cardinal Mazarin*, 2 vols., 1881–82, which is the first account of the period written by one able to sift the statements of De Retz and the memoir writers, and rest upon such documents as Mazarin's letters and *carnets*. To M. Cheruel the Government of France has entrusted the task of editing Mazarin's *Letters*, of which two volumes have at present appeared, which must be carefully studied by any student of the history of France. For his "*carnets*" reference must be made to M. Cousin's articles in the *Journal des Savants*; for his early life to Cousin's *Jeunesse de Mazarin*, 1865, and for the careers of his nieces to Renée's *Les Nièces de Mazarin*, 1856. For the Mazarinades or squibs written against him in Paris during the Fronde, see Moreau's *Bibliographie des Mazarinades*, 1850, containing an account of 4082 Mazarinades. On the Fronde, also, consult Gaillardin's *Histoire de Louis XIV.*, 6 vols., 1876–78, and Feillet's interesting *Misère au temps de la Fronde*. For his foreign policy, besides his *Letters*, see Valfrey's *Hugues de Lionne*, and Mignet's *Histoire des Négociations relatives à la Succession d'Espagne*. (H. M. S.)

MAZATLAN, a city and seaport of Mexico, in the state of Cinaloa, on the coast of the Pacific, near the mouth of the Gulf of California, in 23° 18′ N. lat. and 106° 56′ W. long. It occupies an attractive situation, but, as the houses are for the most part low, has not an imposing appearance. The port is often visited by English and American vessels, and is consequently the seat of several consular agents. A large smuggling trade was formerly carried on in much the same lines as the present legitimate traffic—export of bullion, dye-stuffs, and pearls, and import of manufactured goods from Europe and fruits and vegetables from San Francisco. In 1878 the value of the imports was about £600,000, that of the exports about £500,000. The population, which contains a large floating element, was stated at 12,706 in 1871.

MAZEPPA, Ivan Stephanovitch (1644–1709), a Cossack chief, best known as the hero of one of Lord Byron's poems, was born in 1644, of a poor but noble

family, at Mazepintzui in the palatinate of Podolia. At an early age he became a page at the court of John Casimir, king of Poland. After some time he returned to his native province; but, engaging in an intrigue with a Polish matron of high rank, he was detected by the injured husband, and was sentenced to be bound naked on the back of an untamed horse. The animal on being let loose galloped off to its native wilds of the Ukraine. Mazeppa, half-dead and insensible, was released from his fearful position, and restored to animation by some poor peasants. In a short time his agility, courage, and sagacity rendered him popular among the Cossacks. He was appointed secretary and adjutant to Samoilovitch, their hetman or chief, and succeeded that functionary in 1687. The title of prince was afterwards conferred upon him by his friend and patron, Peter the Great, who long believed confidingly in his good faith, and banished or executed as calumnious traitors all who, like Palei, Kotchubey, and Iskra, ventured to accuse him of conspiring with the enemies of Russia. Bent, however, upon casting off the Russian yoke, Mazeppa became, in his seventieth year, and after much hesitation and inconstancy of purpose, an ally of the Swedish monarch, Charles XII. After the disastrous battle of Pultowa, fought, it is said, by his advice, Baturin, his capital, was taken and sacked by Menshikoff, and his name anathematized throughout the churches of Russia, and his effigy suspended from the gallows. A wretched fugitive, he escaped to Bender, but only to end his life by poison in 1709. Pushkin made Mazeppa the hero of his drama "Pultowa."

MAZZARA DEL VALLO, a city of Italy, on the coast of Sicily, in the province Trapani, 13 miles by rail south-east of Marsala. It is surrounded by a wall 37 feet in height, strengthened by towers rising at intervals; and it possesses a castle and a cathedral, both founded by Count Roger in the 11th century. The harbour is spacious but badly sheltered from the south winds. The population of the city was 11,756 in 1871; that of the commune was 10,999 in 1861 and 13,505 in 1881.

Mazara or Mazaris appears from Diodorus Siculus (xiii. 54) to have been a trading establishment of Selinus, and it was captured by the Carthaginian general in 409 B.C. on his march against that city. It was in this neighbourhood that the Saracens landed in 827 A.D.; and the name of Val di Mazzara long indicated one of the three divisions of Sicily.

MAZZINI, Giuseppe (1805–1872), Italian patriot, was born on June 22, 1805, at Genoa, where his father, Giacomo Mazzini, was a physician in good practice, and a professor in the university. His mother is described as having been a woman of great personal beauty, as well as of active intellect and strong affections. During infancy and childhood his health was extremely delicate, and it appears that he was nearly six years of age before he was quite able to walk; long before this, however, he had learned to read, and otherwise begun to show great intellectual precocity. His first tutor was an old priest who taught him Latin, but his omnivorous reading was not directed by any master. At the age of thirteen he began to attend classes in the faculty of arts at the university; he afterwards studied anatomy with a view to following his father's profession, but finally (1826) graduated in laws. Apart from his professional studies, he took lessons in music, English, and fencing. Of his student days little more is recorded than that his exceptional abilities as well as the remarkable generosity and benevolence of his impulses and aims were quickly recognized by his comrades,—his professors, however, having frequent occasion to complain of his disregard for conventional rules. As to his inner life during this period, we have only one brief but significant sentence; "for a short time," he says, "my mind was somewhat tainted by the doctrines of the foreign materialistic school; but the study of history and the intuitions of conscience—the only tests of truth—soon led me back to the spiritualism of our Italian fathers." For some time after his admission as an advocate Mazzini was occupied in the Ufficio dei Poveri; but, although he seems to have discharged the duties arising from this with zeal and success, he never really overcame his repugnance to the dry and technical details of legal practice. The natural bent of his genius was towards literature, and, in the course of the four years of his nominal connexion with the legal profession, he wrote a considerable number of essays and reviews, some of which have been wholly or partially reproduced in the critical and literary volumes of his *Life and Writings*. His first essay, characteristically enough on "Dante's Love of Country," was sent to the editor of the *Antologia Fiorentina* in 1826, but did not appear until some years afterwards in the *Subalpino*. He was an ardent supporter of romanticism as against what he called "literary servitude under the name of classicism"; and in this interest all his critiques (as, for example, that of Giannoni's *Exile* in the *Indicatore Livornese*, 1829) were penned. But in the meantime the "republican instincts" which he tells us he had inherited from his mother had been developing, and his sense of the evils under which Italy was groaning had been intensified; and at the same time he became possessed with the idea that Italians, and he himself in particular, "*could* and therefore *ought* to struggle for liberty of country." His literary articles accordingly became more and more suggestive of advanced liberalism in politics, and led to the suppression by Government of the *Indicatore Genovese* and the *Indicatore Livornese* successively. Having joined the Carbonari, he soon rose to one of the higher grades in their hierarchy, and was entrusted with a special secret mission into Tuscany; but, as his acquaintance grew, his dissatisfaction with the organization of the society increased, and he was already meditating the formation of a new association having closer bonds of union and more definite aims when shortly after the French revolution of 1830 he was betrayed, while initiating a new member, to the authorities of Piedmont. He was imprisoned in the fortress of Savona on the western Riviera for about six months, when, a conviction having been found impracticable through deficiency of evidence, he was released, but upon conditions involving so many restrictions of his liberty that he preferred the alternative of leaving the country. He withdrew accordingly into France, living chiefly in Marseilles. While in his lonely cell at Savona, in presence of "those symbols of the infinite, the sky and the sea," with a greenfinch for his sole companion, and having access to no books but "a Tacitus, a Byron, and a Bible," he had finally become aware of the great mission or "apostolate" (as he himself called it) of his life; and soon after his release his prison meditations took shape in the programme of the organization which was destined soon to become so famous throughout Europe, that of *La Giovine Italia*, or Young Italy. Its publicly avowed aims were to be the liberation of Italy both from foreign and domestic tyranny, and its unification under a republican form of government; the means to be used were education, and, where advisable, insurrection by guerrilla bands; the motto was to be "God and the people," and the banner was to bear on one side the words "Unity" and "Independence" and on the other "Liberty," "Equality," and "Humanity," to describe respectively the national and the international aims. In April 1831 Charles Albert, "the ex-Carbonaro conspirator of 1821," succeeded Charles Felix on the Sardinian throne, and towards the close of that year Mazzini, making himself, as he afterwards confessed, "the interpreter of a hope which he did not share," wrote the new king a letter, published at Marseilles, urging him to take the lead in the impending

struggle for Italian independence. Clandestinely reprinted, and rapidly circulated all over Italy, its bold and outspoken words produced a great sensation, but so deep was the offence it gave to the Sardinian Government that orders were issued for the immediate arrest and imprisonment of the author should he attempt to cross the frontier. Towards the end of the same year appeared the important Young Italy "Manifesto," the substance of which is given in the first volume of the *Life and Writings* of Mazzini; and this was followed soon afterwards by the society's *Journal*, which, smuggled across the Italian frontier, had great success in the objects for which it was written, numerous "congregations" being formed at Genoa, Leghorn, and elsewhere. Representations were consequently made by the Sardinian to the French Government, which issued in an order for Mazzini's withdrawal from Marseilles (August 1832); he lingered for a few months in concealment, but ultimately found it necessary to retire into Switzerland. From this point it is somewhat difficult to follow the career of the mysterious and terrible conspirator who for twenty years out of the next thirty led a life of voluntary imprisonment (as he himself tells us) "within the four walls of a room," and "kept no record of dates, made no biographical notes, and preserved no copies of letters." In 1833, however, he is known to have been concerned in an abortive revolutionary movement which took place in the Sardinian army; several executions took place, and he himself was laid under sentence of death. Before the close of the same year a similar movement in Genoa had been planned, but failed through the youth and inexperience of the leaders. At Geneva, also in 1833, Mazzini set on foot *L'Europe Centrale*, a journal of which one of the main objects was the emancipation of Savoy; but he did not confine himself to a merely literary agitation for this end. Chiefly through his agency a considerable body of German, Polish, and Italian exiles was organized, and an armed invasion of the duchy planned. The frontier was actually crossed on February 1, 1834, but the attack ignominiously broke down without a shot having been fired. Mazzini, who personally accompanied the expedition, is no doubt correct in attributing the failure to dissensions with the Carbonari leaders in Paris, and to want of a cordial understanding between himself and the Savoyard Ramorino, who had been chosen as military leader. In April 1834 the "Young Europe" association "of men believing in a future of liberty, equality, and fraternity for all mankind, and desirous of consecrating their thoughts and actions to the realization of that future" was formed, also under the influence of Mazzini's enthusiasm; it was followed soon afterwards by a "Young Switzerland" society, having for its leading idea the formation of an Alpine confederation, to include Switzerland, Tyrol, Savoy, and the rest of the Alpine chain as well. But *La Jeune Suisse* newspaper was compelled to stop within a year, and in other respects the affairs of the struggling patriot became embarrassed. He was permitted to remain at Grenchen in Solothurn for a while, but at last the Swiss diet, yielding to strong and persistent pressure from abroad, exiled him about the end of 1836. In January 1837 he arrived in London, where for many months he had to carry on a hard fight with poverty and the sense of spiritual loneliness so touchingly described by himself in the first volume of the *Life and Writings*. Ultimately, as he gained command of the English language, he began to earn a livelihood by writing review articles, some of which have since been reprinted, and are of a high order of literary merit; they include papers on "Italian Literature since 1830" and "Paolo Sarpi" in the *Westminster Review*, articles on "Lamennais," "George Sand," "Byron and Goethe" in the *Monthly Chronicle*, and on "Lamartine," "Carlyle," and "The Minor Works of Dante" in the *British and Foreign Review*. In 1839 he entered into relations with the revolutionary committees sitting in Malta and Paris, and in 1840 he originated a working men's association, and the weekly journal entitled *Apostolato Popolare*, in which the admirable popular treatise "On the Duties of Man" was commenced. Among the patriotic and philanthropic labours undertaken by Mazzini during this period of retirement in London may be mentioned a free evening school conducted by himself and a few others for some years, at which several hundreds of Italian children received at least the rudiments of secular and religious education. The most memorable episode in his life during the same period was perhaps that which arose out of the conduct of Sir James Graham, the home secretary, in systematically, for some months, opening Mazzini's letters as they passed through the British post-office, and communicating their contents to the Neapolitan Government—a proceeding which brought about the arrest and execution of the brothers Bandiera, Austrian subjects, who had been planning an expedition against Naples. The prolonged discussions in parliament, and the report of the committee appointed to inquire into the matter, did not, however, lead to any practical result, unless indeed the incidental vindication of Mazzini's character, which had been recklessly assailed in the course of debate. Mazzini did not share the enthusiastic hopes everywhere raised in the ranks of the Liberal party throughout Europe by the first acts of Pius IX., in 1846, but at the same time he availed himself, towards the end of 1847, of the opportunity to publish a letter addressed to the new pope, indicating the nature of the religious and national mission which the Liberals expected him to undertake. The leaders of the revolutionary outbreaks in Milan and Messina in the beginning of 1848 had long been in secret correspondence with Mazzini; and their action, along with the revolution in Paris, brought him early in the same year to Italy, where he took a great and active interest in the events which dragged Charles Albert into an unprofitable war with Austria; he actually for a short time bore arms under Garibaldi immediately before the re-occupation of Milan, but ultimately, after vain attempts to maintain the insurrection in the mountain districts, found it necessary to retire to Lugano. In the beginning of the following year he was nominated a member of the short-lived provisional government of Tuscany formed after the flight of the grand-duke, and almost simultaneously, when Rome had, in consequence of the withdrawal of Pius IX., been proclaimed a republic, he was declared a member of the constituent assembly there. A month afterwards, the battle of Novara having again decided against Charles Albert in the brief struggle with Austria, into which he had once more been drawn, Mazzini was appointed a member of the triumvirate, with supreme executive power. The opportunity he now had for showing the administrative and political ability which he was believed to possess was more apparent than real, for the approach of the professedly friendly French troops soon led to hostilities, and resulted in a siege which terminated, towards the end of June, with the assembly's resolution to discontinue the defence, and Mazzini's indignant resignation. That he succeeded, however, for so long a time, and in circumstances so adverse, in maintaining a high degree of order within the turbulent city is a fact that speaks for itself. His diplomacy, backed as it was by no adequate physical force, naturally showed at the time to very great disadvantage, but his official correspondence and proclamations can still be read with admiration and intellectual pleasure, as well as his eloquent vindication of the revolution in his published "Letter to MM. de Tocqueville and De Falloux."

The surrender of the city on June 30 was followed by Mazzini's not too precipitate flight by way of Marseilles into Switzerland, whence he once more found his way to London. Here in 1850 he became president of the National Italian Committee, and at the same time entered into close relations with Ledru-Rollin and Kossuth. He had a hand in the abortive rising at Mantua in 1852, and again, in February 1853, a considerable share in the formidable insurrection which broke out at Milan; once more, in 1854, he had gone far with preparations for renewed action when his plans were completely disconcerted by the withdrawal of professed supporters, and by the action of the French and English Governments in sending ships of war to Naples. The year 1857 found him yet once more in Italy, where, for complicity in short-lived emeutes which took place at Genoa, Leghorn, and Naples, he was again laid under sentence of death. Undiscouraged in the pursuit of the one great aim of his life by any such incidents as these, he returned to London, where he edited his new journal *Pensiere ed Azione*, in which the constant burden of his message to the overcautious practical politicians of Italy was—"I am but a voice crying *Action*; but the state of Italy cries for it also. So do the best men and people of her cities. Do you wish to destroy my influence? *Act*." The same tone was at a somewhat later date assumed in the letter he wrote to Victor Emmanuel, urging him to put himself at the head of the movement for Italian unity, and promising republican support. As regards the events of 1859–60, however, it may be questioned whether, through his characteristic inability to distinguish between the ideally perfect and the practically possible, he did not actually hinder more than he helped the course of events by which the realization of so much of the great dream of his life was at last brought about. As has been said elsewhere (vol. xiii. p. 487), if Mazzini was the prophet of Italian unity, and Garibaldi its knight errant, to Cavour alone belongs the honour of having been the statesman by whom it was finally accomplished. After the irresistible pressure of the popular movement had led to the establishment not of an Italian republic but of an Italian kingdom, Mazzini could honestly enough write, "I too have striven to realize unity under a monarchical flag," but candour compelled him to add, "The Italian people are led astray by a delusion at the present day, a delusion which has induced them to substitute material for moral unity and their own reorganization. Not so I. I bow my head sorrowfully to the sovereignty of the national will; but monarchy will never number me amongst its servants or followers." In 1865, by way of protest against the still uncancelled sentence of death under which he lay, Mazzini was elected by Messina as delegate to the Italian parliament, but, feeling himself unable to take the oath of allegiance to the monarchy, he never took his seat. In the following year, when a general amnesty was granted after the cession of Venice to Italy, the sentence of death was at last removed, but he declined to accept such an "offer of oblivion and pardon for having loved Italy above all earthly things." In May 1869 he was again expelled from Switzerland at the instance of the Italian Government for having conspired with Garibaldi; after a few months spent in England he set out (1870) for Sicily, but was promptly arrested at sea and carried to Gaeta, where he was imprisoned for two months. Events soon made it evident that there was little danger to fear from the contemplated rising, and the occasion of the birth of a prince was seized for restoring him to liberty. The remainder of his life, spent partly in London and partly at Lugano, presents no noteworthy incidents. For some time his health had been far from satisfactory, but the immediate cause of his death was an attack of pleurisy with which he was seized at Pisa, and which terminated fatally on March 10, 1872. The Italian parliament by a unanimous vote expressed the national sorrow with which the tidings of his death had been received, the president pronouncing an eloquent eulogy on the departed patriot as a model of disinterestedness and self-denial, and one who had dedicated his whole life ungrudgingly to the cause of his country's freedom. A public funeral took place at Pisa on March 14, and the remains were afterwards conveyed to Genoa.

The published writings of Mazzini, mostly occasional, are very voluminous, and have nowhere been exhaustively collected. The fullest edition of them is that begun by himself and continued by Satti (*Scritti editi e inediti di Giuseppe Mazzini*, 10 vols., 1861–80); many of the most important are found in the partially autobiographical work already referred to (*Life and Writings of Joseph Mazzini*, 6 vols., 1864–70), and the two most systematic—"Thoughts upon Democracy in Europe," a remarkable series of criticisms on Benthamism, St-Simonianism, Fourierism, and other economic and socialistic schools of the day, and the treatise "On the Duties of Man," an admirable primer of ethics, dedicated to the Italian working class—will be found in a volume entitled *Joseph Mazzini, a Memoir*, by Mrs E. A. Venturi (London, 1875). Mazzini's "first great sacrifice," he tells us, was "the renunciation of the career of literature for the more direct path of political action," and as late as 1861 we find him still recurring to the long-cherished hope of being able to leave the stormy arena of politics and consecrate the last years of his life to the dream of his youth. He had specially contemplated three considerable literary undertakings,—a volume of *Thoughts on Religion*, a popular *History of Italy*, to enable the working classes to apprehend what he conceived to be the "mission" of Italy in God's providential ordering of the world, and a comprehensive collection of translations of ancient and modern classics into Italian. None of these was actually achieved. No one, however, can read even the briefest and most occasional writing of Mazzini without gaining some impression of the simple grandeur of the man, the lofty elevation of his moral tone, his unwavering faith in the living God, who is ever revealing Himself in the progressive development of humanity. His last public utterance is to be found in a highly characteristic article on Renan's *Réforme Morale et Intellectuelle*, finished on March 3, 1872, and published in the *Fortnightly Review* for February 1874. (J. S. BL.)

MAZZOLA. See PARMIGIANO.

MEAD, RICHARD (1673–1754), physician, was born on August 11, 1673, at Stepney (near London), where his father, at one time minister of the parish, had been ejected for nonconformity in 1662. He was sent to Utrecht, where he studied for three years under Grævius; having decided to follow the medical profession, he then went to Leyden and attended the lectures of Hermann and Pitcairn. In 1695 he graduated in philosophy and physic at Padua, and in the following year he returned to his native place, entering at once on a successful practice. His *Mechanical Account of Poisons* appeared in 1702, and in 1703 he was admitted to the Royal Society, to whose *Transactions* he contributed in that year a paper on the parasitic nature of scabies. In the same year he was also elected physician to St Thomas's Hospital, and appointed to read anatomical lectures at the Surgeons' Hall. On the death of Radcliffe in 1714 Mead became the recognized head of his profession; he attended Queen Anne on her death-bed, and in 1727 was appointed physician to George II., having previously served him in that capacity when he was prince of Wales. He died on February 16, 1754. For his place in the annals of medical science see MEDICINE, p. 811 of the present volume.

Besides the *Mechanical Account of Poisons*, of which a second edition appeared in 1708, Mead published a treatise *De Imperio Solis et Lunæ in Corpora Humana et Morbis inde Oriundis* (1704), *A Short Discourse concerning Pestilential Contagion, and the Method to be used to prevent it* (1720), *De Variolis et Morbillis Dissertatio* (1747), *Medica Sacra, sive de Morbis insignioribus qui in Bibliis memorantur Commentarius* (1748), *On the Scurvy* (1749), and *Monita et Præcepta Medica* (1751). A *Life* of Mead by Dr Maty appeared in 1755.

MEADVILLE, a city of the United States, county seat of Crawford county, Pennsylvania, on the left bank of French Creek, a tributary of the Alleghany river, and at

tne junction of the Franklin branch with tne main line of the New York, Pennsylvania, and Ohio Railroad, 102 miles from Salamanca. It is a well-built town, maintains a large trade with the oil regions, and has railway and other machine works, glass works, woollen mills, and paper mills. The Meadville theological school was established by the Unitarians in 1844; and Allegheny College, opened in 1816 as a Presbyterian Church institution, has been carried on since 1833 by the Methodist Episcopal Church. Meadville was founded by General David Mead as a fortified post in 1789. In 1816 it had only 400 inhabitants; but the number was 3702 in 1860, 7103 in 1870, and 8860 in 1880.

MEASLES (*Morbilli*, *Rubeola*; German, *Masern*; French, *Rougeole*), an acute infectious disease occurring mostly in children. It appears to have been known from an early period in the history of medicine, mention being made of it in the writings of Rhazes and others of the Arabian physicians in the 10th century. For long, however, its specific nature was not recognized, and it was held to be a variety of small-pox. After the non-identity of these two diseases had been established, measles and scarlet fever continued to be confounded with each other; and in the account given by Sydenham of epidemics of measles in London in 1670 and 1674 it is evident that even that accurate observer had not as yet clearly perceived their pathological distinction, although it would seem to have been made a century earlier by Ingrassias, a physician of Palermo. It is only within a comparatively recent period that measles has come to be universally regarded as a distinct and independent malady.

Like the other eruptive fevers (exanthemata), to which class of diseases measles belongs, its progress is marked by several stages more or less sharply defined.

After the reception of the contagion into the system a period of incubation or latency precedes the development of the disease, during which scarcely any disturbance of the health is perceptible. This period appears to vary in duration, but it may be stated as generally lasting for from ten to fourteen days, when it is followed by the invasion of the symptoms specially characteristic of measles. These consist in the somewhat sudden onset of acute catarrh of the mucous membranes. Sneezing, accompanied with a watery discharge, sometimes bleeding, from the nose, redness and watering of the eyes, cough of a short, frequent, and noisy character, with little or no expectoration, hoarseness of the voice, and occasionally sickness and diarrhœa, are the chief local phenomena of this stage. But along with these there is well-marked febrile disturbance, the temperature being elevated (102°–104° F.), and the pulse rapid, while headache, thirst, and restlessness are usually present to a greater or less degree. In some instances, however, these initial symptoms are so slight that they almost escape notice, and the child is allowed to associate with others at a time when, as will be afterwards seen, the contagion of the disease is most active. In rare cases, especially in young children, convulsions usher in, or occur in the course of, this stage of invasion, which lasts as a rule for four or five days, the febrile symptoms, however, showing some tendency to undergo abatement after the second day. On the fourth or fifth day after the invasion, sometimes later, rarely earlier, the characteristic eruption appears on the skin, being first noticed on the brow, cheeks, chin, also behind the ears, and on the neck. It consists of small spots of a dusky red or crimson colour, slightly elevated above the surface, at first isolated, but tending to become grouped together into patches of irregular, occasionally crescentic, outline, with portions of skin free from the eruption intervening. The face acquires a swollen and bloated appearance, which, taken along with the catarrh of the nostrils and eyes, is almost characteristic, and renders the diagnosis at this stage a matter of no difficulty. The eruption spreads downwards over the body and limbs, which are soon thickly studded with the red spots or patches. Sometimes these become confluent over a considerable surface, giving rise to a larger area of uniform redness. The rash continues to come out for two or three days, and then begins to fade in the order in which it first showed itself, namely, from above downwards. By the end of about a week after its first appearance scarcely any trace of the eruption remains beyond a faint staining of the skin. Occasionally during convalescence slight peeling of the epidermis takes place, but much less frequently and distinctly than is the case in scarlet fever. At the commencement of the eruptive stage the fever, catarrh, and other constitutional disturbance, which were present from the beginning, become aggravated, the temperature often rising to 105° or more, and there is headache, thirst, furred tongue, and soreness of the throat, upon which red patches similar to those on the surface of the body may be observed. These symptoms usually decline as soon as the rash has attained its maximum, and often there occurs a sudden and extensive fall of temperature, indicating that the crisis of the disease has been reached. In favourable cases convalescence proceeds rapidly, the patient feeling perfectly well even before the rash has faded from the skin.

Measles may, however, occur in a very severe or malignant form, in which the symptoms throughout are of urgent character, the rash but feebly developed, and of dark purple hue, while there is great prostration of strength, accompanied with intense catarrh of the respiratory or gastro-intestinal mucous membrane. Such cases, always of serious import, are happily rare, occurring mostly in circumstances of bad hygiene, both as regards the individual and his surroundings. On the other hand, cases of measles are often met with of so mild a form throughout that the patient can scarcely be persuaded to submit to treatment.

Measles as a disease derives its chief importance in the view of medical men from the risk, by no means slight, of certain complications which are apt to arise during its course, more especially inflammatory affections of the respiratory organs. These are most liable to occur in the colder seasons of the year and in very young and delicate children. It has been already stated that irritation of the respiratory passages is one of the symptoms characteristic of measles, but that this subsides with the decline of the eruption. Not unfrequently, however, these symptoms, instead of abating, become aggravated, and bronchitis of the capillary form (see BRONCHITIS), or pneumonia, generally of the diffuse or lobular variety (see PNEUMONIA), impart a gravity to the case which it did not originally possess. By far the greater proportion of the mortality in measles is due to its complications, of which those just mentioned are the most common, but which also include inflammatory affections of the larynx, with attacks resembling croup, and also diarrhœa assuming a dysenteric character. Or there may remain as direct results of the disease chronic ophthalmia, or discharge from the ears, with deafness, and occasionally a form of gangrene affecting the tissues of the mouth or cheeks and other parts of the body, leading to disfigurement and even endangering life.

Apart, however, from those immediate risks, it deserves to be borne in mind that in measles there appears to be a tendency in many cases for the disease to leave behind a weakened and vulnerable condition of the general health, which may render children, previously robust, delicate and liable to chest complaints, and is in not a few instances the precursor of some of those tubercular affections to which the period of childhood and youth is liable.

These various effects or sequelæ of measles plainly indicate that although in itself a comparatively mild

ailment, it cannot safely be regarded with indifference. Indeed it is doubtful whether any other disease of early life demands more careful watching as to its influence on the health. Happily many of those attending evils now alluded to may by proper management be averted.

Measles is a disease of the earlier years of childhood. Like other infectious maladies, it is admittedly rare, though not unknown, in nurslings or infants under six months old. It is comparatively seldom met with in adults, but this is simply due to the fact that most persons have undergone an attack in early life, since, where this has not been the case, the old suffer equally with the young. All races of men appear liable to this disease, provided that which constitutes the essential factor in its origin and spread exists, namely, contagion. Some countries enjoy long immunity from outbreaks of measles, but it has frequently been found in such cases that when the contagion has once been introduced the disease extends with great rapidity and virulence. This was shown in two well-known instances in recent times,—namely, the epidemic in the Faroe Islands in 1846, where, within six months after the arrival of a single case of measles, more than three-fourths of the entire population were attacked and many perished; and the similarly produced and still more destructive outbreak in Fiji in 1875, in which it was estimated that about one-fourth of the inhabitants were cut off by the disease within a period of about three months (see FIJI). In both these cases the great mortality has been ascribed to the complications of the malady, specially induced by over-crowding, by insanitary surroundings, the absence of proper nourishment and nursing for the sick, and the utter prostration and terror of the people, rather than to any marked malignancy in the type of the disease.[1] Not a few authorities, however, while fully recognizing the baneful effect of these unfavourable conditions, are yet disposed to hold that epidemics of this kind, when occurring in what might be termed a virgin soil, are apt to possess an innate severity. In many lands, such as the United Kingdom, measles is rarely absent, especially from large centres of population, where sporadic cases are found in greater or less number at all seasons. Every now and then epidemics arise from the extension of the disease among those members of a community who have not been in some measure protected by a previous attack. There are few diseases so contagious as measles, and its rapid spread in epidemic outbreaks is no doubt due to the well-ascertained fact that contagion is most potent in the earlier stages, even before its real nature has been evinced by the characteristic appearances on the skin. Hence the difficulty of timely isolation, and the readiness with which the disease is spread in schools and families. There is little doubt too that the contagion may be carried from one place to another by persons themselves unaffected, as well as by clothing, &c., although its tenacity and activity in this respect is apparently much less marked than that of small-pox or scarlet fever. Of the nature of the infecting agent nothing certain is known. Recent investigations into the mode of origin of others of the acute infectious diseases, and the discovery in the blood and tissues in the case of some of them of lower forms of organic life (bacilli), which can be isolated and can by inoculation be made to communicate the particular malady to which they are related, give countenance to the opinion, now widely entertained, that the infecting principle of the exanthemata is of this nature. The subject, however, is still under investigation, and more information is wanting before definite statements can be made. Second attacks of measles are occasionally observed, but they are rare.

[1] *Transactions of the Epidemiological Society.* London, 1877.

*Treatment.*—The treatment of measles embraces the preventive measures to be adopted in the case of an outbreak by the isolation of the sick at as early a period as possible. Epidemics have often, especially in limited localities, been curtailed by such a precaution. In families with little house accommodation this measure is frequently, for the reason already referred to regarding the communicable period of the disease, ineffectual; nevertheless where practicable it ought to be tried, for it is a grave error needlessly to expose the healthy children in a family to the risk of infection under the idea that they must necessarily take the disease at some time or other. The unaffected children should likewise be kept from school for a time (probably about three weeks from the outbreak in the family would suffice if no other case occur in the interval), and all clothing in contact with the patient should be subjected to disinfection or thorough washing. In extensive epidemics it is often desirable to close the schools of a locality for a time. As regards special treatment, in an ordinary case of measles little is required beyond what is necessary in febrile conditions generally. Confinement to bed in a somewhat darkened room, into which, however, air is freely admitted in such a manner as to avoid the risk of draughts, light nourishing liquid diet (soups, milk, &c.), and mild diaphoretic remedies such as the acetate of ammonia or ipecacuanha, are all that is necessary in the febrile stage. When the catarrhal symptoms are very severe, the hot bath or warm packing to the body generally or to the chest and throat afford relief, and the same measures may with advantage be adopted should the eruption be but feebly developed or tend to recede, and especially should convulsions set in. The serious chest complications of measles are to be dealt with by those measures applicable for the relief of the particular symptoms (see BRONCHITIS, PNEUMONIA). The inhalation of vapour and the use of the preparations of ammonia are of special efficacy. Diarrhœa is treated by the usual remedies, including carefully administered doses of Dover's powder, chalk, &c. During convalescence the patient must be guarded from exposure to cold, and for a time after recovery the state of the health ought to be watched with the view of averting the evils, both local and constitutional, which but too often follow this disease.

*German Measles* (*Rötheln*, or *Epidemic Roseola*) is a term applied to a contagious eruptive disorder having certain points of resemblance to measles, and, according to some observers, also to scarlet fever, but exhibiting its distinct individuality in the fact that it protects from neither of these diseases. It occurs most commonly in children, and is occasionally seen in extensive epidemics. Beyond confinement to the house in the eruptive stage, which, from the slight symptoms experienced, is often difficult of accomplishment, no special treatment is called for. There is little doubt that the disease is often mistaken for true measles, and many of the alleged second attacks of the latter malady are probably cases of rötheln. The chief points of difference are the following:—

1. The absence of distinct premonitory symptoms, the stage of invasion, which in measles is usually of four days' duration, and accompanied with well-marked fever and catarrh, being in rötheln either wholly absent or exceedingly slight, enduring only for one day.

2. The eruption of rötheln, which, although as regards its locality and manner of progress similar to measles, differs somewhat in its appearance, the spots being of smaller size, paler colour, and with less tendency to grouping in crescentic patches. The rash attains its maximum in about one day, and quickly disappears. There is no accompanying increase of temperature in this stage as in measles.

3. The milder character of the symptoms of rötheln throughout its whole course, and the absence of complications and of liability to subsequent impairment of health such as have been seen to appertain to measles. (J. O. A.)

MEASUREMENT. We propose in the first place to enter into some detail on the fundamental principles of the theory of measurement, and in doing so it will be necessary to sketch the very remarkable theory established by Riemann and other mathematicians as to the foundations of our geometrical knowledge.

Every system of geometrical measurement, as indeed the whole science of geometry itself, is founded on the possibility of transferring a fixed figure from one part of space to another with unchanged form. We are so familiar with this process that we are apt not to realize its importance until very special attention has been directed to the subject. We therefore propose to make a logical examination of the nature of the assumptions involved in the possibility of moving a figure in space so that it shall undergo no alteration. We shall find that we require to postulate certain suppositions with regard to the nature of space and to the measurement of distances.

It will facilitate the conception of this somewhat difficult subject to consider the case of hypothetical reasoning beings which Sylvester described as being infinitely attenuated bookworms confined to infinitely thin sheets of paper. We suppose such two-dimensional beings to be absolutely limited to a certain surface. They could have no conception of space except as of two dimensions. The movement of a point would for them form a line, the movement of a line would form a surface. They could conduct their measurements and form their geometrical theories. They would be able to draw the shortest lines between two points, these lines being what we would call geodesics. To these two-dimensioned geometers geodesics would possess many of the attributes of straight lines in ordinary space. If the surface to which the beings were confined were actually a plane, then the geometry would be the same as our geometry. They would find that only one straight line could be drawn between two points, that through a point only one parallel to a given line could be drawn, and that the ends of a line would never meet even though the line be prolonged to infinity.

We might also suppose that intelligent beings could exist on the surface of a sphere. Their straightest line between two points would be the arc of the great circle joining those two points. They would also find that a second geodesic could be drawn joining the two points, this being of course the remaining part of the great circle. A curious exception would, however, be presented by two points diametrically opposite. An infinite number of geodesics can be drawn between these points and all those geodesics are of equal length. The axiom that there is one shortest line between two given points would thus not hold without exception. There would be no parallel lines known to the dwellers on the sphere. It would be found by them that every two geodesics must intersect, not only in one, but even in two points. The sum of the three angles of a triangle would for them not be constant. It would always be greater than two right angles, and would increase with the area of the triangle. They would thus have no conception of similarity between two geometrical figures of different sizes. If two triangles be constructed which have their sides proportional, the angles of the larger triangle would be greater than the corresponding angles of the smaller triangle.

It is thus plain that the geometrical axioms of the sphere-dwellers must be very different from those of the plane-dwellers. The different axioms depend upon the different kinds of space which they respectively inhabit, while their logical powers are identical. In one sense, however, the dwellers on the sphere and on the plane have an axiom in common. In each case it will be *possible for a figure to be moved about without alteration of its dimensions.* A spherical triangle can be moved on the surface of a sphere without distortion just as a plane triangle may be moved in a plane. The sphere-dwellers and the plane-dwellers would be equally able to apply the test of congruence. It is, however, possible to suppose reasoning beings confined to a space in which the translation of a rigid figure is impossible. Take, for instance, the surface of an ellipsoid or even a spheroid such as the surface of the earth itself. A triangle drawn on the earth at the equator could not be transferred to the surface of the earth near the pole and still preserve all its sides and all its angles intact.

If a surface admits of a figure being moved about thereon so as still to retain all its sides and all its angles unaltered, then that surface must possess certain special properties. It can be shown that, if a surface is to possess this property, a certain function known as the "measure of curvature" is to be constant. The measure of curvature is the reciprocal of the product of the greatest and least radii of curvature. We do not now enter into the proof, but it is sufficiently obvious that a sphere of which the radius is the geometric mean between the greatest and least radii of curvature at each point will to a large extent osculate the surface, so that a portion of the surface in the neighbourhood of the point will, generally speaking, have the same curvature as the sphere. If the sphere thus determined be the same at all the different points of the surface, then the curvature of the different parts of the surface will on the whole resemble that of the sphere, and therefore we cannot be surprised that the surface possessing this property will admit the displacement of a rigid figure thereon without derangement of its form.

We are thus conducted to a kind of surface the geometry of which is similar to that of the plane, but in which the axiom of parallels does not hold good. In this surface the radii of curvature at every point have opposite signs, so that the measure of curvature which is zero for the plane and positive for the sphere is negative for the surface now under consideration. This surface has been called the "pseudosphere," and its nature has been investigated by Beltrami.[1] In the geometry of two dimensions we can thus have either a plane or a sphere or a pseudosphere which are characterized by the property that a surface may be moved about in all directions without any change either in the lengths of its lines or in the magnitudes of its angles. The axiom which assumes that there is only one geodesic connecting two points marks off the plane and the pseudosphere from the sphere. The axiom that only one parallel can be drawn through a given point to a given line marks off the plane from the pseudosphere. The geometry of Euclid is thus specially characterized among all conceivable geometries of two dimensions by the following three axioms—(1) the mobility of rigid figures, (2) the single geodesic between two points, (3) the existence of parallels.

A very interesting account of this theory will be found in Clifford's *Lectures and Essays*, vol. i. p. 317. We shall follow to some extent the method employed by him in order to obtain an idea of the important conception which is called the "curvature of space." Suppose a geodesic be drawn on a surface of constant curvature. Then a piece of the surface adjoining this geodesic can be slid along the curve so as all the time to fit in close contact therewith. If the piece of surface be turned to the other side of the geodesic it will still fit along this side. A

[1] *Saggio di Interpretazione della Geometria non-Euclidea*, Naples, 1868; "Teoria fondamentale degli sparii di curvatura constante," *Annali di Matematica*, ser. ii. tom. ii. pp. 232–55. Both papers have been translated into French by J. Houël (*Annales Scientifiques de l'École Normale*, tom. v., 1869). An exceedingly interesting account of the whole subject will be found in Helmholtz, *Popular Lectures on Scientific Subjects*, translated by Atkinson, second series, London, 1881, pp. 27–71.

line possessing this property is called by Leibnitz a straight line. It can be easily shown that a geodesic drawn on a figure will also be a geodesic when the figure is transferred to any other position. Suppose that the figure be divided into two parts A and B by the geodesic; then the part B can be moved round so as to lie upon A, and the boundary lines of the two portions will be coincident. Now let the two parts while superposed be translated to any other position, then the piece B may be slid off and back to its original position with regard to A. It must still fit, because the whole figure might have been translated before the subdivision took place. It follows that the division between A and B having been a geodesic in its original position will continue to be a geodesic however the figure may be translated.

In a similar way we obtain the conception of a plane. According to Leibnitz's definition a plane is a surface such that if a portion of the space contiguous thereto be slid along the surface it will continuously fit, and if the portion of space be transferred to the other side of the surface it will fit also. This definition has no meaning except we assume that the bodies may be translated in space without derangement of their dimensions. From any point we can imagine a doubly infinite number of geodesics radiating in all directions; if a plane be drawn through the point, then all the geodesics touching the plane at that point form what may be called a "geodesic surface." It is shown that geodesic surfaces of this description can alone fulfil the conditions by which planes are to be defined. A doubly infinite number of geodesic surfaces can be drawn through every point. If a rigid body be divided into two parts by a geodesic plane, then no matter how the body be displaced the plane of section will still be geodesic. The plane of section may be made to pass through any point, and the body may then be given such an aspect as shall cause the section to coincide with any geodesic surface through the point, but this necessarily involves that the section shall fit each geodesic surface, in other words, that *all the geodesic surfaces shall have a constant curvature.*

The point which we have now gained is one of very great importance. In our ordinary conceptions of space the geodesic surfaces are of course our ordinary planes, and the common curvature they possess is zero, but the condition that rigid bodies shall be capable of translation with unaltered features does not require that the curvatures shall be zero, it merely requires that the curvatures shall be constant. If we add, however, the postulate of similarity, then the curvatures must be zero. The postulate of similarity requires that it shall be possible to construct a figure on any scale and anywhere similar to a given figure. This practically includes the ordinary doctrine of parallels. Lobatchewsky developed the system of geometry on the supposition that the space had a constant curvature different from zero. In this geometry the parallels can be drawn through a given point to a given line, and, to quote Clifford—

"The sum of the three angles of a triangle is less than two right angles by a quantity proportional to the area of the triangle. The whole of this geometry is worked out in the style of Euclid, and the most interesting conclusions are arrived at, particularly in the theory of solid space, in which a surface turns up which is not plane relatively to that space but which for the purpose of drawing figures upon it is identical with the Euclidean plane."

The most comprehensive mode of viewing the whole theory is that adopted by Riemann in his celebrated memoir "Ueber die Hypothesen welche der Geometrie zu Grunde liegen," 1854 (*Abhandl. der königl. Gesellsch. zu Göttingen*, vol. xiii.).[1] The analytical treatment of this subject possesses one obvious advantage. The use of symbols only admits of deductions on purely logical principles. There is not therefore the risk of tacitly introducing other axioms in addition to those with which we started.

Magnitudes which have only one dimension present the theory of measurement in its simplest form. The length of a straight line may be taken as an illustration of a one-dimensioned magnitude. The velocity of a moving particle, the temperature of a heated body, the electric resistance of a metal, all these and many others are instances of one-dimensioned magnitude, the measure of which is to be expressed by a single quantity. But there may be magnitudes which require more than a single measurement for their complete specification. Take, for instance, a four-sided field which has been duly surveyed. Of what is the measurement of this field to consist? If the number of acres in the field be all that is required then the area is expressed by a simple reference to a number of standard acres. If, however, the entire circumstances of the field are to be brought into view, then a simple statement of the area is not sufficient. It can be easily shown that the surveyor must ascertain five independent quantities before the details of the shape of the field can be adequately defined. Four of these quantities may naturally be the lengths of the four sides of the field, the fifth may be one of the angles, or the area, or the length of one of the diagonals. Speaking generally, we may say that five distinct measurements will be necessary to define the field adequately. The actual choice of the particular measurements to be made is to a great extent arbitrary. The only condition absolutely necessary is that they shall be all independent and free from ambiguity. Once these five quantities are ascertained then all the other features of the figure are absolutely determined. For instance, the four sides and the diagonal being ascertained by measurement, then the other diagonal, the four angles, and the area can all be computed by calculation. The five quantities would determine everything about the field except its actual position on the surface of the earth. If we further desired to have the field exactly localized certain other quantities must be added. The latitude and the longitude of one specified corner of the field would completely indicate that corner, while the azimuth of one side from that corner would complete the definition of its position. We are thus led to see that for the complete delineation of every circumstance relating to the shape of the field and its locality eight different measurements have been required. Two sets of eight measurements differing in any particular can never indicate the same field. It is very important to notice that the *number* of quantities required is quite independent of the particular nature of the measurements adopted. We might for instance have simply measured the latitude and the longitude of each of the four corners of the field. Once these quantities are known, then the shape of the field, its area, its angles, and its diagonals have all been implicitly determined. Here again we see that as two quantities are required to localize each of the four corners, so eight quantities will be required to fully determine the whole field.

In the operations of analytical geometry we are accustomed to specify the position of a point by the relation which it bears to certain fixed axes. By means of certain quantities, either altogether linear or partly linear and partly angular, we are enabled to specify the position of the point with absolute definiteness. These quantities

[1] A translation of this paper was published by Clifford in *Nature* (vol. viii. Nos. 183, 184, pp. 14-17, 36, 37), and has been reprinted in the collected edition of Clifford's *Works*, 1882, pp. 55-69. For a bibliography of higher-space and non-Euclidean geometry, see articles by George Bruce Halsted in the *American Journal of Mathematics Pure and Applied*, i. 261-276, 384, 385; ii. 65-70.

are called the coordinates of the point. In a similar though more extended sense we may use the word "coordinates" to express the group of eight magnitudes which we have found to be adequate to the complete specification of the field. By the measurement of the field in the most complete sense of the term we mean the measurement of its eight coordinates.

Suppose that an object is completely specified by $n$ coordinates, then every different group of $n$ coordinates will specify a different object. The entire group of such objects will form what is called a continuously extended manifoldness. The singly extended manifoldness may be most conveniently illustrated by the conception of time, the various epochs of which are the elements in the manifoldness. Space is a triply extended manifoldness whereof the elements are points. All conceivable spheres form a quadruply extended manifoldness. All conceivable triangles in space form a manifoldness of nine dimensions. The number of coordinates required to specify the position of an element in a manifoldness is thus equal to the order of the manifoldness itself. It is important to observe that the elements of the manifoldness may be themselves objects of no little complexity. Thus, for instance, the conics forming a confocal group constitute the elements of a singly extended manifoldness.

The essential feature of a singly extended manifoldness is that a continuous progress of an element can take place only in two directions, either forwards or backwards. But a singly extended manifoldness may be regarded as itself an element in a manifoldness of a higher order. Thus the points on a circle form a singly extended manifoldness, while the circle itself is one element of the manifoldness which consists of a series of concentric circles. The system of concentric circles may in like manner be regarded as an element in the manifoldness which embraces all systems of concentric circles whose centres lie along a given line. We are thus led to conceive of a multiply extended manifoldness as made up by the successive composition of singly extended manifoldnesses.

It follows from the conception of a manifoldness that in the case of a singly extended manifoldness the position of every element must be capable of being completely specified by a single quantity. It becomes natural to associate with each element of the manifoldness a special numerical magnitude. These magnitudes may vary from $-\infty$ to $+\infty$; to each magnitude will correspond one element of the manifoldness, and conversely each element of the manifoldness is completely specified whenever the appropriate number has been assigned. It is quite possible to have this association of numerical magnitude with the actual position of an element independent of any ordinary metrical relations of the system; it will, however, most usually be found that the numerical magnitudes chosen are such as admit of direct interpretations for the particular manifoldness under consideration. Thus, for instance, in the case of the system of concentric circles it will be natural to associate with each circle its radius, and the position of each circle in the manifoldness will thus be completely defined by the radius. So also in the case of that singly extended manifoldness which consists of colours, it will be natural to employ as the number which specifies each particular colour the wave-length to which that particular colour corresponds.

If the elements of such a manifoldness can receive a simultaneous displacement, then it is plain that to each element in the original position will correspond an element in the second position. Let $x$ and $y$ be the numerical magnitudes correlated to these two elements. Then, since the relation must be of the one-to-one type, it is necessary that the magnitudes $x$ and $y$ must be connected by an equation of the type

$$axy + bx + cy + d = 0.$$

It follows from this that there are a pair of elements which are common to both systems, for if $x = y$ we have the equation

$$ax^2 + (b + c)x + d = 0.$$

The original equation may be written in the form

$$axy + (b - \omega)x + (c + \omega)y + d = 0,$$

and whatever value $\omega$ may have this equation will lead to the same quadratic for the two common elements. We thus have a singly infinite number of displacements which are compatible with the condition that the two fundamental elements shall remain unaltered, and it is displacements of this kind which express the movements of a rigid system.

The position of a point is to be defined by three coordinates. In our ordinary conception of coordinates the position of the point is defined by certain measurements, and thus it would seem that the very mention of coordinates had already presupposed the idea of distance. This, however, need not be the case. We can assume a point in space to be completely defined by three purely numerical quantities. It will be supposed that to each group of three coordinates corresponds one point, and that conversely to one point will correspond three coordinates and no ambiguity is to be present. This latter consideration will exclude from our present view such cases as those where the position of a point is defined by a line and two angles, because angles are subject to a well-known ambiguity amounting to any even multiple of $\pi$. In this case it would not be true that to one point corresponds one set of coordinates, although the converse may be correct.

It is necessary to understand clearly the nature of the suppositions which are made with regard to space by this assumption. Let $x, y, z$ and $x', y', z'$ be the coordinates of two points $a$ and $a'$. Now $x, y, z$ can change continuously by any law into $x', y', z'$. Each intermediate stage will give the coordinates of a point. It must thus be possible to pass continuously in an infinite number of ways from the point $a$ to the point $a'$. We thus assume that space is continuous when we have assumed that its points are represented by coordinates. It must be observed that we predicate nothing as to space which is not involved in the fact that to each point corresponds one group of three coordinates. To some extent the considerations now before us will apply to any other continuous manifoldness which requires three coordinates for the complete specification of its elements. Take, for instance, a musical note. It can be specified accurately by its pitch, intensity, and timbre. These three quantities may be regarded as the three coordinates which will discriminate one sound from the rest. The manifoldness comprising all musical notes is, however, very different from the manifoldness which embraces all the points of space. Each of these manifoldnesses is no doubt continuous, and each of them is of three dimensions, but the conception of distance can have no place in the musical manifoldness. This is due to the absence from the musical manifoldness of anything parallel with the conception of rigidity in the space manifoldness. These remarks will show that the conception of "distance" is something of a special type even in a three-dimensioned continuous manifoldness.

There are also other three-dimensioned and continuous manifoldnesses from which the conception of distance is also absent. Take, for instance, the manifoldness which embraces all the circles that can lie in a given plane. The points of such a manifoldness are the circles. It is three-dimensioned, for two coordinates will be required for the centre of each circle and one for its radius. It is obviously a continuous manifoldness, for one circle may by infinitely graduated modifications pass into any other. Yet from this manifoldness also the conception of distance is absent. There is no intelligible relation of one circle to another

which is analogous to the distance which we require to determine.

We shall now give the investigation of Helmholtz, by which the analytical form of the function expressing the distance is to be ascertained (*Göttingen Nachrichten*, 1868, pp. 193 *sq.*).

It must be remembered that our definition of a point will be purely analytical. Suppose three different scales of pure quantity each extending from $-\infty$ to $+\infty$. Each of these scales is perfectly continuous, so that, no matter how close any two elements in the scale may be, it is always possible to conceive the insertion of an infinite number of intermediate elements. A point is to be defined for our present purpose as a group of three numerical magnitudes taken one from each of the three scales. This conception may be stated more generally. We can conceive $n$ different numerical scales. Then a group of $n$ numbers, one from each scale, will define an element of a continuous $n$-fold manifoldness.

It will be obvious that unless the theory of distance possess a special character it will not be possible for a rigid body to exist. Take, for instance, five points in a rigid body ABCDE. There are ten different pairs of points and ten corresponding distances; all these ten distances must remain unchanged when the body is displaced. We may assume the position of A arbitrarily. Then after the displacement B must be placed at the right distance from A, but will only be limited by this condition to a certain surface, C must be placed at the right distance from A and from B, thus C will be limited to a certain curve. D must be placed at the proper distances from A, from B, and from C. These conditions will be sufficient to define D with complete definiteness. In the same way E will be completely defined by its distances from A, B, and C, but as D and E are thus fully defined we have no guarantee that the distance DE shall retain, after the translation, the same value which it had before. This then indicates that the function which is to express the distance must have a very special form. Any arbitrary function of the six coordinates of the two points would in general not fulfil the condition that the distance DE after the transformation will retain the same value as it had before. If a greater number of points than five be taken, the conditions which a rigid system must fulfil become still more numerous.

Let $x, y, z$ be the coordinates of a point in a rigid body free to rotate around a point. We shall assume that $x, y, z$ is in the vicinity of the fixed point, and that the displacement of the body is such that a second point remains unaltered. In other words, the displacement is to be a rotation around a line joining the two points, and we shall also assume that when this rotation has been completed every point will be restored to its original position. Let $\eta$ be the angle of rotation around the axis, then $x, y, z$ will all be functions of $\eta$, and we may assume that the following equations will hold:—

$$\frac{dx}{d\eta} = a_0x + b_0y + c_0z$$
$$\frac{dy}{d\eta} = a_1x + b_1y + c_1z$$
$$\frac{dz}{d\eta} = a_2x + b_2y + c_2z .$$

In the first place it is plain that these differential coefficients must be functions of $x, y, z$, and, these functions being expanded in ascending powers, we may omit all powers above the first. It will also be obvious that the absolute terms must be zero as the origin is by hypothesis to be a fixed point. As the displacement is a rotation, it follows that the differential coefficients must be zero for certain values of $x, y, z$ different from zero, but this involves the condition

$$\begin{vmatrix} a_0 , & b_0 , & c_0 \\ a_1 , & b_1 , & c_1 \\ a_2 , & b_2 , & c_2 \end{vmatrix} = 0 .$$

We now proceed to solve the three linear differential equations by the well-known process. If we multiply the three equations by $l, m, n$ respectively, and if we determine $l, m, n$ so that

$$lh = la_0 + ma_1 + na_2$$
$$mh = lb_0 + mb_1 + nb_2$$
$$nh = lc_0 + mc_1 + nc_2 ,$$

where $h$ is another constant determined by the equation

$$\begin{vmatrix} a_0 - h , & a_1 , & a_2 \\ b_0 , & b_1 - h , & b_2 \\ c_0 , & c_1 , & c_2 - h \end{vmatrix} = 0 ,$$

the differential equations then give

$$\frac{d}{d\eta}(lx + my + nz) = h(lx + my + nz),$$

whence

$$lx + my + nz = Ce^{h\eta} .$$

We have already seen that one of the values of $h$ must be zero, whence if the other values be $h_1$ and $h_2$ we have the three equations

$$l_0x + m_0y + n_0z = A$$
$$l_1x + m_1y + n_1z = Be^{h_1\eta}$$
$$l_2x + m_2y + n_2z = Ce^{h_2\eta} .$$

It is plain that $h_1$ and $h_2$ cannot be real quantities, for then the quantities $l_1x + m_1y + n_1z$ and $l_2x + m_2y + n_2z$ could attain any values from $-\infty$ to $+\infty$ according to the variations in $\eta$. If $h_1$ and $h_2$ are imaginary then will also the corresponding values of $l, m, n$ be imaginary. We therefore write

$$h_1 = \theta + \omega i \qquad h_2 = \theta - \omega i$$
$$l_1 = \lambda_0 + \lambda_1 i \qquad l_2 = \lambda_0 - \lambda_1 i$$
$$m_1 = \mu_0 + \mu_1 i \qquad m_2 = \mu_0 - \mu_1 i$$
$$n_1 = \nu_0 + \nu_1 i \qquad n_2 = \nu_0 - \nu_1 i$$

so that

$$\lambda_0x + \mu_0y + \nu_0z = Ae^{\theta\eta}\cos(\omega y + c)$$
$$\lambda_1x + \mu_1y + \nu_1z = Ae^{\theta\eta}\sin(\omega y + c) ;$$

in which case we have

$$(\lambda_0x + \mu_0y + \nu_0z)^2 + (\lambda_1x + \mu_1y + \nu_1z)^2 = Ae^{2\theta\eta} .$$

But it is plain that unless $\theta$ be zero the left-hand side of this equation will be susceptible of indefinite increase, which is contrary to our hypothesis. We are therefore entitled to assume that $\theta = 0$. The two roots of the cubic for $h$ must, therefore, be pure imaginaries, and thus we have the condition

$$a_0 + b_1 + c_2 = 0 .$$

Finally we have for the determination of $x, y, z$ the following three equations:—

$$l_0x + m_0y + n_0z = \text{const.}$$
$$\lambda_0x + \mu_0y + \nu_0z = A\cos(\omega y + c)$$
$$\lambda_1x + \mu_1y + \nu_1z = A\sin(\omega y + c) .$$

It will simplify the subsequent calculations if we now make such a transformation of the coordinates as will enable us to write

$$X = l_0x + m_0y + n_0z$$
$$Y = \lambda_0x + \mu_0y + \nu_0z$$
$$Z = \lambda_1x + \mu_1y + \nu_1z .$$

We shall then have from the results just obtained

$$\frac{dX}{d\eta} = 0$$
$$\frac{dY}{d\eta} = -\omega Z$$
$$\frac{dZ}{d\eta} = +\omega Y .$$

The movement corresponding to $\eta$ is such as leaves unaltered all points of which the Y and the Z are equal to zero.

Let us now suppose another displacement to be given to the system by a rotation $\eta'$ about another axis so chosen that all the points for which $X = 0$ and $Z = 0$ shall remain unaltered. For this condition to be fulfilled we must have the equation

$$\frac{dX}{d\eta'} = a_0X + 0 + \nu_0Z$$
$$\frac{dY}{d\eta'} = a_1X + 0 + \nu_1Z$$
$$\frac{dZ}{d\eta'} = a_2X + 0 + \nu_2Z ,$$

for then each side of these equations will be equal to zero for points which make X and Z zero. The condition that the roots of $h$ shall be purely imaginary gives us

$$a_0 + \nu_2 = 0 .$$

If the body receives both the rotation $\eta$ and the rotation $\eta'$ then the joint effect of these two rotations must be equal to that of a single rotation $\phi$, so that

$$\frac{dX}{d\phi}=\frac{dX}{d\eta}+\frac{dX}{d\eta'}$$
$$\frac{dY}{d\phi}=\frac{dY}{d\eta}+\frac{dY}{d\eta'}$$
$$\frac{dZ}{d\phi}=\frac{dZ}{d\eta}+\frac{dZ}{d\eta'};$$

or uniting the two sets of equations we have

$$\frac{dX}{d\phi}=\alpha_0 X+0\ +\nu_0 Z$$
$$\frac{dY}{d\phi}=\alpha_1 X+0\ +(\nu_1-\omega)Z$$
$$\frac{dZ}{d\phi}=\alpha_2 X+\omega Y+\nu_2 Z.$$

As this movement must also be a rotation, the three right-hand members must be capable of being rendered zero for certain values of X, Y, Z, and therefore we have (remembering that $\alpha_0+\nu_2=0$)

$$\begin{vmatrix} \alpha_0 , & 0 , & \nu_0 \\ \alpha_1 , & 0 , & \nu_1-\omega \\ \alpha_2 , & \omega , & -\alpha_0 \end{vmatrix}=0.$$

This condition reduces to

$$\omega\alpha_0(\nu_1-\omega)-\omega\alpha_1\nu_0=0,$$

or
$$\alpha_0\omega^2+\omega(\alpha_1\nu_0-\alpha_0\nu_1)=0.$$

This equation must be satisfied for every value of $\omega$; for, whatever be the amplitudes of the two rotations, they must when compounded be equal to a single rotation. We therefore have the conditions

$$\alpha_0=0$$
$$\alpha_1\nu_0=0.$$

To satisfy the latter condition either $\alpha_1$ or $\nu_0$ must be equal to zero. We must examine which of these two conditions is required by the problem. Since $\alpha_0$ is equal to zero we have

$$\frac{dX}{d\eta'}=\nu_0 Z$$
$$\frac{dY}{d\eta'}=\alpha_1 X+\nu_1 Z$$
$$\frac{dZ}{d\eta'}=\alpha_2 X.$$

If $\nu_0$ were zero then the first equation would show X to be constant; and the result would be that

$$Y=\alpha_1 X\eta+\tfrac{1}{2}\alpha_2\nu_1 X\eta^2+\text{const.};$$

or, in other words, Y would be susceptible of indefinite increase with the increase of $\eta$. The supposition $\nu_0=0$ is therefore precluded, and we are forced to admit that $\alpha_1=0$. The three equations then reduce to

$$\frac{dX}{d\eta'}=\nu_0 Z$$
$$\frac{dY}{d\eta'}=\nu_1 Z$$
$$\frac{dZ}{d\eta'}=\alpha_2 X.$$

If the body receives a rotation $\eta''$ about an axis which leaves X and Y unaltered, we then have

$$\frac{dX}{d\eta''}=f_0 X+g_0 Y+0$$
$$\frac{dY}{d\eta''}=f_1 X+g_1 Y+0$$
$$\frac{dZ}{d\eta''}=f_2 X+g_2 Y+0.$$

The condition that the two roots of $h$ shall be purely imaginary gives us

$$f_0+g_1=0.$$

Let this rotation and the first rotation be communicated together. The resulting rotation could have been produced by a rotation $\chi$, and thus we have

$$\frac{dX}{d\chi}=\frac{dX}{d\eta}+\frac{dX}{d\eta''}$$
$$\frac{dY}{d\chi}=\frac{dY}{d\eta}+\frac{dY}{d\eta''}$$
$$\frac{dZ}{d\chi}=\frac{dZ}{d\eta}+\frac{dZ}{d\eta''}.$$

Substituting, we obtain as before

$$\frac{dX}{d\chi}=f_0 X+g_0 Y+0$$
$$\frac{dY}{d\chi}=f_1 X+g_1 Y-\omega' Z$$
$$\frac{dZ}{d\chi}=f_2 X+(g_2+\omega)Y+0;$$

and as before the condition must be fulfilled

$$\begin{vmatrix} f_0 , & g_0 , & 0 \\ f_1 , & g_1 , & -\omega \\ f_2 , & g_2+\omega , & 0 \end{vmatrix}=0;$$

or, expanding,

$$\omega f_0(g_2+\omega)-\omega f_2 g_0=0.$$

This can only be satisfied for all values of $\omega$ if $f_0=0$ and if

$$f_2 g_0=0.$$

To determine whether $g_0$ can be zero, we have the equations

$$\frac{dX}{d\eta''}=g_0 Y$$
$$\frac{dY}{d\eta''}=f_1 X$$
$$\frac{dZ}{d\eta''}=f_2 X+g_2 Y.$$

It can be shown that if $g_0$ were zero then we should have Z capable of indefinite increase; and hence we see that $f_2$ must be zero, so that the three equations have the form

$$\frac{dX}{d\eta''}=g_0 Y$$
$$\frac{dY}{d\eta''}=f_1 X$$
$$\frac{dZ}{d\eta''}=g_2 Y.$$

Let us now see whether these equations will fulfil the necessary condition for a rotation $\psi$. If

$$\frac{dX}{d\psi}=\frac{dX}{d\eta'}+\frac{dX}{d\eta''}$$
$$\frac{dY}{d\psi}=\frac{dY}{d\eta'}+\frac{dY}{d\eta''}$$
$$\frac{dZ}{d\psi}=\frac{dZ}{d\eta'}+\frac{dZ}{d\eta''},$$

we shall then have by substitution

$$\frac{dX}{d\psi}=0+g_0 Y+\nu_0 Z$$
$$\frac{dY}{d\psi}=f_1 X+0+\nu_1 Z$$
$$\frac{dZ}{d\psi}=\alpha_2 X+g_2 Y+0.$$

But, if this is to represent a rotation,

$$f_1 g_2\nu_0+\alpha_2 g_0\nu_1=0.$$

As this is always to be true, even suppose $g_0$, $f_1$, and $g_2$ for instance were multiplied by a common factor, it is plain that we must have

$$f_1 g_2\nu_0=0$$

and
$$\alpha_2 g_0\nu_1=0.$$

The first condition is to be satisfied by making $g_2$ zero; for neither of the other possible solutions is admissible if the coordinates are to be presented from indefinite increase. In a similar way the second condition requires that $\nu_1$ must be zero.

Resuming now the three groups of equations, they are as follows:—

$$\frac{dX}{d\eta}=0\ ,\quad \frac{dX}{d\eta'}=\nu_0 Z\ ,\quad \frac{dX}{d\eta''}=g_0 Y$$
$$\frac{dY}{d\eta}=-\omega Z\ ,\quad \frac{dY}{d\eta'}=0\ ,\quad \frac{dY}{d\eta''}=f_1 X$$
$$\frac{dZ}{d\eta}=+\omega Y\ ,\quad \frac{dZ}{d\eta'}=\alpha_2 X\ ,\quad \frac{dZ}{d\eta''}=0.$$

Finally let us suppose that the body receives all three motions simultaneously. The resulting motion must still be a rotation, and thus we have the condition

$$\begin{vmatrix} 0 , & g_0 , & \nu_0 \\ f_1 , & 0 , & -\omega \\ \alpha_2 , & +\omega , & 0 \end{vmatrix}=0,$$

which when expanded gives

$$\omega(f_1\nu_0 - a_2 g_0).$$

It is therefore necessary that

$$f_1\nu_0 - a_2 g_0 = 0.$$

But, as this is homogeneous in the two component rotations involved, it does not follow that the separate terms of this equation must necessarily be zero. We satisfy this condition by writing

$$kf_1 = -g_0$$

and

$$ka_2 = -\nu_0.$$

Let the body next receive *any* displacement, $\delta\eta$, $\delta\eta'$, and $\delta\eta''$, then we have in general

$$\delta X = \frac{dX}{d\eta}\delta\eta + \frac{dX}{d\eta'}\delta\eta' + \frac{dX}{d\eta''}\delta\eta'',$$

with similar equations for $\delta Y$ and $\delta Z$.

By substitution these equations become

$$\delta X = -a_2 k Z\delta\eta' - kf_1 Y\delta\eta''$$

$$\delta Y = -\omega Z\delta\eta + f_1 X\delta\eta''$$

$$\delta Z = +\omega Y\delta\eta + a_2 X\delta\eta'.$$

If we multiply the first of these equations by X, the second by $k$Y, and the third by $k$Z, and add, we find

$$X\delta X + kY\delta Y + kZ\delta Z = 0$$

or

$$X^2 + kY^2 + kZ^2 = \text{const.}$$

Here we have attained the fundamental property which the coordinates must satisfy. If $k$ be equal to unity then we have the well-known condition of ordinary space and ordinary rectangular coordinates, but it will be seen that there is nothing in the preceding investigation to make it necessary that $k$ should be unity. There are therefore a singly infinite variety of spaces in which it is possible for a rigid body to be displaced. The different values of $k$ thus correspond to the different "curvatures" which a space might have while it still retained the fundamental property which is necessary for measurement by congruence.

It will now be proper to study the special characteristics of the space with which we are familiar. It has been called flat space or homaloidal space to distinguish it from other spaces in which the curvature is not zero. It is manifest that the characteristic features of our space are not necessarily implied in the general notion of an extended quantity of three dimensions and of the mobility of rigid figures therein. The characteristic features of our space are not necessities of thought, and the truth of Euclid's axioms, in so far as they specially differentiate our space from other conceivable spaces, must be established by experience and by experience only.

The special feature of our space, by which it is distinguished from spherical space on the one hand and pseudo-spherical space on the other hand, depends upon what Riemann calls the measure of curvature. If the sum of the three angles of a triangle is to be two right angles, and if the geometrical similarity of large figures and small figures is to be possible, then the measure of curvature must be zero. Now all measurements that can be made seem to confirm the axiom of parallels and seem to show the measure of curvature of our space to be indistinguishable from zero.

It can be proved that the amount by which the three angles of a triangle would differ from two right angles in curved space depends upon the area of the triangle. The greater the area of the triangle the greater is the difference. To test the famous proposition, Euclid i. 32, it will therefore not be sufficient to measure small triangles. It might be contended that in small triangles the difference between the sum of the three angles and two right angles was so small as to be inextricably mixed up with the unavoidable errors of measurement. Seeing therefore that small triangles obey the law, it is necessary to measure large triangles, and the largest triangles to which we have access are, of course, the triangles which the astronomers have found means of measuring. The largest available triangles are those which have the diameter of the earth's orbit as a base and a fixed star at the vertex. It is a very curious circumstance that the investigations of annual parallax of the stars are precisely the investigations which would be necessary to test whether one of these mighty triangles had the sum of its three angles equal to two right angles. It must be admitted that the parallax-seeking astronomers have never yet found any reason to think that there is any measurable difference. If there were such a difference it would probably be inextricably mixed up with the annual parallax itself. Were space really pseudospherical, then stars would exhibit a real parallax even if they were infinitely distant. Astronomers have sometimes been puzzled by obtaining a negative parallax as the result of their labours. No doubt this has generally or indeed always arisen from the errors which are inevitable in inquiries of this nature, but if space were really curved then a negative parallax might result from observations which possessed mathematical perfection.

It must, however, be remembered that even the triangles of the parallax investigations are utterly insignificant when compared with the dimensions of space itself. Even the whole visible universe must be only an unconceivably small atom when viewed in its true relation to infinite space. It may well be that even with the parallax triangles our opportunities of testing the proposition are utterly inadequate to pronounce on the presence or absence of curvature in space. It must remain an open question whether if we had large enough triangles the sum of the three angles would still be two right angles.

Helmholtz illustrates the subject by considering the representation of space which is obtained in a spherical mirror. A mirror of this kind represents the objects in front of it in apparently fixed positions behind the mirror. The images of the sun and of other distant objects will lie behind the mirror at a distance equal to its focal length, or, to quote the description of Helmholtz—

"The image of a man measuring with a rule a straight line from the mirror would contract more and more the farther he went, but with his shrunken rule the man in the image would count out exactly the same number of centimetres as the real man. And in general all geometrical measurements of lines or angles made with regularly varying images of real instruments would yield exactly the same results as in the outer world. All congruent bodies would coincide on being applied to one another in the mirror as in the outer world. All lines of sight in the outer world would be represented by straight lines of sight in the mirror. In short I do not see how men in the mirror are to discover that their bodies are not rigid solids and their experiences good examples of the correctness of Euclid's axioms. But if they could look out upon our world as we can look into theirs, without overstepping the boundary, they must declare it to be a picture in a spherical mirror, and would speak of us just as we speak of them; and if two inhabitants of the different worlds could communicate with one another, neither so far as I can see would be able to convince the other that he had the true, the other the distorted relations. Indeed I cannot see that such a question would have any meaning at all so long as mechanical considerations are not mixed up with it."

A very important contribution to this subject has been made by Professor Simon Newcomb, entitled "Elementary Theorems Relating to the Geometry of a Space of Three Dimensions and of Uniform Positive Curvature in the Fourth Dimension," see *Jour. f. d. reine und angewandte Math.*, vol. lxxxiii., Berlin, 1877.

He commences by assuming the three following postulates:—

1 "That space is triply extended, unbounded, without properties dependent either upon position or direction, and possessing such planeness in its smallest parts that both the postulates of the Euclidean geometry and our common conceptions of the relations of the parts of space are true for every indefinitely small region in space."

2. "That this space is affected with such curvature that a right line shall always return into itself at the end of a finite and real distance 2D without losing in any part of its course that symmetry with respect to space on all sides of it which constitutes the fundamental property of our conception of it."

3. "That if two right lines emanate from the same point making the indefinitely small angle $\alpha$ with each other, their distance apart

at the distance $r$ from the point of intersection will be given by the equation

$$s = \frac{2aD}{\pi} \sin \frac{r\pi}{2D}.$$"

Newcomb also assumes that two straight lines intersect only in a single point. He defines a "complete right line" as one returning into itself, as supposed in postulate 2. Any small portion of it is to be conceived as a Euclidean right line. The locus of all complete right lines passing through the same point and touching a Euclidean plane through that point will be called a "complete plane."

A "region" will mean any indefinitely small portion of space in which we are to conceive of the Euclidean geometry as holding true.

Newcomb then proceeds to demonstrate the following propositions.

I. All complete right lines are of the same length 2D. Hence D is the greatest possible distance at which the points can be situated, it being supposed that the distance is measured on the line of least absolute length.

II. The complete plane is a Euclidean plane in every region of its extent.

III. Every system of right lines passing through a common point A and making an indefinitely small angle with each other are parallel to each other in the region A′ at distance D.

IV. If a system of right lines pass in the same plane through A the locus of their most distant points will be a complete right line.

V. The locus of all the points at distance D from a fixed point A is a complete plane, and indeed a double plane if we consider as distinct the coincident surfaces in which the two opposite lines meet.

VI. Conversely, all right lines perpendicular to the same complete plane meet in a point at the distance D on each side of the plane.

VII. For every complete right line there is a conjugate complete right line such that every point of the one is at distance D from every point of the other.

VIII. Any two planes in space have as a common perpendicular the right line joining their poles, and intersect each other in the conjugate to that right line.

IX. If a system of right lines pass through a point, their conjugates will be in the polar plane of that point. If they also be in the same plane the conjugates will all pass through the pole of that plane.

X. The relation between the sides $a$, $b$, $c$ of a plane triangle in curved space and their opposite angles A, B, C will be the same as in a Euclidean spherical triangle of which the corresponding sides are $\frac{a\pi}{2D}, \frac{b\pi}{2D}, \frac{c\pi}{2D}$.

XI. Space is finite, and its total volume admits of being definitely expressed by a number of Euclidean solid units which is a function of D.

XII. The total volume of space is $\frac{8D^3}{\pi}$.

XIII. The two sides of a complete plane are not distinct, as in a Euclidean surface.

XIV. If moving along a right line we erect an indefinite series of perpendiculars each in the same Euclidean plane with the one which precedes it, then on completing the line and returning to our starting point, the perpendiculars will be found pointing in a direction the opposite of that with which we started.

Newcomb concludes thus: "It may be also remarked that there is nothing within our experience which will justify a denial of the possibility that the space in which we find ourselves may be curved in the manner here supposed. It might be claimed that the distance of the farthest visible star is but a small fraction of the greatest distance D, but nothing more. The subjective impossibility of conceiving of the relation of the most distant points in such a space does not render its existence incredible. In fact our difficulty is not unlike that which must have been felt by the first man to whom the idea of the sphericity of the earth was suggested in conceiving how by travelling in a constant direction he could return to the point from which he started without during his journey feeling any sensible change in the direction of gravity."

A sketch of the non-Euclidean geometry is given by Professor G. Chrystal in the *Proc. Roy. Soc. Edin.*, vol. x., session 1879–80. The study of this paper is recommended to all who desire to study the elements of what has been called "pangeometry." A more extensive work, which contains the theories of Riemann and Helmholtz, is J. Frischauf's *Elemente der absoluten Geometrie*, Leipsic, 1876.

A fundamental step in the abstract theory of measurement was taken by Professor Cayley in his "Sixth Memoir upon Quantics," *Philosophical Transactions*, vol. cxlix. (1859). The theory thus originated by Cayley has been more fully developed by Klein in his memoir "Ueber die nicht-Euclidische geometrie," *Mathematische Annalen*, vol. iv. p. 573. We shall here enter into this theory in some detail, for in it lies the true foundation of geometrical measurement. A sketch of the theory was given by the author of the present article in *Hermathena*, No. vi. pp. 500–541, Dublin, 1879.

This theory may be regarded merely as a more generalized method of measuring distances and angles in ordinary space, but the results to which it leads are in many respects identical with those to which we are conducted by the theory just discussed. For instance, Newcomb's principle as to the length of the shortest distance between two points never exceeding a certain magnitude is common to his theory and to Cayley's. The theory of Cayley has, however, claims on our attention of a special kind. We here deal with the space with which Euclid has made us familiar, only observing that it is the *measurements* in that space which are to be conducted on a more general principle.

We commence by assuming the existence of a certain surface called the "fundamental quadric," often called "the absolute." By the aid of this quadric and an arbitrary constant $c$ we determine the generalized distance between the points in accordance with the following definition:—

*The distance between two points is equal to $c$ times the logarithm of the anharmonic ratio in which the line joining the two points is divided by the fundamental quadric.*

Let us first test this theory by a very obvious principle which any theory of distance ought to fulfil. It is plain that, if P, Q, R be three collinear points, then in ordinary measurement we ought to have

$$PQ + QR = PR;$$

but it is easy to see that this condition is fulfilled in the generalized measurement. Let the line PQ cut the fundamental quadric in the two points X, Y, then we have

$$PQ = c\log(PX \div PY) - c\log(QX \div QY)$$
$$QR = c\log(QX \div QY) - c\log(RX \div RY)$$
$$PR = c\log(PX \div PY) - c\log(RX \div RY);$$

whence, as in the ordinary measures,

$$PQ + QR = PR.$$

It is also obvious that in the generalized as in the ordinary measures

$$(PQ) = -(QP),$$

and that the distance between the coincident points is equal to zero.

From an obvious property of logarithms we also learn the important fact that the generalized distance between the points is indeterminate to the extent of any integral number of the periods $2ci\pi$.

The distance from any point to its harmonic conjugate with respect to the two fundamental points is equal to $ci\pi$. We thus see that the distance between any two harmonic conjugates is constant. It is usual to make the arbitrary constant $c$ equal to $-i \div 2$, in which case we see that the distance between the two harmonic conjugates is equal to $\pi \div 2$. It can also be shown that, if the two absolute points on a right line coalesce, then the generalized system of measurement degrades to the ordinary system. The two absolute points are at an infinite distance from every other point, so that in the generalized system of measurement every right line has two points at infinity, and in general all the points in space which lie at infinity are situated on the fundamental quadric.

In ordinary geometry we define a circle to be the locus of a point which is at a constant distance from a given point. In the more generalized geometry we retain the same definition of the circle, only observing that the distance to be constant must be expressed in the generalized manner. The plane of course cuts the absolute in a conic section, so that the determination of the circle whose centre is C is the following problem in conic sections:—Through a fixed point O a straight line OP is drawn which cuts a given conic in the points X, Y; determine the locus of P so that the anharmonic ratio (O, P, X, Y) shall remain constant.

This problem is most readily solved by projecting the conic into a circle the centre of which is the projection of O. The problem then assumes the very simple form. On the diameter of a fixed circle a point P′ is taken so that the anharmonic ratio of the four points consisting of P′, the centre O′, and the two points in which the line O′P′ cuts the circle remains constant. It is required to find

the locus of P'. The solution is obvious, and hence we learn that a conic which has double contact with the fundamental conic is a *circle* in the generalized sense, and the centre of that circle is the pole of the chord of contact.

A system of conics which have double contact with the fundamental conic in the same two points form a system of concentric circles, and the centre of the system is the pole of the chord of contact. We are accustomed in ordinary geometry to admit that every circle passes through the two imaginary circular points at infinity. This is the specialized form of the general theorem which asserts that every circle has double contact with the fundamental conic. The two theorems indeed coincide if the fundamental conic degrades to the infinity of ordinary measurement.

A critical case is presented when the chord through O coincides with either of the two tangents which may be drawn from O to the fundamental conic. The two fundamental points then coincide, and hence the distance between any two points on a tangent to the fundamental conic is equal to zero. We have thus the curious result that in every system of concentric circles, including even the fundamental conic itself, the two points common to the system of circles are at the distance zero from the centre of the system. In fact the pair of tangents from the centre may be regarded as a conic having double contact with the fundamental conic, and therefore forming one of the circles of the concentric system of which the radius is zero.

The reader will at once perceive the analogy to a well-known phenomenon in ordinary geometry. The equation in rectangular coordinates

$$x^2+y^2=0$$

denotes *either* a circle of which the radius is zero *or* the pair of lines

$$x\pm\sqrt{-1}y=0;$$

in the latter case we are obliged to admit that the distance of any point on either of these lines from their intersection is equal to zero.

We have now to consider the displacement of a rigid figure, and we shall for the present speak only of a plane movement. We shall first show that it is possible for a plane figure to receive such a displacement that the distance between every two points in the figure after the displacement is equal to what it was before.

Let $x$, $y$, $z$ be the trilinear coordinates of a point in a plane, and suppose that $x'$, $y'$, $z'$ are the coordinates of the position to which this point is transferred in accordance with the linear transformation

$$\begin{aligned} x' &= ax + by + cz \\ y' &= a'x + b'y + c'z \\ z' &= a''x + b''y + c''z. \end{aligned}$$

There are in general three points in the plane which are not altered by this transformation; for, if we assume

$$x'=\rho x, \qquad y'=\rho y, \qquad z'=\rho z,$$

we have for $\rho$ the cubic equation

$$\begin{vmatrix} a-\rho, & b, & c \\ a', & b'-\rho, & c' \\ a'', & b'', & c''-\rho \end{vmatrix} = 0.$$

The three values of $\rho$ which satisfy this equation determine the coordinates of the three points. It is natural to take the sides of the triangle formed by these three points as the three lines of reference, in which case, if $\alpha$, $\beta$, $\gamma$ be constants, the system of equations assume the simple form

$$x'=\alpha x, \qquad y'=\beta y, \qquad z'=\gamma z.$$

It is easily shown that four collinear points before the transformation are collinear after the transformation, and that their anharmonic ratio is unaltered.

This general form of linear transformation must be specialized in order to represent the movement. As no finite movement can either bring a point to infinity or from infinity, it is obvious that the displacement must be such as to leave the fundamental conic unaltered. It is easily seen that the specification of the transformation in its general form requires eight constants; viz., the ratios of the nine quantities $a$, $b$, $c$, $a'$, $b'$, $c'$, $a''$, $b''$, $c''$. We may imagine five of these constants to be disposed of by the provision that the conic shall remain unaltered. There will still remain three disposable constants to give variety to the possible displacements.

Although the fundamental conic will coincide with itself after the transformation, yet it *generally* happens that each point thereon will slide along the conic during the transformation. It is, however, very important to observe that there are two exceptions to this statement.

Let O, A, B, C be four points upon the fundamental conic which by transformation move into the positions O', A', B', C'. If OX be one of the double rays of the systems OA, OB, OC and OA', OB', OC', and if we use the ordinary notation for anharmonic pencils, then we have

$$O(A, B, C, X)=O(A', B', C', X).$$

But the anharmonic ratio subtended by four points on a conic at any fifth point is constant, whence

$$O(A', B', C', X)=O'(A', B', C', X),$$

and therefore

$$O(A, B, C, X)=O'(A', B', C', X).$$

Suppose the transformation moved X to X', then since the anharmonic ratio of a pencil is unaltered by transformation we have

$$O(A, B, C, X)=O'(A', B', C', X');$$

whence

$$O'(A', B', C', X)=O'(A'B'C'X');$$

but this can only be true if the rays O'X and O'X' are coincident, in which case X and X' are coincident, whence it follows that the point X has remained unaltered notwithstanding the transformation. Similar reasoning applies to the point Y defined by the other double ray, and hence we have the following theorem:—

*In that linear transformation of the points in a plane which constitutes a generalized movement, there are two points upon the fundamental conic which remain unchanged.*

It also follows that the tangents to the fundamental conic at the points X and Y, as well as the chord of contact, must remain unaltered. These two tangents and their chord of contact must therefore form the triangle of reference to which we were previously conducted by the general theory of this transformation.

It will now easily appear how a transformation of this kind is really a displacement of a rigid plane. The distance between each pair of points is expressed by an anharmonic ratio; such ratios are unchanged by the transformation, and the two points which lay on the absolute originally are also there after the transformation. It therefore appears that the distance in the generalized sense between every pair of points is unchanged by the transformation. In other words, a rigid system will admit of a displacement of the kind now under consideration.

If we denote the two tangents at the unaltered points on the conic by $x=0$, $y=0$, and the chord of contact by $z=0$, then the equation to the absolute is

$$xy-k^2z^2=0.$$

Transforming this equation by the substitution

$$x'=\alpha x, \qquad y'=\beta y, \qquad z'=\gamma z,$$

we see that the condition $\alpha\beta=\gamma^2$ must be fulfilled.

It is very remarkable that the fundamental conic is only one of a family of conics, each of which remains unaltered by the transformation. In fact every generalized circle of which the intersection of the two tangents is the centre has for its equation $xy-k'z^2$; and, whatever $k$ may be, this circle remains unaltered by the transformation. Hence we have the following remarkable theorem:—

*When a plane rigid system is displaced upon itself there is one point O of the system which remains unaltered, and all the circles which have O as their centre remain unaltered also.*

It is quite natural to speak of this motion as a "rotation," and thus we may assert the truth in generalized measurement of the well-known theorem in ordinary geometry that

*Every displacement of a plane upon itself could have been produced by a rotation of the plane around a certain point in the plane.*

Notwithstanding the rotation of the plane round O, the two tangents from O to the fundamental conic and also their chord of intersection, or the polar of O, remain unaltered; each point on the polar of O is displaced along the polar, and we would in ordinary geometry call this motion a translation parallel to the polar. It thus appears that, in the sense now attributed to the words rotation and translation, a rotation round a point is identical with a translation along the polar of the point.

Another point on which the present theory throws light on the ordinary geometry must be here alluded to. We have seen that the two tangents from O to the fundamental conic remain unchanged during the rotation of the plane round O. It certainly does seem paradoxical to assert that a plane, and all it contains are rotated around a point, and that nevertheless this operation does not alter the position of a certain pair of lines in the plane which pass through the point. But have we not precisely the same difficulty in ordinary geometry? Let us suppose that a plane pencil of rays is rotated through an angle $\theta$ about the origin. Then a line through the origin whose equation before the rotation was

$$x+ky=0$$

becomes after the rotation

$$x\cos\theta+y\sin\theta+k(y\cos\theta-x\sin\theta)=0.$$

The lines thus represented are of course in general different, but they will be the same if

$$1+k^2=0.$$

It follows that even in ordinary geometry the two lines $x\pm iy=0$ remain unaltered notwithstanding the rotation of the plane which

contains them around their intersection. The two lines here referred to are of course those which are drawn through the two circular points at infinity. This paradox is therefore only a degraded form of the property of the tangents to the fundamental conic.

It can also be readily shown that, *if a plane receive two small rotations round two points, then the total rotation produced could have been produced by a single rotation about a certain point on the line joining the two points.*

Let A, B be the two points and P the pole of the line AB, then a rotation round A will displace B along the line PB to an adjacent point B′. The rotation around B will displace A to A′ along the line PA; but, if A′B′ intersects AB in O, then a single rotation about O would have effected the required displacement of A and B, and therefore of the whole line. For, as the point O in the line AB could only move by displacement into the line A′B′, while it can also only move in the direction OP, it must obviously remain unaltered.

We are now in a position to inquire how the magnitude of an angle is to be expressed in the present system of measurement. Our definition of the magnitude of an angle must be made consistent with the supposition that when the angle is carried round by rotation about the vertex the magnitude shall remain unaltered. As anharmonic ratios are unaltered by the rotation, it follows that the anharmonic ratio of the pencil formed by the two legs of the angle and the two tangents to the fundamental conic must remain unaltered. Remembering that the tangents do not move by the rotation, it is natural to choose a function of this anharmonic ratio as the appropriate measure of an angle. The question still remains as to what function should be chosen. The student of ordinary geometry is doubtless aware that the angle between two lines multiplied into $2i$ is equal to the logarithm of the anharmonic ratio of the pencil formed by joining the intersection of the two lines to the two imaginary circular points at infinity. This consideration suggests that the angle between the straight lines in the generalized sense may be appropriately measured by the logarithm of the anharmonic ratio of the pencil formed by the two legs of the angle and the two tangents drawn from their point of intersection to the fundamental conic. There is also a convenience in assuming the angle to be actually *equal* to $c$ times the logarithm of the anharmonic ratio, where $c$ is the same constant as is employed in the expression of the distance. In this case the angle between two lines is by a well-known theorem equal to the distance between their poles. There is here an analogy to a well-known theorem in spherical geometry.

It will now be obvious that, however the angle be situated, its magnitude is unchanged by any displacement of the plane; for, as we have already seen that the displacement does not alter the distance between the poles of the two lines forming the angle, it follows that the magnitude of the angle itself is unaltered.

Just as in the measurement of distance we find a pair of fundamental points on each straight line, so in the measurement of angles we find a pair of fundamental rays in each plane pencil. These rays are the two tangents from the vertex of the pencil to the fundamental conic. In ordinary geometry the two fundamental points on each straight line coalesce into the single point at infinity; but it is exceedingly interesting to observe that even in ordinary geometry the two fundamental rays on each pencil do not coincide. It should also be observed that in the degraded circumstances of ordinary geometry it would be impracticable to employ the *same* constant $c$ for the purpose of both linear and angular measurement.

It is easy to see that the definition of a right angle in the generalized sense is embodied in the statement that "if two corresponding legs of an harmonic pencil touch the fundamental conic then the two other legs are at right angles." We also see that all the perpendiculars to a given line pass through a point, *i.e.*, the pole of the given line; and from a given point a perpendicular can be drawn to a given line by joining the point to the pole of the line. The common perpendicular to two lines is obtained by joining their poles.

The student of modern geometry is already accustomed to think of parallel lines as lines which intersect at infinity, or as lines whose inclination is zero. In speaking of the generalized geometry *in a plane*, we may define that *two straight lines which intersect upon the fundamental conic are parallel.* It thus follows that through any point two distinct parallels can be drawn to a given straight line. The only exception will arise in the case where the given line touches the fundamental conic. This is precisely the case in which the generalized system of measurement degrades to the ordinary system. It will follow that in the present theory of measurement the three angles of a triangle are together not equal to two right angles. In fact, to take an extreme case, we may suppose the three vertices of the triangle to lie upon the fundamental conic. In this case each of the three angles, and therefore their sum, is equal to zero.

A sphere in the generalized system of measurement is the locus of a point which moves at a constant distance from a fixed point. It can therefore be easily shown that a sphere is a quadric which touches the fundamental quadric along its intersection with the polar plane of the centre of the sphere.

In discussing the general case of the displacement of a rigid system it will simplify matters to suppose that the fundamental quadric has real rectilinear generators. It must, however, be understood that the results are not on that account less general. A displacement must not alter the quadric, and must not deform a straight line. Hence it follows that the only effect of a displacement upon a generator of the fundamental quadric will be to convey it to a position previously occupied by a different generator. We shall further suppose that the displacement is such that the two generators to which we have referred belong to the same system. Let A, B, C, D be four generators of the first system which by displacement are brought to coincide with four other generators A′, B′, C′, D′. Let X be one generator of the second system which the displacement brings to X′. Since the anharmonic ratio of the four points in which four fixed generators of the one system are cut by any generator of the other system is constant, we must have, using an obvious notation for anharmonic ratio,

$$X(ABCD) = X'(ABCD);$$

but, since anharmonic ratios are unaltered by displacement, we have

$$X(ABCD) = X'(A'B'C'D'),$$

whence

$$X'(ABCD) = X'(A'B'C'D').$$

It therefore follows that the anharmonic ratio in which four generators cut a fixed generator X′ is equal to the anharmonic ratio in which the four generators after displacement cut the same generator X′.

If P be a generator which passes through one of the double points on X′ determined by the two systems of points in which X′ is cut by the four generators before and after displacement, we must have

$$X(A, B, C, P) = X'(A', B', C', P);$$

hence we see that the generator P will be unaltered by displacement. Similar reasoning applies to the generator which passes through the other double point, and of course to a pair of generators of the second system, and hence we have the following remarkable theorem:—

*In the most general displacement of a rigid system two generators of each of the systems on the fundamental quadric remain unaltered.*

These four fixed generators are the edges of a tetrahedron. Denoting the four faces of this tetrahedron by the equations

$$x = 0,\ y = 0,\ z = 0,\ w = 0,$$

the equation of the fundamental quadric is

$$xz + h^2yw = 0.$$

If the quadric be unaltered by the transformation

$$x' = \alpha x,\ y' = \beta y,\ z' = \gamma z,\ w' = \delta w,$$

then we must have

$$\alpha\gamma = \beta\delta.$$

When this condition is satisfied, then, whatever $h$ may be, every quadric of the family

$$xz + hyw = 0$$

will remain unaltered.

The family of quadrics here indicated are analogous to the right circular cylinders which have for a common axis the screw along which any displacement of a rigid body in ordinary space may be effected.

The two lines

$$x = 0,\ z = 0$$

and

$$y = 0,\ w = 0$$

are conjugate polars with respect to the fundamental quadric, and both these lines are unaltered by the displacement. Hence we see that *in any displacement of a rigid system there are two right lines which remain unaltered, and these lines are conjugate polars with respect to the fundamental quadric.*

Since the pole of a plane through one of these lines lies on the other line, it appears that *a rotation of a rigid system about a straight line is identical with a translation of the system along its conjugate polar.*

Clifford has pointed out the real nature of the lines which are to be called parallel in the generalized system of measurement. We have explained that in the plane two parallel lines intersect upon the fundamental conic; in a certain sense also we may consider two lines in space of three dimensions to be parallel whenever they intersect upon the fundamental quadric. This is the view of parallel lines to which we are conducted by simply generalizing the property that two parallel lines intersect at infinity. But we can take a different definition of two parallel lines. Let us, for example, call two lines parallel when they admit of an indefinitely large number of common perpendiculars. It is exceedingly interesting

to observe that when this condition is fulfilled in the generalized system of measurement the parallel lines so obtained enjoy many of the properties of ordinary parallel lines. The perpendicular distance between such a pair of parallels is constant, and the angles which they make with any common transversal are equal.

It will be shown in a moment that any pair of straight lines which intersect the same two generators of the same system on the fundamental quadric are parallel in this new sense. The fact is that in the degraded circumstances of ordinary geometry two quite different conceptions have become confused. A pair of lines which intersect on the fundamental quadric and a pair of lines which intersect the same pair of generators of the same kind on the fundamental quadric are quite different conceptions; but when the fundamental quadric degrades to the ordinary infinity then the conceptions coalesce, and each of them is merely a pair of parallel lines in the ordinary sense of the word. The ordinary properties of parallel lines have all their analogues in the generalized geometry, but these analogues are distributed between the two original sources of parallels. Clifford proposes to retain the word "parallel" in non-Euclidean space for that conception which exhibits the more remarkable properties of ordinary space, and defines as follows :—

*Straight lines which intersect the same two generators of the same system on the fundamental quadric are parallel.*

Let X and Y be two rectilinear generators of the fundamental quadric belonging to the same system, and let A and B be two straight lines which intersect both X and Y. Since AX and AY are tangent planes their poles must lie on X and Y respectively, and therefore A′ (and B′), the polar of A (and B), must intersect both X and Y. The anharmonic ratio of the four points in which X intersects AB, A′B′ respectively is equal to that of the tangent planes drawn at the points where X intersects A′B′, AB respectively; and, as all these tangent planes contain X, their anharmonic ratio must be equal to that in which they are cut by the line Y. It hence follows that the lines X and Y are divided equianharmonically by the four rays A, B, A′, B′, and therefore the four rays A, B, A′, B′ must be all generators of the same system on an hyperboloid. An infinite number of transversals can therefore be drawn to intersect these four rays, that is to say, an infinite number of common perpendiculars can be drawn to the two rays A and B, and it is easy to show that the lengths of all these perpendiculars are equal.

Clifford has proved the very remarkable theorem that rotations of equal amplitude about two conjugate polars have simply the effect of translating every point operated on through equal distances along parallel lines. This property leads to most important consequences, but it would lead us too far to enter into the subject at present.

A memoir by the present writer on the extension of the theory of screws to space of this description will be found in the *Transactions of the Royal Irish Academy*, vol. xxvii. pp. 157–184.

*Units of Measurement.*—A most excellent account of the units employed in scientific measurements will be found in Professor J. D. Everett's *Units and Physical Constants*, London, 1879. We shall here only give a very brief outline of this branch of the general theory of measurement, referring inquirers to Everett's volume for further details.

Most of the quantities for which measurements are needed can be ultimately expressed by means of (1) a definite length, (2) a definite mass, or (3) a definite interval of time.

It is very important that the units thus referred to should be chosen judiciously, and it must be admitted that the units ordinarily used do not fulfil the conditions which a well-chosen system of units should fulfil. The most scientific system is beyond doubt that which has been suggested by the units committee of the British Association. In this system the unit of length is the *centimetre*, the unit of mass is the *gramme*, and the unit of time is the *second*, and the system is therefore often referred to for brevity as the C.G.S. system. The unit of force is termed the *dyne*, and it is defined to be the force which, acting upon a gramme of matter for a second, generates a velocity of a centimetre per second. The unit of work is the work done by this force working through a centimetre, and this unit is termed the *erg*. The unit of power is the power of doing work at the rate of one erg per second, and the power of an engine can be specified in ergs per second. By the prefixes deca, hecto, kilo, mega, we can express a magnitude equal to the unit multiplied by 10, 100, 1000, or 1,000,000 respectively. On the other hand the prefixes deci, centi, milli, micro, signify the units divided by 10, 100, 1000, or 1,000,000 respectively.

For comparison with the ordinary units the following statements will be useful. The weight of a gramme at any part of the earth's surface is about 980 dynes, or rather less than a kilodyne. The weight of a kilogramme is rather less than a megadyne, being about 980,000 dynes.

The application of these units to electrical and many other measurements will be found in Professor Everett's book already referred to. On the general principles of appliances for measurement, see a paper by Clifford in the *Handbook to the Special Loan Collection of Scientific Apparatus*, 1876, pp. 55–59, reprinted in Clifford's *Mathematical Papers*, pp. 419–23. (R. S. B.)

MEATH, a maritime county of Ireland, in the province of Leinster, is bounded E. by the Irish Sea, S.E. by Dublin, S. by Kildare and King's county, W. by Westmeath, N.W. by Cavan and Monaghan, and N.E. by Louth. Its greatest length north and south is about 40 miles, and its breadth east and west about 45 miles. The total area comprises 578,247 acres, or 904 square miles.

The county forms part of the great limestone plain that occupies the central portion of Ireland. In some districts the surface is variegated by hills and swells, which to the west reach a considerable elevation, although the general features of a fine champaign country are never lost. The coast, which is low and shelving, extends to about 10 miles, but there is no harbour of importance. The Boyne, whose banks are specially beautiful, enters the county at its south-west extremity, and flowing north-east to Drogheda divides it into two almost equal parts. At Navan it receives the Blackwater, which flows south-west from Cavan. The Boyne is navigable for barges as far as Navan, where a canal is carried to Trim. The Royal Canal passes along the southern boundary of the county to Dublin. There are no lakes of importance.

*Climate and Agriculture.*—The climate is genial and favourable for all kinds of crops, there being less rain than even in the neighbouring counties. The principal substratum is limestone, but there are some districts of clay slate. Except a small portion occupied by the Bog of Allen, the county is very verdant and fertile. The soil is principally a rich deep loam resting on limestone gravel, but varies from a strong clayey loam to a light sandy gravel.

The total number of holdings in 1881 was 11,867, of which 1632 were less than 1 acre in extent, and 4300 between 5 and 15 acres. Only 93 were above 500 acres. According to the agricultural statistics for 1881, the area of arable land was 532,708 acres, or 92·4 per cent. of the whole area of the county, while 9599 acres were under plantations, 11,260 bog and marsh, and 201 barren mountain land. Of the arable land, 60,411 were under tillage, 85,893 meadow and clover, and 386,374 pasture. The following table shows the area under the different crops in 1855 and 1882 :—

| | Wheat. | Oats. | Other Cereals. | Potatoes. | Turnips. | Other Green Crops. | Flax. | Meadow and Clover. | Total. |
|---|---|---|---|---|---|---|---|---|---|
| 1855 | 18,764 | 86,831 | 4,876 | 19,235 | 9,904 | 4,005 | 266 | 64,646 | 208,527 |
| 1882 | 2,783 | 31,202 | 1,577 | 12,071 | 6,724 | 3,109 | 59 | 82,572 | 140,097 |

Horses between 1855 and 1882 have diminished from 23,310 to 15,316, an average of 2·9 to every 100 acres under cultivation, the average for Ireland being 3·2. Cattle in 1855 numbered 135,485, and in 1882 had increased to 176,121, an average of 33 to every 100 acres under cultivation, the average for Ireland being 26·2. Sheep in 1855 numbered 170,582, and in 1882 only 146,749, although in 1880 they were 174,573. Pigs in 1882 numbered 19,709, goats 6398, and poultry 318,968.

According to the latest return the land was divided among 1322 proprietors, who possessed 577,846 acres, with a total annual value of £544,550. The average size of the properties was 436 acres, and the average annual value per acre was 18s. 10d. The following four proprietors possessed more than 10,000 acres each : viz., Earl of Darnley, 21,858 acres; J. L. Naper, 18,863; Marquis of Lansdowne, 12,995; and Lord Athlumney, 10,213.

*Manufactures.*—Almost the sole industry of the county is

agriculture, but coarse linen is woven by hand-looms, and there are a few woollen manufactories.

*Railways.*—The Dublin and Meath line intersects the county in a north-westerly direction, and separates into several branches, while the Great Western line skirts the southern boundary.

*Administration and Population.*—The county includes 18 baronies, 146 parishes, and 1626 townlands. Assizes are held at Trim, and quarter sessions at Dunshauglin, Duleek, Kells, Navan, and Trim. Two poor-law unions, Navan and Trim, are wholly within the county, and parts of Ardee, Celbridge, Drogheda, Dunshauglin, Edenderry, Kells, and Old Castle. It is in the Dublin military district, subdistrict of Birr, with barrack stations at Navan and Trim. Ecclesiastically it is in the Meath diocese, with portions in Armagh and Kilmore. Previous to the Union it sent fourteen members to parliament, but now only the two members for the county are returned.

From 81,516 in 1760 the population in 1821 had increased to 159,183, and in 1841 to 183,828, but by 1851 had diminished to 140,768, in 1871 to 95,558, and in 1881 to 87,469, of whom 44,315 were males and 43,154 females. The principal towns are Navan, 3873; Kells, 2822; and Trim, 1586. A portion of the parliamentary borough of Drogheda, including 933 of the inhabitants, is also within the county. The number of births in the county during the ten years ending 3d March 1881 was 21,293, an average of 23·3 to every 1000 of the population; of deaths 16,878, an average of 18·4; of marriages 3165, an average of 3·5; and of emigrants 10,521, an average of 12·1. From 1st May 1851 to 3d March 1881 the total number of emigrants was 49,375. Of the population five years old and upwards in 1881, 22·7 per cent. were illiterate, the percentage in 1871 being 29·9. In 1881 there were 3531 persons able to speak Irish, but none were unable to speak English.

*History and Antiquities.*—According to Ptolemy, Meath was originally inhabited by the Eblani, whose territory extended from the Boyne to the Liffey. A district known as Meath, and including the present county of Meath as well as Westmeath and Longford, with parts of Cavan, Kildare, and King's county, was in the 2d century formed by Tuathal into a kingdom to serve as mensal land of the Ard Rí or over-king. Afterwards it was divided into Oireamhain, now known as Meath, and Eireamhain, which included the remainder of the old kingdom. The district was frequently subject to invasions from the Danes; they were totally defeated at Tara in 980. About 800,000 acres, including all the present county of Meath, was granted by Henry II. to Hugh de Lacy.

The most remarkable antiquarian remains are two round towers, the one at Kells, and the other in the churchyard of Donoughmore, near Navan. At New Grange, near Slane, there is an artificial cavern of a very peculiar construction. A large rath on Tara hill was the meeting-place of the princes before the Danish invasion, and the seat of a royal palace referred to in the well-known lines of Moore. A stone on the top of the rath is supposed by some to be the stone of destiny where the ancient monarchs of Ireland were crowned. Monastic buildings were very numerous, among the more important ruins being those of Duleek, which is said to have been the first ecclesiastical edifice in Ireland built of stone and mortar; the extensive remains of Bective; and those of Clonard, where also were a cathedral and a very famous college. Of the old fortresses, Trim Castle on the Boyne still presents an imposing appearance. There are also many fine old mansions.

MEAUX, capital of an arrondissement, and an episcopal see, in the department of Seine-et-Marne, France, and formerly chief town of Haute Brie, is situated 28 miles east of Paris, on the Marne, which runs through the town, and on the Paris and Strasburg Railway. The cathedral, dedicated to St Stephen, dates from the 12th century; its restoration was begun thirty years ago. From the top of its western tower (250 feet high), in fine weather, the heights of Montmartre and Mont Valérien, near Paris, can be seen. The building, which is 275 feet long and 105 feet high, consists of a nave, two aisles, a fine transept, a choir, and a sanctuary. The choir contains the statue and the tomb of Bossuet, and the pulpit of the cathedral has been reconstructed with the panels of that from which the "Eagle of Meaux" used to preach. The great window of the south transept contains some magnificent stained glass. The episcopal palace, behind the cathedral, has several very curious old rooms; the buildings of the choir school, which also adjoins the cathedral, are likewise of some architectural and archæological interest.

Meaux is the centre of a considerable trade in corn, cheese, eggs, and poultry; and its mills, on the Marne, provide a great part of the meal with which Paris is supplied. The Canal de l'Ourcq, which surrounds the town, and the Marne, furnish the means of transport. A starch manufactory, a copper and iron foundry, and manufactories of food-pastes, of preserved vegetables, and of agricultural implements are the other principal industrial establishments. About a mile from the town is the sugar factory of Villenoy, which is one of the largest in France. The population of Meaux is 11,740.

In the Roman period Meaux was the capital of the Meldi, a small Gallic tribe. It formed part of the kingdom of Austrasia, and afterwards belonged to the counts of Vermandois and Champagne. Its communal charter dates as far back as 1179. Meaux suffered much from the disorders of the Jacquerie, from the Hundred Years' War, and from the religious wars, during which it was an important Protestant centre. After the League, it was the first town which opened its gates to Henry IV., in 1594. Placed as it is on the highroad of invaders marching on Paris from the east of France, Meaux saw its environs ravaged by the army of Lorraine in 1652, and was laid under heavy requisitions in 1814, 1815, and 1870.

MECCA (مكة, *Makka*), the chief town of the Ḥijáz in Arabia,[1] and the great holy city of Islám, is situated two camel marches (the resting-place being Baḥra or Ḥadda in the Baṭn Marr), or about 45 miles, almost due east, from Jidda, on the Red Sea.[2] Thus on a rough estimate Mecca lies in 21° 30′ N. lat. and 40° E. long.

It is said in the Koran (*sur.* xiv. 40) that Mecca lies in a sterile valley, and the old geographers observe that the whole Ḥaram or sacred territory round the city is almost absolutely without cultivation or date palms, while fruit trees, springs, wells, gardens, and green valleys are found immediately beyond. Mecca in fact lies in the heart of a mass of rough hills, intersected by a labyrinth of narrow valleys and passes, and projecting into the Tihámа or low country on the Red Sea, in front of the great mountain wall that divides the coast lands from the central plateau, though in turn they are themselves separated from the sea by a second curtain of hills forming the western wall of the great Wády Marr. The inner mountain wall is pierced by two and only two great passes, and the valleys descending from these embrace on both sides the Mecca hills. The north-western pass, through which the Nejd traffic descends to the coast, and which also affords the easiest though longest route from Jidda and Mecca to Ṭáif and thence through the true Ḥijáz to Yemen, is the Derb el-Seil or torrent path down the well-watered Wády Marr.[3] This Wády skirts the complex of Mecca hills on the north-west from Zeima by Wády Fáṭima (where it is joined by the great coast road from Medina and Syria) to Ḥadda on the Mecca and Jidda road, a distance of perhaps 50 miles. Main roads converge to Mecca from the three points of the Wády just named, the distance of the city from the last two being about 20 miles. From this side the most prominent of the Mecca hills is the northern "Mountain of Light" (J. Núr). The other pass, which affords a shorter mule road to Ṭáif and the southern highlands, but is not practicable for ordinary baggage camels, descends from the summit of J. Kara, and leads through the great W. Na'mán, the Wády of the Hodheil, to the plain beneath 'Arafa, the most

[1] Ḥijáz is here taken in the usual political sense of the word. The Turkish Wály of the Ḥijáz has his winter residence at Mecca and his summer quarters at Ṭáif. In a narrower sense the Ḥijáz is the lofty mountainous country between the central plateau of Nejd (or Negd, as it is called by the natives) and the lowlands of the coast (Tihámа). In this sense El-Asma'í reckons Mecca to the Tihámа, and well-informed Arabs still follow him.

[2] A variant of the name Makka is Bakka (*sur.* iii. 90; Bekrí, 155 *sq.*). For other names and honorific epithets of the city see Bekrí, *ut supra*, Azraḳí, p. 197, Yáḳút, iv. 617 *sq.* The lists are in part corrupt, and some of the names (Kúthá and 'Arsh or 'Ursh, "the huts") are not properly names of the town as a whole.

[3] The upper part of this wády has two branches, W. Leimún and W. Nakhla. In the latter lie the gardens of Sóla and the village of Zeima with its great hot spring (comp. Yáḳút, iii. 197). Above Zeima the path is desert.

easterly of the holy sites connected with Mecca. From this point a tolerably level route skirts the Mecca hills on the south, passing very close to Mecca under the opposite side of J. el-Thaur, is joined or crossed by several roads from the south, including the great lowland Yemen road, and ultimately falls into the road from Mecca to Ḥadda, a little beyond the pillars that define the Ḥaram. The broad valleys through which this southern road leads are not so well watered as W. Marr, but have several fertile spots and a good deal of land cultivable after rain.[1] From this description the importance of the situation of Mecca will be easily understood. It commands both the great routes connecting the lowlands with central Arabia, and thus has the advantage over Ṭáif, its former commercial rival, which lies indeed on the inland mountain road from Yemen to Nejd behind Mount Kara, but has no ready connexion with the Tiháma. Mecca, on the contrary, though apparently secluded in its hills from the main valleys—it is in fact not visible from any point till one is quite close to the town—lies in the focus of all the great roads from north to south or from the coast inland, with the single exception of the mountain road behind Kara; and the low passes that intersect the Mecca hills form a series of practicable short cuts connecting all the chief points of the circle of valleys already described.[2]

Holding this position, and situated in a narrow and barren valley quite incapable of supporting an urban population, Mecca must have been from the first a commercial town.[3] In the palmy days of South Arabia it was probably a station on the great incense route, and thus Ptolemy may have learned the name, which he writes Makoraba. At all events, long before Mohammed we find Mecca established in the twofold quality of a commercial centre and a privileged holy place, surrounded by an inviolable territory (the Ḥaram), which was not the sanctuary of a single tribe but a place of pilgrimage, where religious observances were associated with a series of annual fairs at different points in the vicinity.[4] The combination of commerce with religion was no unusual thing in Arabia. Of old the incense trade had its religious features, and indeed in the unsettled state of the country commerce was possible only under the sanctions of religion, and through the provisions of the sacred truce which prohibited war for four months of the year, three of these being the month of pilgrimage, with those immediately preceding and following. The first of the series of fairs in which the Meccans had an interest was at ʿOkáẓ on the easier road between Mecca and Ṭáif, where there was also a sanctuary, and from it the visiters, drawn from tribes far and near, moved on to points still nearer Mecca (Majanna, and finally Dhu'l-Majáz, on the flank of J. Kabkab behind ʿArafa) where further fairs were held,[5] culminating in the special religious ceremonies of the great feast at ʿArafa, Ḳuzaḥ (Mozdalifa), and Mecca itself. The system of intercalation in the lunar calendar of the heathen Arabs was designed to secure that the feast should always fall at the time when the hides, fruits, and other merchandise were ready for market,[6] and the Meccans, who knew how to attract the Bedouins by profuse and systematic hospitality, bought up these wares in exchange for imported goods, and so became the leaders of the international trade of Arabia. Their caravans traversed the length and breadth of the peninsula. Syria, and especially Gaza, was their chief goal, and we read that the Syrian caravan intercepted, on its return, at Bedr represented capital to the value of £20,000, an enormous sum for those days.[7]

The victory of Mohammedanism made a vast change in the position of Mecca. The merchant aristocracy became satraps or pensioners of a great empire; but the seat of dominion was removed beyond the desert, and though Mecca and the Ḥijáz strove for a time to maintain political as well as religious predominance, as will be related under Mohammedan Empire, the struggle was vain, and terminated on the death of Ibn Zubeyr, the Meccan pretendant to the caliphate, when the city was taken by Ḥajjáj (692 A.D.). On the other hand, the sanctuary and feast of Mecca received a new prestige from the victory of Islám. Purged of elements obviously heathenish, the Kaʿba (Caaba) became the holiest site, and the pilgrimage the most sacred ritual observance of Mohammedanism, drawing worshippers from so wide a circle that the confluence of the petty traders of the desert was no longer the main feature of the holy season. The pilgrimage retained its importance for the commercial wellbeing of Mecca; to this day the Meccans live by the Ḥajj—letting rooms, acting as guides and directors in the sacred ceremonies, as contractors and touts for land and sea transport, as well as exploiting for their own advantage the many benefactions that flow to the holy city; while the surrounding Bedouins derive a chief part of their support from the camel-transport it demands and from the subsidies and gifts by which they are engaged to protect or abstain from molesting the pilgrim caravans. But the ancient "fairs of heathenism" were given up, and the traffic of the pilgrim season, sanctioned by the Prophet in *sur.* ii. 194, was concentrated at Miná and Mecca, where most of the pilgrims still have something to buy or sell, so that Miná, after the sacrifice of the feast day, presents the aspect of a huge international fancy fair.[8] In the Middle Ages this trade was much more important than it is now. Ibn Jubair in the 12th century describes the mart of Mecca in the eight days following the feast as full of gems, unguents, precious drugs, and all rare merchandise from India, ʿIráḳ, Khorásán, and every part of the Moslem world.[9]

Mecca, as has been already indicated, lies in a narrow sandy valley running approximately from north to south between the Red Mountain on the west and the loftier chain of J. Abu Ḳobeys on the east. These ranges, which are partly built on and rise several hundred feet above the valley, so enclose the city that the ancient walls only barred the valley at three points, where three gates led into the town. In the time of Ibn Jubair the gates still stood though the walls were ruined, but now the gates have only left their names to

[1] To this description of the valleys surrounding the Mecca group on three sides, which is mainly drawn from personal observation in 1880, it may be added that there is a direct and easy camel route from Zeima to ʿArafa between the Mecca hills and the mountains of the Hodheil. Taking this fact with the statement of Wáḳidí (Wellhausen's *Muh. in Med.*, p. 341) that every wády in the sacred territory flows outwards into common ground except that at Tanʿim (near the Ḥudúd on the Medina road, Yáḳút, i. 879; Ibn Jubair, p. 110) we see that Mecca lies in an isolated group of hills—a sort of outpost of the great mountain wall.

[2] The inland road in ancient times was not so valuable as the coast road to Syria, on account of the scarcity of water (*Muh. in Med.*, p. 100).

[3] Mecca, says one of its citizens, ap. Wáḳidí (Kremer's ed., p. 196, or *Muh. in Med.*, p. 100), is a settlement formed for trade with Syria in summer and Abyssinia in winter, and cannot continue to exist if the trade is interrupted.

[4] Details as to the inhabitants and constitution of Mecca before Islám will be given under Mohammed.

[5] The details are variously related. See Bírúní, p. 328 (E. T., p. 324); Asmaʿí in Yáḳút, iii. 705, iv. 416, 421; Azraḳí, p. 129 *sq.*; Bekrí, p. 661. Jebel Kabkab is a great mountain occupying the angle between W. Naʿmán and the plain of ʿArafa. The peak is due north of Shedḍád, the hamlet which Burckhardt (i. 115) calls Shedad. According to Azraḳí, p. 80, the last shrine visited was that of the three trees of ʿUzzá in W. Nakhla.

[6] So we are told by Bírúní, p. 62 (E. T., p. 73).

[7] Wáḳidí, ed. Kremer, pp. 20, 21; *Muh. in Med.*, p. 39.

[8] The older fairs were not entirely deserted till the troubles of the last days of the Omayyads (Azraḳí, p. 131).

[9] Ibn Jubair, ed. Wright, p. 118 *sq.*

quarters of the town. At the northern or upper end was the Báb el Ma'lá, or gate of the upper quarter, whence the road continues up the valley towards Miná and 'Arafa as well as towards Zeima and the Nejd. Beyond the gate, in a place called the Ḥajún, is the chief cemetery, said to be the resting-place of many of the companions of Mohammed. Here a cross-road, running over the hill to join the main Medina road from the western gate, turns off to the west by the pass of Kadá, the point from which the troops of the Prophet stormed the city (A.H. 8).[1] Here too the body of Ibn Zubeyr was hung on a cross by Ḥajjáj. The lower or southern gate, at the Masfala quarter, opened on the Yemen road, where the rain-water from Mecca flows off into an open valley. Beyond, there are mountains on both sides; on that to the east, commanding the town, is the great castle, a fortress of considerable strength. The third or western gate, Báb el-'Omra (formerly also Báb el-Záhir, from a village of that name), lay almost opposite the great mosque, and opened on a road leading westwards round the southern spurs of the Red Mountain. This is the way to Wády Fátima and Medína, the Jidda road branching off from it to the left. Considerable suburbs now lie outside the quarter named after this gate; in the Middle Ages a pleasant country road led for some miles through partly cultivated land with good wells, as far as the boundary of the sacred territory and gathering place of the pilgrims at Tan'ím, near the mosque of 'Áisha. This is the spot on the Medína road now called the 'Omra, from a ceremonial connected with it which will be mentioned below.

The length of the sinuous main axis of the city from the furthest suburbs on the Medina road to the suburbs in the extreme north, now frequented by Bedouins, is, according to Burckhardt, 3500 paces.[2] About the middle of this line the longitudinal thoroughfares are pushed aside by the vast courtyard and colonnades composing the great mosque, which, with its spacious arcades surrounding the Ka'ba and other holy places, and its seven minarets, forms the only prominent architectural feature of the city. The mosque is enclosed by houses with windows opening on the arcades and commanding a view of the Ka'ba. Immediately beyond these, on the side facing J. Abu Ḳobeys, a broad street runs south-east and north-west across the valley. This is the Mas'á or sacred course between the eminences of Ṣafá and Merwa, and has been from very early times one of the most lively bazaars and the centre of Meccan life. The other chief bazaars are also near the mosque in smaller streets. The rest of the town presents no points of individual interest, but its general aspect is picturesque; the streets are fairly spacious, though ill-kept and filthy; the houses are all of stone, many of them well-built and four or five stories high, with terraced roofs and large projecting windows as in Jidda—a style of building which has not varied materially since the 10th century (Moḳaddasí, p. 71), and gains in effect from the way in which the dwellings run up the sides and spurs of the mountains. Of public institutions there are baths, ribáṭs or hospices for poor pilgrims from India, Java, &c., a hospital with fifty beds, a public kitchen for the poor, badly administered by the Turkish authorities. A settler from India has recently set up a theological school; but the old colleges around the mosque have long since been converted into lodgings.[3] The minor places of visitation for pilgrims, such as the birth-places of the Prophet and his chief followers, are not notable.[4] Both these and the court of the great mosque are observed to lie beneath the general level of the city, so that it is evident that the site of the town has been gradually raised by accumulated rubbish. The town in fact has little air of antiquity; genuine Arab buildings do not last long, especially in a valley periodically ravaged by tremendous floods when the tropical rains burst on the surrounding hills. The history of Mecca is full of the record of these inundations, unsuccessfully combated by the great dam drawn across the valley by the caliph 'Omar (Ḳuṭb el-Dín, p. 76), and later works of El-Mahdí.[5]

The fixed population of Mecca in 1878 was estimated by Assistant-Surgeon 'Abd el-Razzáḳ at 50,000 to 60,000; but the materials for an estimate are very inadequate where there is so large a floating population—and that not merely at the proper season of pilgrimage, the pilgrims of one season often beginning to arrive before those of the former season have all dispersed. At the height of the season the town is much overcrowded, and the entire want of a drainage system is severely felt. Fortunately good water is tolerably plentiful; for, though the wells are mostly undrinkable, and even the famous Zamzam water very unwholesome and tainted with sewage, the underground conduit from beyond 'Arafa, completed by Sultan Selim II. in 1571, supplies to the public fountains a sweet and light water, containing, according to 'Abd el-Razzáḳ, a large amount of chlorides. The water is said to be free to townsmen, but is sold to the pilgrims at a rather high rate.[6]

Mediæval writers celebrate the copious supplies, especially of fine fruits, brought to the city from Táif and other fertile parts of Arabia. These fruits are still famous; rice and other foreign products are brought by sea to Jidda; mutton is plentifully supplied from the desert.[7] The industries of Mecca all centre in the pilgrimage; the chief object of every Meccan—from the notables and sheikhs, who use their influence to gain custom for the Jidda speculators in the pilgrim traffic, down to the cicerones, pilgrim brokers, lodging-house keepers, and semi-mendicant hangers on at the holy places—being to pillage the visiter in every possible way. Thus the fanaticism of the Meccan is an affair of the purse; the mongrel population (for the town is by no means purely Arab) has exchanged the virtues of the Bedouin for the worst corruptions of Eastern town life, without casting off the ferocity of the desert, and it is hardly possible to find a worse certificate of character than the three parallel gashes on each cheek, called Tashrít, which are the customary mark of birth in the holy city. The unspeakable vices of Mecca are a scandal to all Islám, and a constant source of wonder to pious pilgrims.[8] The slave trade, which still

[1] This is the cross-road traversed by Burckhardt (i. 109), and described by him as cut through the rocks with much labour.

[2] Istrakhrí gives the length of the city proper from north to south as 2 miles, and the greatest breadth from the Jiyád quarter east of the great mosque across the valley and up the western slopes as two-thirds of the length.

[3] The pious foundations of Mecca have been robbed by their guardians from very early times. See already Ibn Haukal, p. 25.

[4] For details as to the ancient quarters of Mecca, where the several families or septs lived apart from generation to generation, see Azrakí, p. 445 *sq.*, and compare Ya'kubí, ed. Juynboll, p. 100. The modern town is best described by Burckhardt, who gives a plan of the city. The minor sacred places are described at length by Azrakí and Ibn Jubair. They are either connected with genuine memories of the Prophet and his times, or have spurious legends to conceal the fact that they were originally holy stones, wells, or the like, of heathen sanctity.

[5] Beládhorí, in his chapter on the floods of Mecca (p. 53 *sq.*), says that 'Omar built two dams.

[6] The aqueduct is the successor of an older one associated with the names of Zobeyda, wife of Harún el-Rashíd, and other benefactors. But the old aqueduct was frequently out of repair, and seems to have played but a secondary part in the mediæval water supply. Even the new aqueduct gave no adequate supply in Burckhardt's time.

[7] In Ibn Jubair's time (p. 132) large supplies were brought from the Yemen mountains. The revenues of Yemen are still mainly expended on the distribution of grain by the sultan in the Hijáz.

[8] The corruption of manners in Mecca is no new thing. See the letter of the caliph Mahdí on the subject; Wüstenfeld, *Chron. Mek.*, iv. 168.

subsists and is very dear to the Arab heart, has connexions with the pilgrimage which are not yet thoroughly cleared up; but there is no doubt that under cover of the pilgrimage a great deal of kidnapping and importation of slaves goes on.

Since the fall of Ibn Zubeyr the political position of Mecca has always been dependent on the movements of the greater Mohammedan world. In the splendid times of the caliphs immense sums were lavished upon the pilgrimage and the holy city; and conversely the decay of the central authority of Islám brought with it a long period of faction, wars, and misery, in which the most notable episode was the sack of Mecca, with circumstances of great barbarity, by the Carmathians at the pilgrimage season of 930 A.D. The victors carried off the "black stone," which was not restored for twenty-two years, and then only for a great ransom, when it was plain that even the loss of the palladium could not destroy the sacred character of the city. Under the Fatimites Egyptian influence began to be strong in Mecca; it was opposed by the sultans of Yemen, while native princes claiming descent from the Prophet—the Háshimite emírs of Mecca, and after them the emírs of the house of Ḳatáda (since 1202)—attained to great authority and aimed at independence; but soon after the final fall of the Abbasids the Egyptian overlordship was definitively established by Sultan Bíbars (1269 A.D.). The Turkish conquest of Egypt transferred the supremacy to the Ottoman sultans (1517), who treated Mecca with much favour, and during the 16th century executed great works in the sanctuary and temple. The Ottoman power, however, became gradually almost nominal, and that of the emírs or sherífs increased in proportion, culminating under Ghálib, whose accession dates from 1786. Then followed the wars of the Wahhábís (see ARABIA, vol. ii. p. 260) and the restoration of Turkish rule by the troops of Mohammed Alí. By him the dignity of sherif was deprived of much of its weight, and in 1827 a change of dynasty was effected by the appointment of Ibn ʿAun. Since that time the Turkish authority has again decayed, though Mecca is still nominally the capital of a Turkish province, and has a governor-general and a Turkish garrison, while Mohammedan law is administered by a judge sent from Constantinople. But, except within the larger towns, at which troops are stationed, the Turks are practically powerless, and the real sovereign of Mecca and the Ḥijáz is the sherif, who, as head of a princely family claiming descent from the Prophet, holds a sort of feudal position in the country. The dignity of sherif (or grand sherif, as Europeans usually say for the sake of distinction, since all the kin of the princely houses reckoning descent from the Prophet are also named sherífs), is often conceived as a religious pontificate, and anti-Turkish Arabs contend that if the sultan and the sherif were together in a mosque the latter would lead the prayers as imám; but it is more correct to regard the sherif as the modern counterpart of the ancient emírs of Mecca already referred to, who were named in the public prayers immediately after the reigning caliph. This dignity long ran in the family of Ḥasan, son of the caliph ʿAlí, with which the present sherífs, in spite of changes of dynasty, still count kindred. The influence of the princes of Mecca has varied from time to time according to the strength of the foreign protectorate in the Ḥijáz or in consequence of feuds among the branches of the house; at present it is for most purposes much greater than that of the Turks. The latter are strong enough to hold the garrisoned towns, and thus the sultan is able within certain limits—playing off one against the other the two rival branches of the aristocracy, viz., the kin of Ghálib and the house of Ibn ʿAun—to assert the right of designating or removing the sherif, to whom in turn he owes the possibility of maintaining, with the aid of considerable pensions, the semblance of his much-prized lordship over the holy cities. The grand sherif can muster a considerable force of freedmen and clients, and his kin, holding wells and lands in various places through the Ḥijáz, act as his deputies and administer the old Arabic customary law to the Bedouins. To this influence the Ḥijáz owes what little of law and order it enjoys. After the sherífs the principal family of Mecca is the house of Sheyb, which holds the hereditary custodianship of the Kaʿba.

*The Great Mosque and the Kaʿba.*—Long before Mohammed the chief sanctuary of Mecca was the Kaʿba, a rude stone building, so named from its resemblance to a monstrous *astragalus* or die, of about 40 feet cube, though the shapeless mass is not really an exact cube or even exactly rectangular.[1] The Kaʿba has been rebuilt more than once since Mohammed purged it of idols and adopted it as the chief sanctuary of Islám, but the old form has been preserved except in secondary details;[2] so that the "Ancient House," as it is titled, is still essentially a heathen temple, adapted to the worship of Islám by the clumsy fiction that it was built by Abraham and Ishmael by divine revelation as a temple of pure monotheism, and that it was only temporarily perverted to idol worship from the time when ʿAmr ibn Lohay introduced the statue of Hobal from Syria[3] till the victory of Islám. This fiction has involved the superinduction of a new mythology about Abraham, Hagar, and Ishmael over the old heathen ritual, which remains practically unchanged. Thus the chief object of veneration is the ancient fetish of the black stone, which is fixed in the external angle facing Ṣafá. The building is not exactly oriented, but this may for convenience be called the south-east corner. Its technical name is the black corner, the others being named the Yemen (south-west), Syrian (north-west), and ʿIráḳ (north-east) corners, from the lands to which they approximately point. The black stone is a small dark mass a span long, with an aspect suggesting volcanic or meteoric origin, fixed at such a height that it can be conveniently kissed by a person of middle size. It was broken by fire in the siege of 683 A.D. (not as many authors relate by the Carmathians), and the pieces are kept together by a silver setting. The history of this heavenly stone, given by Gabriel to Abraham, does not conceal the fact that it was originally a fetish, the most venerated of a multitude of idols and sacred stones which stood all round

[1] The following measurements may be cited:—Ibn ʿAbd Rabbih (10th century), south side 20 cubits, north 21, east and west 25 each (so Azraḳí); Ibn Jubair (12th century), sides 54 and 48 spans, height 29 cubits at the highest or south wall, with a slight fall to the north side where the mízáb or water-spout discharges (Azraḳí, 27 cubits); Burckhardt, sides 18 paces by 14, height 35 to 40 feet. Other modern measures vary considerably. The height was raised by Ibn Zubeyr from 18 to 27 cubits. Compare *Muh. in Med.*, p. 426.

[2] The Kaʿba of Mohammed's time was itself the successor of an older building said to have been destroyed by fire. It was constructed in the still usual rude style of Arabic masonry, with string courses of timber between the stones (like Solomon's temple). The roof rested on six pillars; the door was raised above the ground and approached by a stair (probably on account of the floods which often swept the valley); and worshippers left their shoes under the stair before entering. During the first siege of Mecca (683 A.D.) the building was burned down, and Ibn Zubeyr reconstructed it on an enlarged scale and in better style of solid ashlar work. After his death his most glaring innovations (the introduction of two doors on a level with the ground, and the extension of the building lengthwise to include the Ḥijr) were corrected by Ḥajjáj under orders from the caliph, but the building retained its more solid structure. The roof now rested on three pillars, and the height was raised one-half. The Kaʿba was again entirely rebuilt after the flood of 1626 A.D., but since Ḥajjáj there seem to have been no structural changes.

[3] Hobal was set up within the temple over the pit that contained the sacred treasures. His chief function was connected with the sacred lot to which the Meccans were accustomed to betake themselves in all matters of difficult

the sanctuary in the time of Mohammed. The Prophet destroyed the idols, but he left the characteristic form of worship—the *ṭawáf*, or sevenfold circuit of the sanctuary, the worshipper kissing or touching the objects of his veneration—and besides the black stone he recognized the so-called "southern" stone, the same presumably with that which is still touched in the ṭawáf at the Yemen corner (*Muh. in Med.*, pp. 336, 425). The ceremony of the ṭawáf and the worship of stone fetishes was common to Mecca with other ancient Arabian sanctuaries.[1] It was, as it still is, a frequent religious exercise of the Meccans, and the first duty of one who returned to the city or arrived there under a vow of pilgrimage; and thus the outside of the Ka'ba was and is more important than the inside. Islám did away with the worship of idols; what was lost in interest by their suppression has been supplied by the invention of spots consecrated by recollections of Abraham, Ishmael, and Hagar, or held to be acceptable places of prayer. Thus the space of ten spans between the black stone and the door, which is on the east side, between the black and 'Iráḳ corners, and a man's height from the ground, is called the *Multazam*, and here prayer should be offered after the ṭawáf with outstretched arms and breast pressed against the house. On the other side of the door, against the same wall, is a shallow trough which is said to mark the original site of the stone on which Abraham stood to build the Ka'ba. Here the growth of the legend can be traced, for the place is now called the "kneading-place" (Ma'jan), where the cement for the Ka'ba was prepared. This name and story do not appear in the older accounts. Once more, on the north side of the Ka'ba, there projects a low semicircular wall of marble with an opening at each end between it and the walls of the house. The space within is paved with mosaic, and is called the Ḥijr. It is included in the ṭawáf, and two slabs of *verde antico* within it are called the graves of Ishmael and Hagar, and are places of acceptable prayer. Even the golden or gilded *mízáb* (waterspout) that projects into the Ḥijr marks a place where prayer is heard, and another such place is the part of the west wall close to the Yemen corner.

The feeling of religious conservatism which has preserved the structural rudeness of the Ka'ba through so many centuries did not interfere with the adoption of costly surface decoration. In Mohammed's time the outer walls were covered by a vail (or *kiswa*) of striped Yemen cloth. The magnificence of the caliphs substituted a covering of figured brocade, and the sultan still sends with each pilgrim caravan from Cairo a new kiswa of black brocade, adorned with a broad band embroidered with golden inscriptions from the Koran, as well as a richer curtain for the door. The aspect thus given to the Ka'ba is seen in the woodcut; there are openings to show the two sacred stones.[2] The door of two leaves, with its posts and lintel, is of silver gilt.

The interior of the Ka'ba is now opened but a few times every year; there is a great scramble for admission—the portable staircase being seldom brought forward—and a great clamour for backshish; thus the modern descriptions, from observations made under difficulties, are not very complete. Little change, however, seems to have been made since the time of Ibn Jubair, who describes the floor and walls as overlaid with richly variegated marbles, and the upper half of the walls as plated with silver thickly gilt, while the roof was vailed with coloured silk. Modern writers describe the place as windowless, but Ibn Jubair mentions five windows of rich stained glass from 'Iráḳ. Between the three pillars of teak hung thirteen silver lamps. A chest in the corner to the left of one entering contained Korans, and at the 'Iráḳ corner a space was cut off enclosing the stair that leads to the roof. The door to this stair (called the door of mercy—Báb el-Raḥma) was plated with silver by the caliph Mutawakkil. Here, in the time of Ibn Jubair, the Maḳám or standing-stone of Abraham was usually placed for better security, but brought out on great occasions (pp. 131, 161).[3]

The houses of ancient Mecca pressed close upon the Ka'ba, the noblest families, who traced their descent from Ḳoṣay, the reputed founder of the city, having their dwellings immediately round the sanctuary. To the north of the Ka'ba was the Dár el-Nadwa, or place of assembly of the Ḳoreysh, where all matters of public interest were discussed. The multiplication of pilgrims after Islám soon made it necessary to clear away the nearest dwellings and enlarge the place of prayer around the Ancient House. 'Omar, 'Othmán, and Ibn Zubeyr had all a share in this work, but the great founder of the mosque in its present form, with its spacious area and deep colonnades, was the caliph El-Mahdí, who spent enormous sums in bringing costly pillars from Egypt and Syria. The work was still incomplete at his death in 785 A.D., and was finished in less sumptuous style by his successor. Subsequent repairs and additions, extending down to Turkish times, have left little of El-Mahdí's work untouched, though a few of the pillars probably date from his days. There are more than five hundred pillars in all, of very various style and workmanship, and the enclosure—250 paces in length and 200 in breadth, according to Burckhardt's measurement—is entered by nineteen archways irregularly disposed.

After the Ka'ba the principal points of interest in the mosque are the well Zamzam and the Maḳám Ibráhím. The former is a deep shaft enclosed in a massive vaulted building paved with marble, and, according to Mohammedan tradition, is the source (corresponding to the Beer-lahai-roi of Gen. xvi. 14) from which Hagar drew water for her son Ishmael. This of course is pure invention, and indeed the legend tells that the well was long covered up and rediscovered by 'Abd el-Muṭṭalib, the grandfather of the Prophet. Sacred wells are familiar features of Semitic sanctuaries, and Islám, retaining the well, made a quasi-Biblical story for it, and endowed its tepid waters with miraculous curative virtues. They are eagerly drunk by the pilgrims, or when poured over the body are held to give a miraculous refreshment after the fatigues of religious exercise, and the manufacture of bottles or jars for carrying the water to distant countries is quite a trade. Ibn Jubair (p. 139) mentions a curious superstition of the Meccans, who believed that the water rose in the shaft at the full moon of the month Sha'bán. On this occasion a great crowd, especially of young people, thronged round the well with shouts of religious enthusiasm, while the servants of the well dashed buckets of water over their heads. The Maḳám or standing place of Abraham is also connected with a relic of heathenism, the ancient holy stone which once stood on the Ma'jan, and is said to bear the prints of the patriarch's

[1] See Ibn Hishám, i. 54; Azraḳí, p. 80 ('Uzzá in Batn Marr); Yáḳút, iii. 705 (Otheydá); Bar Hebræus on Psalm xii. 9. Stones worshipped by circling round them bore the name *dawár* or *duwár* (Krehl, *Rel. d. Araber*, p. 69). The later Arabs not unnaturally viewed such cultus as imitated from that of Mecca (Yáḳút, iv. 622; comp. Dozy, *Israeliten te Mekka*, p. 125, who draws very perverse inferences).

[2] The old *kiswa* is removed on the 25th day of the month before the pilgrimage, and fragments of it are bought by the pilgrims as charms. Till the 10th day of the pilgrimage month the Ka'ba is bare.

[3] Before Islám the Ka'ba was opened every Monday and Thursday; in the time of Ibn Jubair it was opened with considerable ceremony every Monday and Friday, and daily in the month Rajab. But, though prayer within the building is favoured by the example of the Prophet, it is not compulsory on the Moslem, and even in the time of Ibn Batúta the opportunities of entrance were reduced to Friday and the birthday of the Prophet.

feet. The whole legend of this stone, which is full of miraculous incidents, seems to have arisen from a misconception, the Maḳám Ibráhím in the Korán meaning the sanctuary itself; but the stone, which is a block about 3 spans in height and 2 in breadth, and in shape "like a potter's furnace" (Ibn Jubair), is certainly very ancient. It is now covered up, and no one is allowed to see it, though the box in which it lies can be seen or touched through a grating in the little chapel that surrounds it. In the Middle Ages it was sometimes shown, and Ibn Jubair describes the pious enthusiasm with which he drank Zamzam water poured on the footprints. It was covered with inscriptions in an unknown character, one of which was copied by Fákihí in his history of Mecca. To judge by the facsimile in Dozy's *Israeliten te Mekka*, the character is probably essentially one with that of the Syrian Ṣafá inscriptions, which we now know to have extended through the Nejd and into the Ḥijáz.[1]

The general aspect of the great mosque will be best understood by reference to the woodcut, which is taken from a photograph. The photographer has taken his stand on a lofty building facing the black stone corner of the Ka'ba, so that house tops, with high parapets serving to protect the privacy of the women, who spend much of their time on these terraces, form too prominent a feature in the foreground, and obstruct the view of part of the cloistered area. The background is the Red Mountain; the fort which is seen above the town is not the great castle but a building of the sherif Ghálib, dating from about the beginning of this century. It will be observed that at two places there are smaller cloistered courts annexed to the main colonnade. That to the right, with a polygonal minaret, corresponds to the ancient Dár el-Nadwá, which was included in the mosque by the caliph Mo'taḍid. The other minor court is at the Báb Ibráhím. Of the two walls of the Ka'ba concealed from view, that to the right is the one adjoining the Hijr. The two-storied pagoda-like building facing this wall is the Makám or station for prayer of orthodox Moslems of the Ḥanafí rite, to which the Turks belong. The similar stations of the other orthodox sects have but one story; that of the Málikí rite is seen to the left of the Ka'ba; the roof of the Ḥanbalí station is just visible in the foreground a little to the left of the "black" corner; the Sháfi'í station, which stands on the roof of the Zamzam building, is more prominent a little to the right. Between this and the Makám Ḥanafí rises the slender gilt spire of the white marble pulpit from which sermons are preached on Fridays and high days. Between the pulpit and the Zamzam is the small chapel of Abraham's stone. It does not rise high enough to be seen in the cut. The two small and ugly domes to the right of the Zamzam are the dome of 'Abbás and the dome of the Jewess. They are used as storerooms, but the former, which has its name from the uncle of the Prophet, was formerly the drinking-place of the pilgrims. In the time of Ibn Jubair it was still used for cooling the Zamzam water. The oval part of the court next to the Ka'ba within the railing is paved with marble; parts of the area beyond are also paved, part being strewn with gravel. Around the railing a number of glass lamps are lighted at night.

*Ṣafá and Merwa.*—In religious importance these two points or "hills," connected, as we have seen, by the Mas'á, stand second only to the Ka'ba. Ṣafá is an elevated platform surmounted by a triple arch, and approached by a flight of steps.[2] It lies south-east of the Ka'ba, facing the black corner, and 76 paces from the "Gate of Ṣafá," which is architecturally the chief gate of the mosque. Merwa is a similar platform, formerly covered with a single arch, on the opposite side of the valley. It stands on a spur of the Red Mountain called J. Ḳu'ayḳi'án. The course between these two

Mecca—the Great Mosque.

sacred points is 493 paces long, and the religious ceremony called the "sa'y" consists in traversing it seven times, beginning and ending at Ṣafá. The lowest part of the course, between the so-called green milestones, is done at a run. This ceremony, which, as we shall presently see, is part of the 'omra, is generally said to be performed in memory of Hagar, who ran to and fro between the two eminences vainly seeking water for her son. The observance, however, is certainly of pagan origin; and at one time there were idols on both the so-called hills (see especially Azraḳí, pp. 74, 78).

*The Ceremonies and the Pilgrimage.*—Before Islám the Ka'ba was the local sanctuary of the Meccans, where they prayed and did sacrifice, where oaths were administered and hard cases submitted to divine sentence according to the immemorial custom of Semitic shrines. But besides this, as we have seen, Mecca was already a place of pilgrimage. Pilgrimage with the ancient Arabs was the fulfilment of a vow, which appears to have generally terminated—at least on the part of the well-to-do—in a sacrificial feast. A vow of pilgrimage might be directed to other sanctuaries than Mecca—the technical word for it (ihlál) is applied for example to the pilgrimage to Manát (Bekrí, p. 519). He who was under such a vow was bound by ceremonial observances of abstinence from certain acts (*e.g.*, hunting) and sensual pleasures, and in particular was forbidden to shear or comb his hair till the fulfilment of the vow. This old Semitic usage has its close parallel in the vow of the Nazarite. It was not peculiarly connected with Mecca; at Ṭáif, for example, it was customary on return to the city after an absence to present oneself at the sanctuary, and there shear the hair (*Muh. in Med.*, p. 381). Pilgrimages to Mecca were not tied to a single time, but they were naturally associated with festive occasions, and especially with the great annual feast and market already spoken of, when by extensive hospitality the citizens did all in their power to attract the worshippers who were at the same time their customers. The pilgrimage was so intimately connected with the wellbeing of Mecca, and had already such a hold on the Arabs round about, that the politic Mohammed could not afford to sacrifice it to an abstract purity of religion, and thus the old usages were transplanted into Islám in the double form of the 'omra or vow of pilgrimage to Mecca, which can be discharged at any time, and the ḥajj or pilgrimage at the great annual feast. The latter closes with a visit to the Ka'ba, but its essential ceremonies lie outside Mecca, at the neighbouring shrines where the old Arabs gathered before the Meccan fair.

The 'omra begins at some point outside the Haram or holy territory, generally at Tan'ím described above, both for convenience sake and because 'Áisha began the 'omra there in the year 10 of the Flight. The pilgrim enters the Haram in the antique and scanty pilgrimage dress (iḥrám), consisting of two cloths wound round his person in a way prescribed by ritual. His devotion is expressed in

[1] See De Vogué, *Syrie Centrale: Inscr. Sem.*; Lady Anne Blunt, *Pilgrimage to Nejd*, vol. ii.; and W. R. Smith, in the *Athenæum*, March 20, 1880.

[2] Ibn Jubair speaks of fourteen steps, Aly Bey of four, Burckhardt of three. The surrounding ground no doubt has risen so that the old name "hill of Ṣafá" is now inapplicable.

shouts of Labbeyka (a word of obscure origin and meaning); he enters the great mosque, performs the ṭawáf and the sa'y[1] with circumstances and prayers which it is unnecessary to detail, and then has his head shaved and resumes his common dress. This ceremony is now generally combined with the ḥajj, or is performed by every stranger or traveller when he enters Mecca, and the iḥrám (which involves the acts of abstinence already referred to) is assumed at a considerable distance from the city. But it is also proper during one's residence in the holy city to perform at least one 'omra from Tan'ím in connexion with a visit to the mosque of 'Áisha there. The absurd triviality of these rites is ill concealed by the legends of the sa'y of Hagar and of the ṭawáf being first performed by Adam in imitation of the circuit of the angels about the throne of God; but in truth the meaning of their ceremonies seems to have been almost a blank to the Arabs before Islám, whose religion had become a mere formal tradition. We do not even know to what deity the worship expressed in the ṭawáf was properly addressed. There is a tradition that the Ka'ba was a temple of Saturn (Shahrastáni, p. 431); perhaps the most distinctive feature of the shrine may be sought in the sacred doves which still enjoy the protection of the sanctuary. These recall the sacred doves of Ascalon (Philo, vi. 200 of Richter's ed.), and suggest Venus-worship as at least one element (comp. Herod., i. 131; iii. 8; Ephr. Syr., *Op. Syr.*, ii. 457).

To the ordinary pilgrim the 'omra has become so much an episode of the ḥajj that it is often described as a mere visit to the mosque of 'Áisha; a better conception of its original significance is got from the Meccan feast of the seventh month (Rajab) graphically described by Ibn Jubair from his observations in 1184 A.D. Rajab was one of the ancient sacred months, and the feast, which extended through the whole month, and was a joyful season of hospitality and thanksgiving, no doubt represents the ancient feasts of Mecca more exactly than the ceremonies of the ḥajj, in which old usage has been overlaid by traditions and glosses of Islám. The 'omra was performed by crowds from day to day, especially at new and full moon.[2] The new moon celebration was nocturnal; the road to Tan'ím, the Mas'á, and the mosque were brilliantly illuminated; and the appearing of the moon was greeted with noisy music. A genuine old Arab market was held, for the wild Bedouins of the Yemen mountains came in thousands to barter their cattle and fruits for clothing, and deemed that to absent themselves would bring drought and cattle plague in their homes. Though ignorant of the legal ritual and prayers, they performed the ṭawáf with enthusiasm, throwing themselves against the Ka'ba and clinging to its curtains as a child clings to its mother. They also made a point of entering the Ka'ba. The 29th of the month was the feast day of the Meccan women, when they and their little ones had the Ka'ba to themselves without the presence even of the Sheybís.

The central and essential ceremonies of the ḥajj or greater pilgrimage are those of the day of 'Arafa, the 9th of the "pilgrimage month" (Dhu'l Ḥijja), the last of the Arab year; and every Moslem who is his own master, and can command the necessary means, is bound to join in these once in his life. By them the pilgrim becomes as pure from sin as when he was born, and gains for the rest of his life the honourable title of ḥájj. Neglect of other parts of the pilgrim ceremonial may be compensated by offerings, but to miss the "stand" (wokúf) at 'Arafa is to miss the pilgrimage. 'Arafa or 'Arafát is a space artificially limited, round a small isolated hill called the Hill of Mercy, a little way outside the holy territory, on the road from Mecca to Táif. One leaving Mecca after midday can easily reach the place on foot the same evening. The road is first northwards along the Mecca valley and then turns eastward. It leads through the straggling village of Mináa, occupying a long narrow valley (W. Miná), two to three hours from Mecca, and thence by the mosque of Muzdalifa over a narrow pass opening out into the plain of 'Arafa, which is an expansion of the great W. Nu'mán, through which the Táif road descends from Mount Kara. The lofty and rugged mountains of the Hodheyl tower over the plain on the north side and overshadow the little Hill of Mercy, which is one of those bosses of weathered granite so common in the Ḥijáz. 'Arafa, as we have already seen, lay quite near Dhu'l-Majáz, where, according to Arabian tradition, a great fair was held from the 1st to the 8th of the pilgrimage month; and the ceremonies from which the ḥajj was derived were originally an appendix to this fair. Now on the contrary the pilgrim is expected to follow as closely as may be the movements of the Prophet at his "farewell pilgrimage" in the year 10 of the Flight (632 A.D.). He therefore leaves Mecca in pilgrim garb on the 8th of Dhu'l Ḥuja, called the day of tarwíya (an obscure and pre-Islamic name), and strictly speaking should spend the night at Miná. It is now, however, customary to go right on and encamp at once at 'Arafa. The night should be spent in devotion, but the coffee booths do a lively trade, and songs are as common as prayers. Next forenoon the pilgrim is free to move about, and towards midday he may if he please hear a sermon. In the afternoon the essential ceremony begins; it consists simply in "standing" on 'Arafa shouting Labbeyka and reciting prayers and texts till sunset. After the sun is down the vast assemblage breaks up, and a rush (technically *ifáḍa*, *daf'*, *nafr*) is made in the utmost confusion to Muzdalifa, where the night prayer is said and the night spent. Before sunrise next morning (the 10th) a second "stand" like that on 'Arafa is made for a short time by torchlight round the mosque of Muzdalifa, but before the sun is fairly up all must be in motion in the second *ifáḍa* towards Miná. The day thus commenced is the "day of sacrifice," and has four ceremonies—(1) to pelt with seven stones a cairn (*jamrat el 'aḳaba*) at the eastern end of W. Miná, (2) to slay a victim at Miná and hold a sacrificial meal, part of the flesh being also dried and so preserved, or given to the poor,[3] (3) to be shaved and so terminate the *iḥrám*, (4) to make the third *ifáḍa*, *i.e.*, go to Mecca and perform the ṭawáf and sa'y (*'omrat el-ifáḍa*), returning thereafter to Miná. The sacrifice and visit to Mecca may, however, be delayed till the 11th, 12th, or 13th. These are the days of Miná, a fair and a joyous feast, with no special ceremony except that each day the pilgrim is expected to throw seven stones at the *jamrat el 'aḳaba*, and also at each of two similar cairns in the valley. The stones are thrown in the name of Alláh, and are generally thought to be directed at the devil. This is, however, a custom older than Islám, and a tradition in Azraḳí, p. 412, represents it as an act of worship to idols at Miná. As the stones are thrown on the days of the fair, it is not unlikely that they have something to do with the old Arab mode of closing a sale by the purchaser throwing a stone (Bírúní, p. 328).[4] The pilgrims leave Miná on the 12th or 13th, and the ḥajj is then over.

The colourless character of these ceremonies is plainly due to the fact that they are nothing more than expurgated heathen rites. In Islám proper they have no *raison d'être*; the legends about Adam and Eve on 'Arafa, about Abraham's sacrifice of the ram at Thabír by Miná, imitated in the sacrifices of the pilgrimage, are mere clumsy afterthoughts, as appears from their variations and only partial acceptance. It is not so easy to get at the nature of the original rites, which Islám was careful to suppress. But old usages were not quickly eradicated, and we find mention of practices condemned by the orthodox, or forming no part of the Moslem ritual, which may be regarded as traces of an older ceremonial. Such are nocturnal illuminations at Miná (Ibn Baṭúṭa, i. 396), 'Arafa, and Muzdalifa (Ibn Jubair, p. 179), and ṭawáfs performed by the ignorant at holy spots at 'Arafa not recognized by law (Snouck-Hurgronje, p. 149 *sq.*). We know that the rites at Muzdalifa were originally connected with a holy hill bearing the name of the god Ḳuzaḥ (the Edomite Kozé) whose bow is the rainbow, and there is reason to think that the *ifáḍas* from 'Arafa and Ḳuzaḥ, which were not made as now after sunset and before sunrise, but when the sun rested on the tops of the mountains, were ceremonies of farewell and salutation to the sun-god.

The statistics of the pilgrimage cannot be given with certainty and vary much from year to year. The quarantine office keeps a record of arrivals by sea at Jiddah (30,271 for the year 1878 A.D., or 1295 A.H.); but to these must be added the great overland caravans from Cairo, Damascus, and 'Irak, the pilgrims who reach Medina from Yanbu' and go on to Mecca, and those from all parts of the peninsula. Burckhardt in 1814 estimated the crowd at 'Arafa at 70,000, Burton in 1853 at 50,000, 'Abd el-Razzáḳ in 1858 at 60,000. This great assemblage is always a dangerous centre of infection, and the days of Miná especially, spent under circumstances originally adapted only for a Bedouin fair, with no provisions for proper cleanliness, and with the air full of the smell of putrefying offal and flesh drying in the sun, produce much sickness.

*Literature.*—Besides the Arabic geographers and cosmographers, many of whom have been already cited, we have Ibn 'Abd Rabbih's description of the mosque, early in the 10th century (*'Iḳd Farid*, Cairo edition, iii. 362 *sq.*), but above all the admirable record of Ibn Jubair (1184 A.D.), by far the best account extant of Mecca and the pilgrimage. It has been much pillaged by Ibn Baṭúṭa. The Arabic historians are largely occupied with fabulous matter as to Mecca before Islam; for these legends the reader may refer to C. de Perceval's *Essai*. How little confidence can be placed in the pre-Islamic history appears very clearly from the distorted accounts of Abraha's excursion against the Ḥijáz, which fell but a few years before the birth of the Prophet, and is the first event in Meccan history which has confirmation from other sources. See Nöldeke's version of Ṭabarí, p. 204 *sq.* For the period of the Prophet Ibn Hishám and Wáḳidí are valuable sources in topography as well as history. Of the special histories and descriptions of Mecca published by Wüstenfeld (*Chroniken der Stadt Mekka*, 3 vols., 1857–59, with an abstract in German 1861), the most valuable is that of Azraḳí. It has passed through the hands of several editors, but the oldest part goes back to the beginning of the 9th Christian century. Ḳuṭb el-Dín's history (vol. iii. of the *Chroniken*) goes down with the additions of his nephew to 1592 A.D.

Of European descriptions of Mecca from personal observation the best is Burckhardt's *Travels in Arabia* (cited above from the 8vo ed., 1829). *The Travels of Aly Bey* (Badia), London, 1816, describe a visit in 1807; Burton's *Pilgrimage* (3d ed., 1879) often supplements Burckhardt; Von Maltzan's *Wallfahrt nach Mekka*, 1865, is lively but very slight. 'Abd el-Razzáḳ's report to the Government of India on the pilgrimage of 1858 is specially directed to sanitary questions. For the pilgrimage see particularly Snouck-Hurgronje, *Het Mekkaansche Feest*, Leyden, 1880. (W. R. S.)

[1] The latter perhaps was no part of the ancient 'omra; see Snouck-Hurgronje, *Het Mekkaansche Feest*, 1880, p. 115 *sq.*

[2] The 27th was also a great day, but this day was in commemoration of the rebuilding of the Ka'ba by Ibn Zubeyr.

[3] The sacrifice is not indispensable except for those who can afford it and are combining the ḥajj with the 'omra.

[4] On the similar pelting of the supposed graves of Abú Lahab and his wife (Ibn Jubair, p. 110) and of Abú Righál at Mughammas, see Nöldeke's translation of Ṭabarí, p. 203.

# MECHANICS

STRICTLY speaking, the derivation of this word should have prevented the use of it as the designation of a pure science. It has been, however, employed for a long period in English speech in the identical sense that the French attach to *Mécanique pure* or the Germans to *Reine Mechanik*. These terms are all employed to denote what we should much prefer to call *Abstract Dynamics*,—the pure science which (as the derivation implies) treats of the action of Force upon Matter, but which is, correctly, the *Science of Matter and Motion*, or *of Matter and Energy*.

With the view of making clear from the outset the reason for the arrangement adopted in this article, we commence by stating in Newton's own words (accompanied by a paraphrase) the *Axiomata, sive Leges Motus*, which form the entire basis of our subject. These laws will at once indicate the order in which the subject may most logically be treated. We defer to the end of the article the more close consideration of the idea introduced by the word "force," as well as general remarks on "energy," &c. For the present we are content to regard force as defined for us by Newton's Laws.

*Newton's Laws of Motion.*

Newton's first law. § 1. Lex I. Corpus omne perseverare in statu suo quiescendi vel movendi uniformiter in directum, nisi quatenus illud a viribus impressis cogitur statum suum mutare.

*Every body continues in its state of rest, or of uniform motion in a straight line, except in so far as it is compelled by force to change that state.*

Second law. Lex II. Mutationem motus proportionalem esse vi motrici impressæ, et fieri secundum lineam rectam qua vis illa imprimitur.

*Change of (quantity of) motion is proportional to force, and takes place in the straight line in which the force acts.*

Third law. Lex III. Actioni contrariam semper et æqualem esse reactionem; sive corporum duorum actiones in se mutuo semper esse æquales et in partes contrarias dirigi.

*To every action there is always an equal and contrary reaction; or the mutual actions of any two bodies are always equal and oppositely directed.*

Scholium. § 2. In 1863 Thomson and Tait (upon whose *Treatise on Natural Philosophy* much of what follows is based) called attention to the fact that, as regards Lex III., Newton gives in a scholium a second sense in which the words may be interpreted. In the first sense the action and reaction are mere forces, in the second they are *the rates at which forces do work*. Hence, and for another reason which will appear later, the word "activity" has been introduced as the English equivalent of the word *actio* in Newton's second sense. Here is the passage:—

Si æstimetur agentis actio ex ejus vi et velocitate conjunctim; et similiter resistentis reactio æstimetur conjunctim ex ejus partium singularum velocitatibus et viribus resistendi ab earum attritione, cohæsione, pondere, et acceleratione oriundis; erunt actio et reactio, in omni instrumentorum usu, sibi invicem semper æquales.

*If the activity of an agent be measured by its amount and its velocity conjointly; and if, similarly, the counter-activity of the resistance be measured by the velocities of its several parts and their several amounts conjointly, whether these arise from friction, molecular forces, weight, or acceleration; —activity and counter-activity, in all combinations of machines, will be equal and opposite.*

This may be looked upon as a Fourth Law. But, in strict logic, the First Law is superfluous, because its consequences are all implied (by negation) in the statement of the Second. (See § 8 below.) Hence there are, virtually, only three laws, so far as Newton's system is concerned.

Basis of Newton's laws. § 3. These laws are to be considered as deductions from observation and experiment, and in no sense as having an *a priori* foundation. Their proof, so far as rigorous proof is attainable in physical matters, is commonly looked on as being furnished in the most conclusive form by observational astronomy. The *Nautical Almanac*, published usually about four years in advance, contains the predicted places of the sun, moon, and principal planets from day to day, in some cases from hour to hour, throughout the year. The predictions are entirely based upon the laws of motion (along with the law of gravitation), and could not possibly be accurate unless these laws are true. So thoroughly satisfactory has hitherto been the coincidence between prediction and observation that, when a deviation occurs, no one dreams of a defect in the principles of the reasoning. On the contrary, such deviations are utilized for the purpose of correcting our knowledge of the "elements" of the orbits of the moon and planets, or our estimates of the masses of these bodies; and, as in the brilliant investigations of Adams and Leverrier, they sometimes enable us to discover the existence and even assign the position of a planet never before seen.

Newton's predecessors. § 4. It is not clear in what order, or by whom, these laws were first discovered. Galileo was undoubtedly acquainted with the first two; and Huygens, Wren, Hooke, and others were acquainted with the Third Law in some of its many applications. But they were first systematized and, as we have seen, extended in a most important manner by Newton. Though they were sadly disfigured in Britain during the fifty years which elapsed after the revival of mathematics in the early part of this century, they have of late been restored to the form in which Newton gave them. This readoption of Newton's simple but comprehensive system has of itself aided in no small degree the recent rapid advance of science.

Anthropomorphisms. One peculiarity of Newton's language must be noticed here, though very briefly, as we will return to the subject towards the end of the article. A force is said to "compel" a change of state in a body; bodies are said mutually to "act" on one another, &c. Such language is, of course, in its literal acceptation, of an anthropomorphic character; but, if one thinks of the habitual use even in scientific books of such expressions as "the sun rises," "the wind blows," &c., it cannot be construed into an assertion that force has real objective existence.

*Comments on the Laws of Motion.*

Definition of force. § 5. Law I. First of all this law tells us what happens to a piece of matter which is left to itself, *i.e.*, not acted on by forces. It preserves its "state," whether of rest or of uniform motion in a straight line. This property (which, as we shall presently show, § 7, is considerably extended by Newton himself) is commonly called the "inertia" of matter, in virtue of which it is incapable of varying in any way its state of rest or motion. It may be the sport of forces for any length of time, but so soon as they cease to act it remains in the state in which it was left until they recommence their action on it. Hence, whenever we find the state of a piece of matter changing, we conclude that it is under the action of a force or forces. Thus, for the present, we have the definition of "force" as part of this First Law:—

Inertia.

*Force is whatever changes the state of rest or uniform motion of a body.*

When a body, originally at rest, begins to move, we conclude that force is acting on it. And when a moving body is seen to change *either* the speed *or* the direction of its motion, we conclude that this is due to force.[1]

Absolute and relative.

§ 6. But there is much more than this, even in the First Law. What is "rest"? The answer must be that the term is relative. Absolute rest and absolute motion are terms to which we find it impossible to assign a meaning. Maxwell has well said (in his *Matter and Motion*):—

"All our knowledge, both of time and place, is essentially relative. When a man has acquired the habit of putting words together, without troubling himself to form the thoughts which ought to correspond to them, it is easy for him to frame an antithesis between this relative knowledge and a so-called absolute knowledge, and to point out our ignorance of the absolute position of a point as an instance of the limitation of our faculties. Any one, however, who will try to imagine the state of a mind conscious of knowing the absolute position of a point will ever after be content with our relative knowledge."

As will be seen later, the First Law gives us also a physical definition of "time," and physical modes of measuring it.

Newton's comments on the first law.

§ 7. Newton's own comment on this law is as follows:—

Projectilia perseverant in motibus suis, nisi quatenus a resistentia aeris retardantur, et vi gravitatis impelluntur deorsum. Trochus, cujus partes cohærendo perpetuo retrahunt sese a motibus rectilineis, non cessat rotari, nisi quatenus ab aere retardatur. Majora autem planetarum et cometarum corpora motus suos et progressivos et circulares, in spatiis minus resistentibus factos, conservant diutius

It is particularly worthy of notice that we have here the undisturbed rotation of a body about an axis introduced as another of those "states" in which it will continue, in virtue of the First Law, until force acts to compel it to change that state. Also it is to be noticed that Newton adduces a hoop, whose axis is fixed in direction both in the body and in space, as an example of this new form of state maintained in virtue of inertia. Later, it will be seen that the same thing is true of a body free in space and rotating about the principal axis of greatest or of least moment of inertia through its centre of mass.[2]

Consequences of second law.

§ 8. Law II. What Newton designates by the word *motus* is, as he has clearly pointed out, the same as is expressed by *quantitas motus*, that for which we now usually employ the term "momentum." Its numerical value depends not only on the rate of motion, but also on the amount of matter, or "mass," of the moving body, and is directly proportional to either of these when the other is unaltered. But it is regarded by Newton as having direction as well as magnitude. It is, in fact, what in the language of quaternions is called a "vector." The change of such a quantity may be either in numerical magnitude, or in direction, alone, or simultaneously in both. We now see what this Second Law enables us to do. For

(*a*) Given the mass of a body, the force acting on it, and the time during which it acts, we can calculate the change of motion. This is the *direct* problem of dynamics of a particle.

(*b*) Given the mass, and the change of velocity, we can calculate the magnitude and direction of the force acting. This is the *inverse* problem.

(*c*) We can compare, and so measure, forces by the changes of motion they produce in one and the same body.

(*d*) We can compare the masses of different bodies by finding what changes of velocity one and the same force produces in them.

(*e*) We can find the *one* force which is equivalent, in its action, to any given set of forces. For, however many changes of motion may be produced by the separate forces, they must obviously be capable of being compounded into a single change, and we can calculate what force would produce that.[3]

Necessity for a third law

§ 9. Hitherto, we have spoken of *the* motion of a body,—thus implying (except, of course, in the case of Newton's hoop or that of the earth) that all its parts are moving in exactly the same way. From this point of view every body, however large, may be treated as if it were a single particle. But when the parts of a body have different velocities, as when a rigid body is rotating, or as when a non-rigid body is suffering a change of form, the question becomes much more complex. We cannot at this stage enter into a full explanation, but will take a couple of very simple cases to show the nature of the new difficulties, and thence the necessity for an additional law.

Suppose a bullet to be thrown in any direction. If we know with what force the earth attracts it, the calculation of the path it will pursue depends on the Second Law, which gives all the necessary preliminary information. But let two bullets be tied together by a string: we know by trial that each moves, in general, in a manner very different from that in which it would move if free. The path of each is now, usually, a tortuous curve, while its free path would be plane. It is no longer subject to gravity alone but also to what is called the "tension" of the string. If we knew the amount of this tension on either of the bullets and its direction, we could calculate, by the help of the Second Law alone, all the circumstances of the motion of that bullet. But how are we to find this tension? Is it even the same for each bullet? This, if answered in the affirmative, would simplify matters considerably, but we should still require to know the amount and direction of the tension. It is clear that, without a further axiom, we cannot advance to a solution of the question.

Consequences of third law.

§ 10. Law III. Furnished with this, in addition to our previous information, we can attack the question with more hope. We see by this law that, whatever force be exerted by the string on one of the bullets, an equal and opposite force, which must therefore be in the direction of the string, is exerted on the other. Still, the magnitude of these equal forces remains to be found. But the string in no way interferes with the motion of either bullet *unless it is tight, i.e.*, unless the distance between the bullets is equal to the length of the string. Hence, whenever the unknown force comes into play, at the same time there comes in a geometrical relation of relative position between the two bullets. *This supplies the additional equation necessary for the determination of the new unknown quantity.*

Rigid constraint.

Variable constraint.

§ 11. As an additional illustration, suppose the string to be made of india-rubber. The Third Law tells us that the tensions it exerts on the bullets are still equal and opposite. But we no longer have the geometrical condition we had before. We have, however, what is quite sufficient, a

[1] The words we have italicized will be seen to have very important bearings on certain old errors which even now crop up, and which have introduced one of the most inappropriate and apparently ineradicable of terms ("centrifugal force") into the usual vocabulary of our subject.

[2] It is also, in a partial sense, true of a free body of which two principal axes through the centre of mass have equal moments of inertia. In that case, as we will show later, even when couples act upon the body, provided they be in planes passing through the third axis, the rate of rotation about that axis remains unaltered, *though its direction in space changes.* This is approximately the case of the earth. The attractions of the sun and moon on the protuberant parts about the equator produce "precession" and "nutation," but do not influence the length of the day.

[3] It is to be observed here that Newton's silence is as expressive as his speech. When he says "change of motion" we understand that it does not matter what the original motion was; and, when he mentions only one force, he implies that the effect of any one force is the same whether others are also at work or not. In fact, with Newton there can be no balancing of forces, though there may be balancing of the effects of forces, a very different thing.

knowledge of *how the tension of the string depends on its length*. Thus the tension can be calculated from the relative position of the bullets.

Transference of energy.

§ 12. Scholium to Law III. On this we will, for the present, remark only that it furnishes us with the means of studying directly the transference of energy from one body or system to another. Experiment, however, was required to complete the application of this part of Newton's systematic treatment of the subject. What was wanted, and how it has been obtained, will be treated of later. The first words of the scholium, however, claim for Newton the discovery of the clause we have extracted from it. For they run thus :—Hactenus principia tradidi a mathematicis recepta, et experientia multiplici confirmata.

Division of the subject.

§ 13. What has now been said enables us to see the order in which the fundamental ideas should be taken up, so that the necessities of each should be provided for before its turn comes. An indispensable preliminary is the study of motion in the abstract, *i.e.*, without any reference to *what is moving*. This is demanded in order that we may be able to apply the Second Law. The science of pure motion, without reference to matter or force, is an extension of geometry by the introduction of the idea of time and the consequent idea of velocity. Ampère suggested for it the term *Cinematique*, or, as we shall write it, *Kinematics*. We include under it all changes of form and grouping which can occur in geometrical figures or in groups of points.

We shall then be prepared to deal with the action of force on a single particle of matter, or on a body which may be treated as if it were a mere particle. Thus we have the Dynamics of a Particle. This, again, splits into two heads, Statics and Kinetics of a Particle. But all this requires the Second Law only. When we have two or more connected particles, or two particles attracting one another or impinging on one another, the Third Law is required. Next in order of simplicity come the Statics and Kinetics of a Rigid Solid. Then we have to deal with bodies whose form, &c., are altered by forces—flexible bodies, elastic solids, fluids, &c. Finally, we must briefly consider the general principles, such as "conservation of energy," "least action," &c., which are deducible by proper mathematical methods from Newton's Laws, and of which some at least, if we could more clearly realize their intrinsic nature, would probably be found to express even more simply than do Newton's Laws the true fundamental principles of abstract dynamics.

We will not restrict ourselves to one uniform course in the application of mathematical methods. Rather, as considerations of space require to be attended to, we will vary our methods from one part of the subject to another, so as to exhibit, each at least once, all the more usual processes. And we will endeavour to make the large-type portions of the article, in which only the most elementary mathematics will be introduced, a self-contained treatise which may be read by students of very moderate mathematical knowledge.

## KINEMATICS.

### *Position and the Means of Assigning it.*

Position.

§ 14. Motion (or displacement) consists simply in "change of position." Hence, to describe motion, we must have the means of assigning position. This is, of course, a question of GEOMETRY (*q.v.*). See also QUATERNIONS.

From these articles it appears that the position of one free point with reference to another (all these space relations are relative, as we have already said) depends on *three numbers*, of which one at least must involve the unit of length. In Cartesian rectangular coordinates, we denote these by $x$, $y$, $z$, which indicate respectively the distance of the point from each of three planes at right angles to each other, and all passing through the origin (or reference point). From another point of view they may be called "degrees of freedom." When the value of one is assigned, say by

Degrees of freedom.

$$x = a,$$

the point is said to have lost one degree of freedom, or to have had imposed upon it one "degree of constraint." It must now lie in a plane parallel to the first of the reference planes, and at a distance $a$ from it. When a second degree of constraint is applied, say by

of constraint.

$$y = b,$$

another degree of freedom is lost. The point's position is limited to lie in a second plane in a given position at right angles to the first. It must therefore lie somewhere on the straight line which consists of the series of points common to the two planes. A third degree of constraint

$$z = c$$

takes away its one remaining degree of freedom; and its position is now definitely assigned as the single point of intersection of three given planes.

§ 15. But constraint may be applied in other ways. Thus if we assign the condition

$$x^2 + y^2 + z^2 = a^2,$$

we deprive the point of one degree of freedom by compelling it to remain at a distance $a$ from the origin. It is now limited to the surface of a sphere, but its latitude and longitude on that sphere may be any whatever. Here again the imposition of one degree of constraint has taken away one degree of freedom.

§ 16. In general, one degree of constraint may be expressed as

Examples of constraint.

$$f(x, y, z) = \xi.$$

This, when $\xi$ has an assigned value, is the equation of a definite surface on which the point must lie. Three such conditions determine the position of the point, and may therefore be looked upon as introducing $\xi$, $\eta$, $\zeta$, another set of coordinates, which may be used in place of $x, y, z$. The number of such systems is, of course, unlimited; but it is often possible to choose one in which the conditions of a problem are much more simply expressed than they were when expressed in $x, y, z$. The whole question belongs to what is called "change of variables." To give an elementary instance of its use,—suppose we take the ordinary simple pendulum, a pellet supported by a fine thread or wire, and oscillating in a vertical plane. If the origin be placed at the point of suspension, and the axis of $z$ be vertical, we have two conditions :—

$$x^2 + y^2 + z^2 = a^2,$$

where $a$ is the length of the thread; and

$$y/x = \tan \alpha,$$

where $\alpha$ denotes the azimuth of the plane of oscillation. There is but one degree of freedom left, because two degrees of constraint have been imposed. We may choose for this either $x$, $y$, or $z$; But we should in each case be led to complex expressions. If, however, we consider that all the freedom left to the pendulum is to oscillate in a given plane, we may denote its sole remaining degree of freedom by $\theta$, the angle which the string makes with the vertical; and form our dynamical equation in terms of this. When $\theta$ is found by dynamical considerations, we have

$$x = a \sin\theta \cos\alpha, \quad y = a \sin\theta \sin\alpha, \quad z = a \cos\theta.$$

Here $\theta$ comes in as what is called a "generalized coordinate."

Generalized coordinates.

If the pendulum be not limited to one plane, the azimuth, as well as the angle, of the displacement from the vertical may be any whatever. Hence there are two degrees of freedom, which are indicated by the generalized coordinates $\alpha$ and $\theta$.

§ 17. In general, in any system originally with any number $m$ of degrees of freedom, and subjected to a number $n$ of degrees of constraint, the whole motion can be fully characterized by $m-n$ independent quantities, called generalized coordinates, and corresponding to the degrees of freedom which remain. The elegance and simplicity of a solution often depend in a marked manner upon the choice of these; and the transformation of the general equations from Cartesian to generalized coordinates forms one of the most powerful and elegant contributions to abstract dynamics which Lagrange made in the *Mécanique Analytique*.

Freedom of a rigid system.

§ 18. A rigid system has only *six* degrees of freedom:—three translations for any one of its points, and three independent rotations about axes passing through that point.

When one point is fixed, it loses the three translations, and has only three degrees of freedom. When a second point is fixed, it loses other two; in fact it can no longer move except by turning round the line joining the fixed points. When a third point, not in line with the other two, is fixed, there is no degree of freedom left; the system is fixed.

Linear relations among small displacements.

§ 19. It may be well to notice here that, in all cases which we shall require to consider, whatever be the relations among two different sets of variables which we employ alternatively to determine the relative positions of the parts of any system, the equations which give the relations between corresponding small increments of these variables are always *linear* so far as these increments are concerned. Thus, for instance, if we have as above a condition of the form

$$f(x, y, z) = \xi,$$

we deduce from it at once

$$\left(\frac{df}{dx}\right)\delta x + \left(\frac{df}{dy}\right)\delta y + \left(\frac{df}{dz}\right)\delta z = \delta\xi,$$

Here the differential coefficients are partial.

In such cases, any homogeneous function of the second order in $\delta x$, $\delta y$, $\delta z$, &c., will be represented by a homogeneous function, also of the second order, in $\delta\xi$, $\delta\eta$, &c., however many be the coordinates in the separate systems. When, however, one or more of the equations of condition involves the element of *time* explicitly, the relations among corresponding small increments of the alternative sets of coordinates, though still linear, will not be *homogeneous*. Thus a homogeneous function of the second order in one set will be a function of the second order in the other set, but not homogeneous, unless the increments are produced instantaneously.

To give a single instance, suppose that the string of a simple pendulum (not necessarily oscillating in one plane) *contracts* uniformly. We shall now have

$$x^2 + y^2 + z^2 = (a - et)^2$$

instead of the equation in the example § 15, and one of our equations among increments is

$$x\delta x + y\delta y + z\delta z = -e(a - et)\delta t,$$

which, though still linear, is no longer homogeneous in the increments of *coordinates*.

## *Kinematics of a Point.*

Continuity of path of point.

§ 20. The one necessary characteristic of the path described by a moving point is its *continuity*. There can be no break or gap in it. But, as we study kinematics, at present, solely for its physical applications, we impose a restriction on such complete generality. The path of a moving *particle* must be one of *continuous curvature*, unless either (1) the motion ceases and commences again in a different direction (in which case we have two separate and successive states of motion to consider), or (2) an infinite force is applied to the particle (a case which we need not consider). A similar remark, we may say in passing, applies to velocity also. So that, for our purpose, we may confine ourselves to the geometrical properties of the motion of a point whose rate and direction of motion change continuously, if at all, and not by fits and starts.

Direction of motion.

§ 21. If the point describe a straight line, that line gives the direction of its motion at every instant. If it describe a curve, the direction of its motion is at every instant that of the corresponding tangent to the curve.

Change of direction.

Let A, B, C, D represent four points on the path taken in close succession, in the order in which the moving point reaches them. From A the point moves to B, so that the line joining A and B (the tangent) is the direction of motion at A. Similarly the line joining B and C gives the direction of motion at B. The points A, B, C of course lie in one plane. This is the plane in which, for two successive elements of its path, the point is moving. It is therefore that in which the change of direction of motion takes place, and is called the "osculating plane." And, just as the straight line through A and B gives the direction of motion at A, so the circle passing through the points A, B, C determines the "curvature" of the path at A. If we apply the same reasoning to the three successive points B, C, D, we see the difference between a "plane" and a "tortuous" curve. For, if D lie in the plane ABC, the osculating plane is the same at A and at B; and if the same holds for other successive points the whole bending takes place in one plane. But if D be not in the plane ABC, BCD is the osculating plane at B, and we thus see that successive positions of the osculating plane of a tortuous curve are produced by its rotation about the tangent BC to the path; for BC is in both planes ABC and BCD. We shall not have space here to deal in detail with cases of tortuosity; but it was necessary to point out their essential nature.

Osculating plane.

Tortuous path.

Curvature.

§ 22. The curvature of ABC obviously depends upon the change of direction from AB to BC, and is directly proportional to it. But it is obviously greater, for the same amount of change of direction, as ABC is less. In a circle the curvature is the same at all points, and, as the radius is everywhere perpendicular to the tangent, the change of its direction is the same as that of the tangent. Hence the curvature, being the change of direction *per unit length of the arc*, is measured simply by the reciprocal of the radius.

Generally, if $\phi$ be the angle between the tangent at A and any fixed line in the osculating plane, and if $s$ represent the length of the curve measured from any fixed point on it to A, we have, by the fundamental property of infinitesimals,

$$\mathrm{L}\frac{\delta\phi}{\delta s} = \frac{d\phi}{ds} = \text{curvature},$$

(We will use, as above, the letter L for a limit, in the sense in which that term was introduced by Newton.)

In a circle we have always ($a$ being the radius)

$$s = a\phi,$$

and hence the curvature

$$\frac{d\phi}{ds} = \frac{1}{a};$$

so that in general the measure of curvature is the reciprocal of the radius of the circle passing through three consecutive points of the path. For other analytical expressions for curvature see vol. xiii. p. 26.

For a curve in space (whether tortuous or not) we have

$$\text{Curvature} = \frac{1}{\rho} = \sqrt{\left(\frac{d^2x}{ds^2}\right)^2 + \left(\frac{d^2y}{ds^2}\right)^2 + \left(\frac{d^2z}{ds^2}\right)^2},$$

while the direction cosines of the radius of curvature are

$$\rho\frac{d^2x}{ds^2}, \quad \rho\frac{d^2y}{ds^2}, \quad \rho\frac{d^2z}{ds^2}.$$

Evolute and involute.

§ 23. The chief properties connected with the curvature of a plane curve are made very clear by the artifice of regarding it as an "involute." This idea introduces us to the kinematics of a flexible and inextensible line. Suppose such a line, held tight, to be wrapped round a cylinder of any form, in a plane perpendicular to its axis, each point of it, when it is unwound in its own plane, will describe a curve whose form depends upon that of the transverse section of the cylinder. Let $P_0M'M$ (fig. 1) be such a section of the cylinder; MP, M'P', two positions of the free part of the cord; P, P', the corresponding positions of

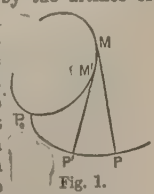


Fig. 1.

a definite point of the cord; $PP'P_0$ the path described by that point. Then $PP'P_0$ is one of the involutes of $MM'P_0$; the others are the curves traced by other points of the string. But, with reference to $PP'P_0$, the curve $MM'P_0$ is *the* "evolute." The evolute of such a curve is, in fact, unique; for it is obvious that the line MP, in any of its positions, is revolving about the point of contact M with the evolute; so that P describes an infinitesimal arc of a circle of which M is the centre. Thus the evolute of a plane curve is the locus of its centre of curvature. And it is clear from the genesis of the involute that

$$PM = P'M + M'M = P_0M'M.$$

For the analytical discussion of evolutes, see vol. xiii. p. 26.

The subject of evolutes is of importance in various branches of physics, especially in optics. In mechanics its chief use is connected with the theory of the pendulum, as it shows how to cause the bob to move in a cycloid, the only path in which the time of oscillation is the same whatever be the extent of the oscillations.

Speed. § 24. When the line, curved or straight, in which the motion takes place is given, the position of the moving point is at once assigned in terms of a single numerical quantity. In fact it has only one degree of freedom, and its position is known by the length of the arc of the curve from any fixed point to the given position. In such a case as this we are not concerned with the direction of the motion, for that is already assigned at every point of the path. We are concerned only with what we may call the "speed" of the motion. (We purposely avoid the use of the term "velocity" here, because it properly includes direction as well as speed, as will be seen later.)

Average speed. § 25. Suppose an observer to be watching the motion (as, for instance, a traveller by rail notes the telegraph posts which he passes, referring at each to his watch), and to find that at any time $t_1$ the moving point was at $s_1$, while at time $t_2$ it was at $s_2$.

Then it is clear that the *average* speed during this part of the motion is to be found by dividing the number of units of space passed over by the number of units of time employed. For it must be greater as the former is greater and less as the latter is greater. Hence the average speed is $\frac{s_2 - s_1}{t_2 - t_1}$.

Measurement of uniform and of variable speed. If the speed has been *uniform* during the motion observed, this average value has coincided with the actual value all through; and, if the measures of space and time are accurate, we shall get exactly the same value of this ratio whether the interval of time is small or large. Hence, if $v$ be the speed of a uniformly moving point, the space it describes in time $t$ is $vt$. But if the speed has been *variable*, it must at some parts of the interval have been greater, at others less, than this average. And the shorter we take the interval the less will be the difference between the greatest and least speeds during its lapse, so that the average speed will coincide more and more nearly with the actual speed. In the language of "fluxions" (which was invented for the sake of this subject) the measure of the speed at any time $t_1$ is

$$\dot{s} = \mathrm{L}\frac{s_2 - s_1}{t_2 - t_1},$$

when the interval $t_2 - t_1$ is shortened indefinitely. The accuracy of the preceding process depends entirely upon the limitations we have introduced for the purpose of confining ourselves to cases which can occur in ordinary physical problems. For the general reasoning on which it is based is obviously inapplicable to cases in which the speed alters by jerks—at least during the interval considered, small as it may be. But we are fortunately not required to discuss here the very delicate questions to which this may give rise. Considerable difficulty is sometimes felt by a student when he is told that at a certain part of its course a point has a speed say of 10 miles an hour, while the whole course may be only a few inches. But this arises from the novelty of the conception. It is not meant, when we speak of a speed of 10 miles per hour, that the motion necessarily lasts for an hour, or even for a second, but only that, *if the then speed were to be maintained constant for an hour, the moving point's path, of whatever form, would be exactly* 10 *miles long.* In actual experience in a railway train we can judge the speed (roughly at least), and we find nothing strange in saying "Now we are going at twenty miles an hour," "Now at six," and so on. And it is clear that, after the steam is put on, the train, however short its run, must go through all rates of speed from zero to its maximum, and then through all of them to zero again, when the steam is cut off and the brake applied.

In the language of the differential calculus this becomes

$$\dot{s} = \mathrm{L}\frac{\delta s}{\delta t} = \frac{ds}{dt}$$

The fluxional notation of Newton, in which the dot over a quantity expresses the rate of its increase, *i.e.*, its differential coefficient with regard to time considered as the independent variable, is still very convenient in abstract dynamics, and is, in fact, indispensable when we come to the higher generalizations. We shall, therefore, freely employ it when it is specially useful.

Dimensions of speed. § 26. Whether uniform or variable, speed depends for its numerical value upon the units chosen for linear space and for time. Its dimensions are $[LT^{-1}]$, and consequently, its numerical expression is increased in proportion as the unit of time is increased, and diminished in proportion as that of length is increased. Thus the speed represented by 10 in feet per second becomes

$$\frac{3600}{5280} \cdot 10 = \frac{75}{11}$$

when expressed in miles per hour.

Rate of change of speed. § 27. The rate at which the speed (when not uniform) changes is found by a process precisely similar to that employed for the speed itself. Let the speed

at time $t_1$ be observed to be $v_1$,
" $t_2$ " " $v_2$;

then the average rate of increase of speed during the interval is

$$\frac{v_2 - v_1}{t_2 - t_1}.$$

The dimensions of this quantity are obviously $[LT^{-2}]$. Thus its numerical value is diminished, like that of speed, in proportion as the unit of length is increased. But it is increased in the duplicate of the proportion in which the unit of time is increased. For instance a rate of increase of speed of 32·2 feet per second per second (the mere *statement* is enough to show the double dependence on the time unit) becomes

$$32{\cdot}2\frac{(3600)^2}{5280} = 79{,}036 \text{ nearly},$$

when expressed in terms of miles and hours.

Uniform change of speed. § 28. When the rate of increase of speed is uniform, the above average value is its actual value throughout the interval. Hence with uniform rate of increase $= \alpha$, a speed V becomes in time $t$

$$v = \mathrm{V} + \alpha t.$$

Also, as it increases uniformly, its average value during time $t$ is half way between its values at the beginning and end of that time; *i.e.*, it is

$$\mathrm{V} + \tfrac{1}{2}\alpha t.$$

The space described during the interval is at once found (§ 25) as the product of the interval and the average speed during its lapse;—*i.e.*, it is

$$s = \mathrm{V}t + \tfrac{1}{2}\alpha t^2.$$

And it is easy to see from these expressions that

$$v^2 = V^2 + 2as,$$

which gives the speed acquired in terms of the space traversed.

§ 29. This is the only case in which the result can be reached without formally using the methods of the integral calculus. These expressions enable us at once to solve a great number of simple questions connected with the motion of a stone or bullet, under the action of gravity, in a vertical line. For it is found by experiment that gravity impresses, in every second, a downward speed of 32·2 feet per second on an unsupported body; and, by the Second Law, this is independent of the body's previous motion.

Hence, if a stone be let fall, its speed after $t$ seconds is $32{\cdot}2t$, and the space fallen through is $16{\cdot}1t^2$. Also, if it fall through $s$ feet, it will acquire a speed whose square is $v^2 = 64{\cdot}4s$.

Again, if a stone be thrown upwards with a speed of 300 feet per second, after $t$ seconds its speed will be $300 - 32{\cdot}2t$, and the height to which it has then ascended is $300t - 16{\cdot}1t^2$. Thus it stops, and turns, after $\frac{300}{32{\cdot}2}$ seconds; and the greatest height it reaches is $\frac{300^2}{64{\cdot}4}$ feet.

From the statement above, putting $\dot{s} = v$, we find

$$\ddot{s} = \dot{v} = \mathrm{L}\frac{v_2 - v_1}{t_2 - t_1} = \frac{dv}{dt}.$$

From this expression the preceding results may be at once obtained. Thus, assuming

$$\ddot{s} = a,$$

we have by integration

$$\dot{s} = V + at,$$

and again

$$s = s_0 + Vt + \tfrac{1}{2}at^2.$$

As an instance of the indirect problem—*i.e.*, to find the speed, and its rate of increase, when the law of the motion is given:—suppose

$$s = a\cos\omega t.$$

(This equation describes the simplest form of vibratory motion, and will be fully treated later.) We have, by taking the fluxion,

$$\dot{s} = -a\omega\sin\omega t,$$

and again

$$\ddot{s} = -a\omega^2\cos\omega t = -\omega^2 s.$$

§ 30. Velocity, as we have already said, involves the ideas of speed and of direction of motion conjointly.[1] To compound two velocities (as is required in the application of Newton's Second Law), we have the following obvious construction. From any fixed point O (fig. 2), draw a line OA representing, in magnitude and direction, one of the two velocities. From its extremity A draw AB representing in the same way, and on the same scale, the other. Complete the triangle OAB. Then OB represents, in magnitude and direction (still on the same scale), the resultant velocity. We have called the construction obvious because one has only to think of *how* a point can be said to have simultaneous velocities, in order to see its truth. Thus, if OA represents the velocity of a railway train, AB that of a passenger walking in a saloon carriage, O may be looked upon as the position of the point of the carriage at which he began his walk, at the moment when he did begin it; while B represents the position of the point of the carriage which he has reached at the end of his walk, just at the moment when he did reach it. Here OA is the velocity of the carriage relative to the earth, AB that of the passenger relative to the carriage. This proposition may be called the triangle of velocities. Another obvious mode of stating it is to complete the parallelogram of which OB is a diagonal (fig. 3); and then we have the same construction in the form:—If the two velocities to be compounded, represented by OA and OC, be taken as contiguous sides of a parallelogram, the conterminous diagonal OB represents their resultant.

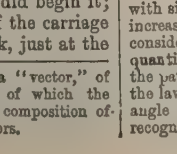

Fig. 2.

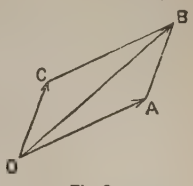

Fig. 3.

§ 31. From the triangle of velocities we may pass at once to the polygon of velocities, which gives us the resultant of any number of simultaneous velocities. Thus, beginning as above at any point O (fig. 4), lay off OA, AB, BC (however many there may be) as successive sides of a polygon *all taken in the same direction round*. The separate velocities may be in one plane or not. When this is done, the final point C is easily seen to be independent of the *order* in which the separate velocities were taken, and is thus a perfectly definite point. OC, completing the polygon, represents the resultant velocity. But it is taken *in the opposite direction round*. If C coincide with O, there is no resultant;—*i.e.*, a point which has, simultaneously, velocities represented by the successive sides of any polygon, all taken the same way round, is at rest. Composition of velocities

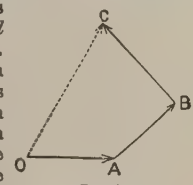

Fig. 4.

In what precedes, we have denoted the position of the moving point in its known path by the single quantity $s$. But if we think of its Cartesian coordinates $x$, $y$, $z$, we see that in general each of these must vary during the motion. And just as we represented the whole speed by $\dot{s}$ so we may speak of $\dot{x}$ as the speed in the direction of the axis of $x$, &c. And now we have a hint of a most important character. For, by the ordinary laws of the differential calculus, we have three equations of the form

$$\frac{\dot{x}}{\dot{s}} = \frac{dx}{ds} \text{ or } \dot{x} = \frac{dx}{ds}\dot{s}.$$

Now $\frac{dx}{ds}$ is the cosine of the inclination of the tangent at $s$ to the axis of $x$. And so with $\dot{y}$ and $\dot{z}$. These give us

$$\dot{x}^2 + \dot{y}^2 + \dot{z}^2 = \dot{s}^2\left(\left(\frac{dx}{ds}\right)^2 + \left(\frac{dy}{ds}\right)^2 + \left(\frac{dz}{ds}\right)^2\right) = \dot{s}^2.$$

Hence we see that a speed in any direction may be resolved into three in any assigned directions at right angles to one another; that the speed in any one of these is determined by multiplying the whole speed by the cosine of the angle between its direction and that of its resolved part; and that the square of the whole speed is the sum of the squares of the speeds in the resolved motions. These results, however, can be obtained more directly, and in a more instructive manner, by the consideration of "velocities," and not of mere "speeds." But, before we take this step, let us take the second fluxions of the coordinates, and see to what they lead us.

From

$$\dot{x} = \frac{dx}{ds}\dot{s}$$

we obtain at once

$$\ddot{x} = \frac{dx}{ds}\ddot{s} + \frac{d^2x}{ds^2}\dot{s}^2;$$

or, introducing in the last term, both as a multiplier and as a divisor, the radius of curvature of the path,

$$\ddot{x} = \frac{dx}{ds}\ddot{s} + \rho\frac{d^2x}{ds^2}\cdot\frac{\dot{s}^2}{\rho},$$

with similar expressions for $\ddot{y}$ and $\ddot{z}$. These show that the rates of increase of speed, parallel to the three axes respectively, may be considered as made up of the resolved parts of the two directed quantities $\ddot{s}$ and $\dot{s}^2/\rho$. The first is in the direction of the tangent to the path, the second in the direction of the radius of curvature; and the law of resolution is, for each, multiplication by the cosine of the angle between the two directions concerned. We shall presently recognize these as the components of the acceleration.

[1] It is, in fact, in the language of quaternions, a "vector," of which the speed is the "tensor" or length, and of which the "versor" assigns the direction. And the laws of composition of velocities are in all respects the same as those of vectors.

Resolution of velocity.

§ 32. To resolve a velocity is of course a perfectly indefinite problem, unless the number of conditions requisite for definiteness be imposed. For, in general, it may be taken as one side of any complete polygon, whether in one plane or not; and the other sides, all taken in the opposite order round, represent its components.

The only cases which we need consider, in which the conditions are such as to ensure one definite solution, are—(1) when a velocity is to be resolved into components parallel and perpendicular to a given line; and (2) an extension of the same case to components parallel respectively to three lines at right angles to one another. In case (1) the given velocity is to be taken as the hypotenuse of a right-angled triangle of which one of the sides is parallel to the given line. In case (2) it is to be taken as the diagonal of a rectangular parallelepiped of which the edges are parallel to the three lines respectively. In either case the magnitude of each component is found by multiplying the amount of the velocity by the cosine of the angle between its direction and that of the component; and the square of the whole velocity is equal to the sum of the squares of the components. We are now prepared to take up the requisite preliminaries for the application of the Second Law. What, in fact, is "change of velocity"? The preceding statements at once enable us to give the answer. For let OA (fig. 5) be the velocity of a point at one instant, OB at a succeeding instant. To convert OA into OB, we must compound with it a velocity represented by AB. AB represents the change. Hence if, during any motion *whatever* of a point, a line OA be constantly drawn from a fixed point O, so as to represent at every instant the magnitude and direction of the velocity of the moving point, the extremity of OA will describe a curve (plane if the original path be plane, but not otherwise, except in certain special cases) which possesses the following important but obvious properties:—(1) the tangent at A is the direction of the change of velocity in the original path; (2) the rate of motion of A is the rate of change of velocity in the original path. Hence in this auxiliary curve, called the HODOGRAPH (*q.v.*), the velocity represents, in magnitude and direction, what is called "acceleration" in the original path. And, because the acceleration can thus be represented as a velocity, the laws of composition and resolution of velocities hold good for accelerations also.

Change of velocity.

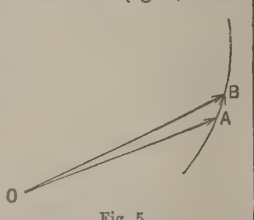

Fig. 5.

Hodograph.

Acceleration.

§ 33. Hence, if we desire to know the whole acceleration in any case of motion of a point, we need only find its components in, and perpendicular to, the tangent to the path. That in the tangent has already been found; it is $\dot{v}$ or $\ddot{s}$ as in § 29. For that perpendicular to the path we may study the simple case of uniform motion in a circle.

Acceleration in uniform circular motion.

§ 34. If a point move with uniform speed V in a circle, the hodograph is evidently a circle of radius V, and is described uniformly in the same time as the orbit (see fig. 6). Hence the speeds in the two circles are as their radii. Let R be the radius of the orbit. Then the magnitude of the acceleration in the orbit (the speed in the hodograph) is found from

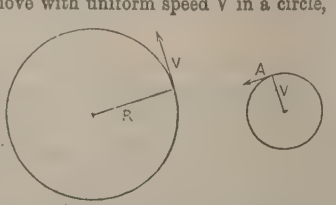

Fig. 6.

$$A : V :: V : R;$$

that is,

$$A = V^2/R.$$

The direction of this acceleration, being that of the tangent to the hodograph, is perpendicular to the corresponding radius of the hodograph, *i.e.*, to the tangent to the orbit. Hence it is *along the radius of the orbit and directed inwards to its centre.*

The so called centrifugal force.

§ 35. In other words, to *compel* a mass to describe an *unnatural* (because curved) path, it must be acted on by a force directed towards the centre of curvature of the path. We anticipate so far as to introduce here mass and force, although, strictly, we are dealing with kinematics. But the student cannot be too early warned of the dangerous error into which so many have fallen, who have supposed that a mass has a tendency to fly *outwards* from a centre about which it is revolving, and therefore exerts a "centrifugal force," which requires to be balanced by a "centripetal force." The centripetal force is required if the path is to be curved; it is required for the purpose of *producing the curvature*, and not because there is any tendency to fly out from the centre.

Components of acceleration.

§ 36. Thus, in any motion of a point, the whole acceleration is the resultant of two parts—the first in the direction of motion and of magnitude equal to the rate of increase of speed, the second directed towards the centre of curvature and of magnitude as the curvature and the square of the speed conjointly. The sole effect of the first component is to alter the *speed*, of the second to alter the *direction*, of the motion. There is no acceleration perpendicular to the osculating plane, because two successive values of the velocity, and therefore also the corresponding *change of velocity*, are in that plane.

Angular velocity.

§ 37. A very convenient expression for acceleration which changes the direction of motion is furnished in terms of what is called the "angular velocity," *i.e.*, the rate at which direction changes. This also is properly a vector, or directed line, perpendicular to the plane in which the change of direction takes place, and of length proportional to the rate at which the angle assigning the direction changes.

§ 38. In the case of uniform motion in a circle of radius R, with speed V, the time of describing the complete circumference ($2\pi R$) is $2\pi R/V$. Hence the angular velocity is $V/R$, usually denoted by $\omega$. Thus the above expression for the acceleration in a direction perpendicular to the path of a point (§ 34) may be written in the form $\rho\omega^2$, where $\rho$ is the radius of curvature of the orbit and $\omega$ the angular velocity of that radius. The direction of this acceleration, as we have seen, is always towards the centre of curvature.

§ 39. The general difficulty of any question concerning acceleration is usually a purely mathematical one, involving only such physical considerations as are required for the formation of the differential equations, and for the determination of the so-called arbitrary constants or arbitrary functions involved in the integrals. We will not now discuss the various forms in which the difficulty may present itself, because in the course of the article many of the more important of these will be fully treated in connexion with motions actually observed among terrestrial or cosmical bodies.

Uniform acceleration parallel to a fixed line.

§ 40. We have sufficiently considered (§§ 27–29) uniform acceleration in the line of motion. Let us now consider uniform acceleration in a fixed direction, whether the motion of the point be in that direction or not. This is the most general case of the motion of an *unresisted* projectile, on the supposition that its path is confined to a region throughout which gravity is sensibly constant alike in direction and in intensity. Two well-known properties of the parabola lead to an immediate solution of our problem.

Let fig. 7 represent a parabola, defined completely by

its focus S and its directrix MN. We suppose it to be placed with its axis vertical, and vertex upwards. Take any point P, join PS, and draw PM perpendicular to the directrix. Then

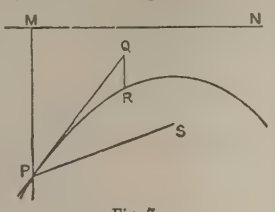

Fig. 7.

(*a*) If PQ bisect the angle SPM, it is the tangent to the parabola at P.

Let Q be any point in the tangent, and let QR, drawn parallel to MP, meet the curve in R. Then we have

(*b*) $PQ^2 = 4SP.QR$.

Path of an unresisted projectile.

§ 41. Now suppose a point, originally moving along PQ with uniform speed V, to have its motion accelerated in a direction parallel to MP, the acceleration being $a$, a constant. Then, after $t$ seconds it would have moved along PQ through a space $Vt$, and parallel to MP through a space $\frac{1}{2}at^2$. Hence, if R be its position at that time,

$$PQ = Vt, \quad QR = \tfrac{1}{2}at^2.$$

From these equations we find at once

$$PQ^2 = \frac{2V^2}{a}QR.$$

This relation is of the same form as that already written for a parabola, and (as it does not involve $t$) it holds for every point of the path. Hence the point moves in a parabola whose axis is vertical, which touches PQ (the direction of projection) in P, and in which $SP = V^2/2a$. But these three data determine the parabola. For we have only to draw PM vertical, make the angle QPS = QPM, and measure off the lengths PM and PS each equal to $V^2/2a$. M is a point in the (horizontal) directrix, and S is the focus. Hence the path is completely determined.

It is well to notice that, as $V^2 = 2aPM$, M is the point which the projectile would just reach if it were projected vertically upwards (§ 29).

Examples of motion of projectile.

§ 42. If the speed of projection be kept constant, while the direction of PQ alters in a vertical plane, S describes a circle about P as centre. This consideration enables us easily to *find the direction of projection that a given object may be struck.* Let O (fig. 8) be the object. Join PO, and let it cut in B the circle MBS (whose centre is P). Draw ON perpendicular to the common directrix, and with radius ON describe a circle about O. This will (in general) cut MBS in two points F and F'. *These are the foci of the two paths by either of which the projectile can reach O.* For by construction FO = ON, so that O lies on the path whose focus is F. Similarly for F'.

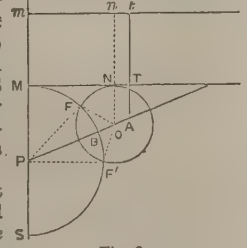

Fig. 8.

To find the most distant point along PO which can be reached, with the given speed of projection from P, we have merely to note that, as O is taken farther and farther from P, F and F' approach B, and finally coincide with it. If O be then at A, we have AT = AB, where AT is perpendicular to the directrix. Hence, if we produce AT to $t$ so that $Tt = BP$, we have $At = AP$. Draw through $t$ a line $tm$ parallel to TM. Then A lies on the parabola whose focus is P and directrix $mt$. This parabola is the envelop of all the possible paths from P. Any point within it can be reached by two different paths. These become coincident when the point lies on the curve; and no point outside it can be reached.

§ 43. Many of the most important cases of motion of a point involve acceleration whose direction is always towards a definite "centre" as it is called. In such cases the motion is obviously confined to the plane which, at any instant, contains the centre and the line of motion of the point. Acceleration to fixed centre.

Also the "moment" of the point's velocity about the centre remains constant. Here a slight digression is necessary.

Moment.

DEF.—*Given a directed quantity (a velocity, force, &c.) in a line AB* (fig. 9). *If a perpendicular OP be drawn to AB from any point O, the "moment" of the directed quantity about O is the product of its amount by the length of the perpendicular.*

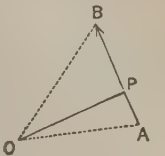

Fig. 9.

If the directed quantity be reversed, the *sign* of the moment is changed. The moment is, in fact, properly a directed quantity (or vector) perpendicular to the plane OAB. And its numerical magnitude is double the area of the triangle OAB.

[§ 44. The convention usually made as to the sign of rotation about an axis is to regard it as positive when it is in the same sense as that in which the earth turns about its axis, as seen by a spectator above the north pole. This is in the opposite direction to that of the hands of a watch. Hence the plane angle AOP (fig. 10), representing the change of direction of a line originally coincident with OA, is positive, and is looked on as due to rotation about an axis drawn from O *upwards* from the plane of the figure. Thus the rotation of the sun and the orbital motions of the planets take place in the positive direction about axes drawn on the whole northwards from the plane of the ecliptic; or we may put it thus:—seizing an axis by the positive end, we must *unscrew*—by the negative end, we must screw—to give positive rotation. And when, later, we consider rotations about three rectangular axes, $Ox$, $Oy$, $Oz$, we shall suppose them so drawn that rotation through a positive right angle

Convention as to sign of angle, angular velocity, &c.

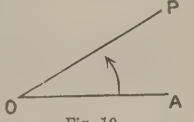

Fig. 10.

about $Ox$ changes $Oy$ into $Oz$,
„ $Oy$ „ $Oz$ „ $Ox$,
„ $Oz$ „ $Ox$ „ $Oy$,

the three letters being throughout arranged in cyclical order, $xyz$, $yzx$, &c.]

§ 45. Here we must introduce a simple geometrical proposition:— Geometrical proposition.

*If any point be taken in the plane of a parallelogram, and triangles be formed with the point as vertex and with contiguous sides and the conterminous diagonal as their respective bases, the sum of the areas of the first two triangles is equal to the area of the third.*

Thus, in areas (fig. 11),

$$OAB + OAC = OAD.$$

If O lie within the angle BAC, as in fig. 12, the proposition becomes

$$OAC - OAB = OAD.$$

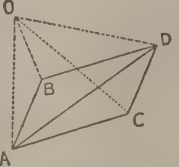

Fig. 11.

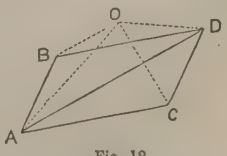

Fig. 12.

§ 46. Remembering that these areas represent half the moments of the bases of the respective triangles about the

point O (that of OAB being *negative* in the second case above), we see that

*The moment of a diagonal of a parallelogram about any point in the plane of the figure is the* (*algebraic*) *sum of the moments of two conterminous sides.*

Now, suppose the sides of the parallelogram to represent a velocity and its change. If the direction of the change pass through O, its moment is *nil*. Hence, *for acceleration directed towards a fixed point the moment of the velocity about that point is constant.*

Equable description of areas.

This is commonly expressed by saying that *the radius-vector describes equal areas in equal times about the point to which the acceleration is directed.* For the moment of the velocity is double the area so traced in unit of time.

Another way of expressing the same thing is to say that the angular velocity of the radius-vector is inversely as the square of its length. For the product of the square of the radius-vector and its angular velocity is double the area described by it in unit of time.

The converse of this proposition is also evidently true; *i.e., when a point moves so that the moment of the velocity about a point in the plane of its motion is constant, its acceleration relative to that point* (*if any*) *is directed towards or from that point.*

Analytical treatment of central acceleration.

§ 47. Analytically: if P be the acceleration, directed towards a fixed point which we choose as origin, we have

$$\ddot{x} = -P\cos\theta = -Px/r,$$
$$\ddot{y} = -P\sin\theta = -Py/r,$$

($r$ and $\theta$ being the polar coordinates of the moving point; we have already seen that the path is necessarily plane). Eliminating P, we have

$$0 = x\ddot{y} - y\ddot{x} = \frac{d}{dt}(r^2\dot{\theta}).$$

Thus
$$x\dot{y} - y\dot{x} = r^2\dot{\theta} = \text{const.} = h.$$

This may be transformed, at once, by the methods of the differential calculus, into

$$p\dot{s} = pv = h,$$

where $p$ is the length of the perpendicular from the origin to the tangent to the path. Conversely, if equal areas be described by the radius-vector in equal times, we have

$$r^2\dot{\theta} = x\dot{y} - y\dot{x} = \hbar.$$

Whence
$$x\ddot{y} - y\ddot{x} = 0,$$

or
$$\ddot{x} = Qx, \quad \ddot{y} = Qy.$$

Hence the whole acceleration is $Qr$, and is directed towards or from the origin.

Polar coordinates.

While we are dealing with these formulæ we may investigate the general expressions for velocity and acceleration in terms of polar coordinates for a point moving in a plane.

We have
$$x = r\cos\theta, \quad y = r\sin\theta.$$
From these
$$\dot{x} = \dot{r}\cos\theta - r\dot{\theta}\sin\theta,$$
$$\dot{y} = \dot{r}\sin\theta + r\dot{\theta}\cos\theta.$$

Hence the speed along the radius-vector is

$$\dot{x}\cos\theta + \dot{y}\sin\theta = \dot{r};$$

and that perpendicular to the radius-vector (in the direction in which $\theta$ increases) is

$$\dot{y}\cos\theta - \dot{x}\sin\theta = r\dot{\theta}.$$

These expressions might have been written down at once, if we note that $\delta r$ and $r\delta\theta$ are the resolved parts of $\delta s$ along, and perpendicular to, $r$. But we must be careful how we carry this species of reasoning one step further. Taking the second fluxions of $x$ and $y$, we have

$$\ddot{x} = (\ddot{r} - r\dot{\theta}^2)\cos\theta - (2\dot{r}\dot{\theta} + r\ddot{\theta})\sin\theta,$$
$$\ddot{y} = (\ddot{r} - r\dot{\theta}^2)\sin\theta + (2\dot{r}\dot{\theta} + r\ddot{\theta})\cos\theta.$$

Hence the acceleration along the radius-vector is

$$\ddot{x}\cos\theta + \ddot{y}\sin\theta = \ddot{r} - r\dot{\theta}^2,$$

and that perpendicular to it (positive when in the direction in which $\theta$ increases) is

$$\ddot{y}\cos\theta - \ddot{x}\sin\theta = 2\dot{r}\dot{\theta} + r\ddot{\theta} = \frac{1}{r}\frac{d}{dt}(r^2\dot{\theta}).$$

Thus, although $\dot{r}$ represents truly the speed along $r$, $\ddot{r}$ does not represent the acceleration in that direction. It represents, in fact, only the *acceleration of speed* along $r$. But we have seen that there is acceleration along $r$, if its direction changes, even when its length is constant, *i.e.*, when the path is circular; and in that case $r\dot{\theta}^2$ is the quantity which we designated as $\rho\omega^2$ in § 38.

As a verification of these formulæ, let us consider uniform motion in a straight line.

Here
$$r\cos\theta = a,$$
the equation of the straight line, and
$$a\tan\theta = Vt,$$
the condition of uniform motion. We have

$$\dot{r} = a\sec\theta\tan\theta.\dot{\theta},$$
$$V = a\sec^2\theta.\dot{\theta} = r^2\dot{\theta}/a;$$
$$\dot{r} = V\sin\theta,$$
$$\ddot{r} = V\cos\theta.\dot{\theta} = \frac{aV}{r}\dot{\theta} = \frac{a^2V^2}{r^3}$$

Here, although there is no acceleration, $\ddot{r}$ has a definite value. But

$$\ddot{r} - r\dot{\theta}^2 = a^2V^2/r^3 - a^2V^2/r^3 = 0,$$

From the expressions for the acceleration along and perpendicular to the radius-vector we at once obtain the result above (§ 46). For, if there be no acceleration perpendicular to the radius-vector, we have

$$\frac{1}{r}\frac{d}{dt}(r^2\dot{\theta}) = 0,$$

from which

$$r^2\dot{\theta} = \text{const.} = h.$$

We have, in addition to this, the expression for the acceleration towards the origin,

$$\ddot{r} - r\dot{\theta}^2 = -P.$$

Eliminating $\dot{\theta}$, we have

$$\ddot{r} - h^2/r^3 = -P.$$

This gives $r$ in terms of $t$, and thus reduces (if we please) any case of a central orbit to a corresponding case of rectilinear motion. The difference between the accelerations in the revolving radius-vector and in the fixed line is a term depending on the inverse cube of the radius-vector. But the usual mode of proceeding is as follows.

Reduction to case of rectilinear motion.

Multiply by $\dot{r}dt$ and integrate, then

$$\dot{r}^2 + \frac{h^2}{r^2} = C - 2\int P dr;$$

or
$$\left(\frac{dr}{d\theta}\right)^2\frac{h^2}{r^4} + \frac{h^2}{r^2} = C - 2\int P dr.$$

The left-hand member obviously represents the square of the velocity, as it is the sum of the squares of $\dot{r}$ and $r\dot{\theta}$. For we have

$$\dot{r} = \frac{dr}{d\theta}\dot{\theta} = \frac{dr}{d\theta}\frac{h}{r^2}.$$

This gives a relation between $r$ and $\theta$, which is therefore the polar equation of the path described. It is usual to employ, instead of $r$, its reciprocal $1/r = u$. With this the equation becomes

$$h^2\left(\left(\frac{du}{d\theta}\right)^2 + u^2\right) = C + 2\int\frac{P du}{u^2}.$$

Differentiating with regard to $\theta$, and dividing by $2h^2\frac{du}{d\theta}$, we obtain finally

$$\frac{d^2u}{d\theta^2} + u = \frac{P}{h^2u^2},$$

Polar equation of path.

an equation of very great importance.

When there is acceleration T perpendicular to the radius-vector, as well as $-P$ along it, this equation takes the form

$$\frac{d^2u}{d\theta^2} + u = \frac{\frac{P}{u^2} - \frac{T}{u^3}\frac{du}{d\theta}}{h^2 + 2\int\frac{T}{u^3}d\theta}.$$

Special cases.

§ 48. **There are two specially important cases of central acceleration.** The first is that of the gravitation law, the other that of Hooke's law. We will take these in order, but by very different methods.

Planetary motion.

§ 49. *Planetary Motion.*—With the gravitation law the acceleration varies inversely as the square of the distance from the point to which it is directed. But, as we have just seen, the angular velocity of the radius-vector, *i.e.*, of the direction of acceleration, varies according to the same law. Hence in the hodograph, the linear velocity (whose *magnitude* is that of the acceleration in the path) is pro-

portional to the angular velocity of the tangent (whose direction is parallel to the acceleration).

Circular hodograph.

Thus, in the hodograph, the angle between successive tangents is proportional to the arc between their points of contact; and therefore the curvature is constant;—*i.e.*, *the hodograph is a circle.*

Form of planetary orbit.

Let A (fig. 13) be the centre of this circle, O the pole of the hodograph, P any position of the tracing point. Then OP is, in magnitude and direction, the velocity in the orbit. But it may be looked on as consisting of two parts, OA and AP. Of these both are constant in magnitude; but OA is constant in direction, while AP is perpendicular to the direction of acceleration in the orbit. Hence the velocity in the orbit is the resultant of two constant parts,—one always in a fixed direction, the other always perpendicular to the radius-vector.

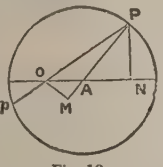

Fig. 13.

This gives the form of the orbit as follows:—

$$\dot{x} = a(e - y/r),\ \dot{y} = ax/r;$$

so that $$r\dot{r} = x\dot{x} + y\dot{y} = er\dot{y},$$

or $$r = e(y + b);$$

where the meanings of the quantities are obvious.

But if PO cut the circle again in $p$, $Op$ is proportional to the perpendicular on the tangent to the orbit from the centre of acceleration (because PO.$Op$ is constant) and is at right angles to it (because it is in the direction of the velocity). Hence the path is such that the locus of the foot of the perpendicular from the centre of acceleration on the tangent is a circle. This property belongs exclusively to conic sections, one focus being the point from which the perpendiculars are drawn.

A third and even simpler mode of treating this most important problem is as follows. Draw OM perpendicular to PA (produced if necessary) and PN perpendicular to OA. Then OM is the resolved part of OP parallel to the tangent at P, *i.e.*, it is the speed with which the length of the radius-vector changes. Also PN is the resolved part of OP perpendicular to the fixed line OA, *i.e.*, it is the speed with which the moving point travels in a fixed direction. But by similar triangles OAM, PAN, we have

$$\text{OM} : \text{PN} :: \text{OA} : \text{AP} = \text{a constant ratio.}$$

Hence the increment of the radius-vector bears a constant ratio to the simultaneous increment of the distance of the moving point from a fixed line in the plane of motion. This is only a slightly altered form of statement of the focus and directrix property of conic sections.

When O is within the circle, the constant ratio is less than unity, and the conic is an ellipse; when without, the ratio is greater than unity, and we have an hyperbola. When O is on the circumference of the hodograph, the path is a parabola; for the ratio is unity.

In a subsequent section we will return to this question, and treat it from the point of view of Kepler's Laws of Planetary Motion.

Analytical proof.

Simple as are the geometrical methods above, the direct analytical one is still simpler. For we have

$$\mathrm{P} = -\frac{\mu}{r^2},$$

so that $$\ddot{x} = -\frac{\mu}{r^2}\cos\theta,\quad \ddot{y} = -\frac{\mu}{r^2}\sin\theta.$$

Hence, as before (§ 47),

$$x\dot{y} - y\dot{x} = r^2\dot{\theta} = h;$$

and therefore, by eliminating $r^2$, we have

$$\ddot{x} = -\frac{\mu}{h}\cos\theta\,.\,\dot{\theta},\quad \ddot{y} = -\frac{\mu}{h}\sin\theta\,.\,\dot{\theta},$$

so that $$\dot{x} - \alpha = -\frac{\mu}{h}\sin\theta,\quad \dot{y} - \beta = +\frac{\mu}{h}\cos\theta.$$

These give at once, by squaring and adding,

$$(\dot{x} - \alpha)^2 + (\dot{y} - \beta)^2 = \mu^2/h^2,$$

the equation of the circular hodograph. Also, by multiplying the first by $y$, and subtracting it from the second multiplied by $x$, we have

$$h - \beta x + \alpha y = r\mu/h,$$

the equation of the orbit. This is evidently a conic section of which the origin is a focus. The directrix corresponding is the line

$$\alpha y - \beta x + h = 0,$$

and the excentricity is

$$h\sqrt{\alpha^2 + \beta^2}/\mu.$$

From these the major axis can be calculated.

Central acceleration proportional to radius-vector.

§ 50. *Elliptic Motion about the Centre.*—When a point moves uniformly in a circle, the motion presents very different appearances according to the spectator's point of view. If we suppose him to be situated at a distance very great compared with the radius of the circle, he sees what is practically an orthographic projection of the orbit on a plane perpendicular to the line of sight. In general, an orthographic projection of a circle is an ellipse—whose centre is the projection of that of the circle. As equal areas are projected orthographically into equal areas, the appearance is therefore elliptic motion, in which the radius-vector from the centre describes equal areas in equal times. Hence (§ 46) the acceleration is directed towards the centre. But accelerations are projected like velocities, and like lines. Hence, as the acceleration in uniform circular motion is constant, and directed towards the centre, so in elliptic motion, with equable description of areas about the centre, the acceleration is towards the centre, and is *proportional to the length of the radius-vector.*[1] But this projected orbit may again be projected orthographically, as often as we please, on different planes. It will always remain elliptical, and with the radius-vector from the centre describing equal areas in equal times. And the acceleration will always be in the same proportion as before to the radius-vector. However different in size and shape these elliptic orbits may be, they have one common property, *the time of describing them is the same.*

Thus we see that when the orbit is an ellipse described about its centre of figure the acceleration is central, and proportional to the radius-vector. The time of describing such an ellipse depends only upon the *ratio* of the acceleration to the length of the radius-vector; or, if we choose, upon the magnitude of the acceleration at unit distance. And the converse of this proposition is also evidently true. When we look edgewise at the uniformly-described circular path with which we commenced, it is seen projected into a straight line, in which the moving point appears to *oscillate.* This is the case, for instance, very approximately, with the satellites of Jupiter as seen from the earth. Sun-spots, the red-spot on Jupiter, &c., all appear to move approximately in this way. But the extreme importance of this species of motion is that it is the simplest type of oscillation of a particle of matter displaced from a position of stable equilibrium. The vibrations of the ether when homogeneous plane-polarized light is passing through it, of the air when a pure musical note is sounded, the oscillations of a pendulum (through small arcs), the simplest vibrations of a pianoforte wire or a tuning-fork, the indications of a tide-gauge when the sea is calm,—all are instances of it. Hence the special necessity for studying it in detail.

Simple harmonic motion.

§ 51. DEF.—*Simple harmonic motion is the resolved part, parallel to a diameter, of uniform circular motion.*

[1] The elastic force called into play by displacement is, by Hooke's law, proportional to the displacement, and tends to restore the displaced particle to its equilibrium position. We mention this, in passing, to show the importance of the present investigation.

Let a point P (fig. 14) move uniformly in the circle APA′. Then, drawing any diameter AOA′, and PM perpendicular to it, the motion of M is simple harmonic.

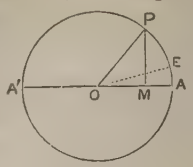

Fig. 14.

The speed and acceleration of M are obviously the resolved parts, along AA′, of the speed and acceleration of P. Hence if V be the speed of P we have

$$\text{speed of M} = \frac{\text{PM}}{\text{PO}}\text{V},$$

$$\text{acceleration of M} = \frac{\text{MO}}{\text{PO}} \times \text{acceleration of P}$$

$$= \frac{\text{MO}}{\text{PO}} \cdot \frac{\text{V}^2}{\text{PO}} = \frac{\text{V}^2}{\text{PO}^2}\,\text{MO}.$$

From these expressions we see that, if we call $\omega$ the angular velocity of OP, so that $\omega = \text{V/PO}$, we have

$$\text{speed of M} = \text{PM}.\omega,$$

$$\text{acceleration of M} = \text{MO}.\omega^2.$$

Thus the speed of M increases from A to O,—being zero at A, and V at O; then it falls off to zero at A′, and goes through the same numerical values in the opposite order, when the direction of motion is reversed at A′.

The acceleration of M is always directed *towards* O. It has its greatest value at A and again at A′, and is always *proportional to the distance from O*. If T be the *period* of the simple harmonic motion, *i.e.*, the period of rotation of P in the circle, we have

$$\text{T} = \frac{2\pi}{\omega} = \frac{2\pi}{\text{V}}a,$$

Amplitude.

where $a$ is the radius of the circle, or, as it is also called, the "amplitude" of the simple harmonic motion. We may now write as the characteristic of this species of motion

$$\text{acceleration} = \frac{4\pi^2}{\text{T}^2} \times \text{displacement};$$

or

$$\text{T} = 2\pi\sqrt{\frac{\text{displacement}}{\text{acceleration}}}.$$

Phase and epoch.

§ 52. In our further remarks about simple harmonic motion the following terms will be found convenient. P is the position at time $t$ of the point moving in the circle. Let E be its position at the zero of reckoning, when $t = 0$. Then the angle AOP may be called the "phase" of the simple harmonic motion, and AOE the "epoch." In time units the values of the phase and epoch are found from their circular measure by dividing by $\omega$.

If the position of the point moving with simple harmonic motion be denoted by $x$, we obviously have

$$\begin{aligned} x &= \text{OM} = \text{OP}\cos\text{POA}, \\ &= \text{OP}\cos(\text{POE} + \text{EOA}), \\ &= a\cos(\omega t + \epsilon). \end{aligned}$$

This expression is to be found, perhaps more frequently than any other, in all branches of mathematical physics. It is in terms, or series of terms, of this form that *every* periodic phenomenon can be described mathematically, as will be seen later. From the expressions for the longitude and radius-vector of a planet or a satellite to those of the most complex undulations whether in water, in air, or in the luminiferous medium, all are alike dependent upon it.

The results obtained geometrically above are easily reproduced from this form:—

thus $\dot{x} = -a\omega\sin(\omega t + \epsilon)$;

and $\ddot{x} = -a\omega^2\cos(\omega t + \epsilon) = -x\omega^2$.

Graphic representation.

§ 53. The simplest graphical method of exhibiting the nature of any kind of rectilineal motion is to compound it with a uniform velocity in a direction perpendicular to the line in which it is executed. This is, in fact, what is done in the majority of *self-registering* instruments, where a slip of paper is drawn by clock-work uniformly past the moving point, in a direction perpendicular to its line of motion, and a record is made by mechanical means, by a pencil, by an electric spark, or (best of all) by photographic processes. When this process is applied to a simple harmonic motion the record is of the general form of the curve in fig. 15. This curve has long been known as

Fig. 15.

the "curve of sines," or the "harmonic" curve. All its forms can be deduced from any one of them by mere extension or foreshortening in the vertical or horizontal directions in the figure. It represents the simplest forms into which a vibrating string can be thrown, as well as the instantaneous form of a section of the surface of water along which a simple series of oscillatory waves or ripples is passing. In this case the *form* of the section remains the same as time goes on, but the whole figure moves steadily onwards in the direction in which the waves are travelling.

This is expressed analytically by the form

Analytical expression for a wave.

$$y = a\cos(nt - mx),$$

where $x$ and $y$ are horizontal and vertical coordinates of a point at the surface of the water, $y$ being measured from the level of the undisturbed surface. When $x$ is constant we study, for all time, the simple harmonic rise and fall at a particular *place*. When $t$ is constant we have the above-figured instantaneous glance of a section of the whole water-surface.

The rate at which the wave travels is obviously $n/m$; for, if we increase $t$ by any quantity $\tau$, and $x$ by the corresponding quantity $n\tau/m$, the value of $y$ is unaltered.

Composition of simple harmonic motions in one line.

§ 54. We have next to consider the result of superposing or compounding two simple harmonic motions which take place in the same line. The geometrical method amply suffices for this purpose provided the *periods* of the two are equal, however different may be their amplitudes and their phases. For, if we suppose PQ (fig. 16) to turn about P in the same plane and with the same angular velocity as OP about O, the angle OPQ will remain unaltered, and therefore the triangle OPQ will remain of constant size and form while turning about O. Thus Q describes a circle about O in the given period. The resolved parts of OP, PQ, along any diameter OA, together make up the resolved part of OQ along the same line. Hence *two simple harmonic motions, of the same period and in the same line, are equivalent to a single simple harmonic motion of the common period.* The amplitude of the resultant simple harmonic motion is OQ, and depends only upon OP, PQ, and the angle OPQ,—the amplitudes of the two component simple harmonic motions and *the supplement of the difference of their phases.*

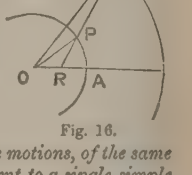

Fig. 16.

Amplitude, &c., of resultant.

§ 55. When the difference of phase is *nil*, or any whole number of circumferences, the resultant amplitude is the sum of the amplitudes of the components, which is its greatest value. When the difference of phase is an odd number of semi-circumferences, the amplitude of the resultant is the difference of those of the components.

If we produce QP to meet OA in R, we see that QOA, the phase of the resultant simple harmonic motion, is intermediate in value to the phases of the components, which are POA and QRA respectively. Its excess over the one, and its defect from the other, are the angles at O and Q in the triangle OPQ; and their sines are to one another as the separate amplitudes QP, PO. Hence, when these amplitudes differ, the phase of the resultant coincides more nearly with that of the component whose amplitude is the greater.

Analytically the resultant motion is expressed by

$$x = a\cos(\omega t+\epsilon)+a'\cos(\omega t+\epsilon'),$$
$$= (a\cos\epsilon+a'\cos\epsilon')\cos\omega t-(a\sin\epsilon+a'\sin\epsilon')\sin\omega t,$$
$$= P\cos(\omega t+Q),$$

provided that

$$P\cos Q = a\cos\epsilon+a'\cos\epsilon',$$
and $$P\sin Q = a\sin\epsilon+a'\sin\epsilon'.$$

These expressions give for the amplitude of the resultant

$$P = \sqrt{(a\cos\epsilon+a'\cos\epsilon')^2+(a\sin\epsilon+a'\sin\epsilon')^2},$$
$$= \sqrt{(a^2+2aa'\cos(\epsilon-\epsilon')+a'^2},$$

This may be put in either of the forms

$$\sqrt{(a+a')^2-4aa'\sin^2\tfrac{1}{2}(\epsilon-\epsilon')} \text{ or } \sqrt{(a-a')^2+4aa'\cos^2\tfrac{1}{2}(\epsilon-\epsilon')},$$

from which the above conclusions follow at once.

Also, for the epoch of the resultant, we have

$$\tan Q = \frac{a\sin\epsilon+a'\sin\epsilon'}{a\cos\epsilon+a'\cos\epsilon'}.$$

When $\epsilon$ and $\epsilon'$ are both positive and less than $\frac{1}{2}\pi$, this is obviously intermediate in value to tan $\epsilon$ and tan $\epsilon'$.

When the periods of the components are not exactly equal, the simple artifice which follows enables us still to apply the same method of composition. We have now

$$x = a\cos(\omega t+\epsilon)+a'\cos(\omega' t+\epsilon'),$$
$$= a\cos(\omega t+\epsilon)+a'\cos(\omega t+\epsilon'+(\omega'-\omega)t).$$

Hence the above values of P and Q will still satisfy the conditions if we write $\epsilon'+(\omega'-\omega)t$ instead of $\epsilon'$. Thus we may treat the two components as being of the same period, but make the epoch of one of them steadily increase with an angular velocity equal to the difference of the angular velocities in the generating circles of the components.

The triangle OPQ will no longer preserve its form; it will pass *continuously* through all the various forms which we have seen would be given to it by various differences of phase in the component simple harmonic motions. The time in which it returns to a former value is evidently $2\pi/(\omega'-\omega)$, which is greater the more nearly equal are the periods of the components.

§ 56. One of the best examples of the principles we have just discussed is furnished by the tides. If there were but one tide-producing body, we should have (approximately) a simple harmonic rise and fall of the sea-level at any given place twice over in the course of about twenty-four hours, and the phase would depend simply upon the distance of the tide-producing body from the meridian (whether above or below the pole). The joint effect of the sun and moon is practically the resultant of the effects which they would separately produce. Hence, when these bodies are in conjunction or in opposition (*i.e.*, at new or at full moon), the whole rise of the tide is the sum of the solar and lunar tides; and we have what are called "spring tides." When the moon is in quadrature, the amplitude of the tidal rise or fall is the excess of the lunar over the solar tide, for it is low water as regards the sun when it is high water as regards the moon. In intermediate positions the effect lies between these extremes, but the joint high-tide lies nearer to the crest of the lunar than to that of the solar tide. In the first and third quarters of the moon, high tide is *earlier* than the high tide due to the moon alone; in the second and fourth *later*. This is what is called "priming" and "lagging" of the tides, and is seen at once to follow from the construction given above. Had the lunar and solar tides been of equal amplitude, spring tides would have been of double the altitude of either, and there would have been no tide at all at the time of neap. Spring and neap tides. Priming and lagging.

The mode in which we have treated this special case is an illustration of the general method (above described) of combining simple harmonic motions in which the periods are slightly different.

§ 57. What we have said of the tide-waves holds of course of all waves in which the separate disturbances are so small that the joint effect is found by superposing the separate effects. Thus when, at sea, two series of waves of equal length meet at any place, the resultant is still a set of waves of the same length, but the altitudes and phases of the components determine those of the resultant. When crest meets crest, we have waves of the sum of the original amplitudes; when crest meets trough, the difference. In the latter case we have still water when the amplitudes of the components are equal. What is called a "jabble,"—where, for a short time, a portion of a stormy sea is almost calm, and after a little it is violently agitated,—is the result of a number of "cross seas." Composition of two wave motions generally.

§ 58. If we now consider the instantaneous form of a section of the surface, instead of the successive displacements of one portion of it, we can easily account for a striking phenomenon which is very frequently observed on a shelving beach. We often notice that every ninth or tenth wave or so is higher than those immediately before or after it. This is the result of superposition of two or more sets of waves in which the distance from crest to crest is different in the different sets. In the joint system we have, represented as in § 53, phenomena akin to the spring and neap tides, and the priming and lagging of the tides. Common phenomena.

Fig. 17 shows part of the result when the amplitudes are equal, and the wave-lengths as 15 to 17. It gives also a rough approximation to the whole result when the lengths are as 7 to 8 or as 8 to 9.

Fig. 17.

§ 59. To compound any number of simple harmonic motions, of equal periods, in one line, we may obviously take them two by two, and apply the preceding process over and over again till we have as final resultant another simple harmonic motion of the common period.

Or thus:—

$$x = \Sigma a\cos(\omega t+\epsilon) = \cos\omega t\,\Sigma(a\cos\epsilon)-\sin\omega t\,\Sigma(a\sin\epsilon) = P\cos(\omega t+Q),$$

where $$P\cos Q = \Sigma(a\cos\epsilon), \quad P\sin Q = \Sigma(a\sin\epsilon).$$

When the separate periods are not equal, and not even *nearly* equal, it is only in special cases that any simplification can be effected by analytical processes. But this is not much to be regretted, because for most purposes a graphic method is sufficiently accurate, and it can always be easily carried out.

§ 60. We must now consider the composition of simple harmonic motions in directions at right angles to each other;—but for the present we confine ourselves to the case in which their periods are equal. In this case we know that the acceleration is in the *same* ratio to the displacement in each of the two rectangular directions. Hence by the general theorem of § 50 the motion is elliptic, with uniform description of areas about the centre.

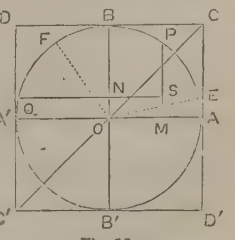

Fig. 18.

To analyse this, suppose, at starting, that their amplitudes also are equal. Let OA, OB (fig. 18) represent the two rectangular directions. With centre O, and radius equal to the common amplitude, describe a circle. Let AOE, BOF represent the epochs of the two components (the corresponding circular motion being supposed positive for each), then obviously EOF exceeds by a right angle the difference between the

Simple harmonic motions at right angles.

phases of the motions in OB and OA. Then if P, Q represent at time $t$ the corresponding positions in the common circle, we have arc FQ = arc EP; and if perpendiculars be drawn, PM to OA, and QN to OB, their intersection S is the position at time $t$ in the resultant motion. The locus of S is, by what has been proved above, an ellipse which touches the sides of the square CDC'D'.

When EOF is a right angle, *i.e.*, when the phases are alike, this ellipse becomes the diagonal CC' of the square touching the circle at the extremities of AA' and BB'. When EOF is three right angles, the ellipse becomes the diagonal DD'. When it is two right angles, or four, *i.e.*, when OB is one quarter, or three quarters, of a period in advance of OA, the ellipse becomes the circle ABA'B'. To find in any case whether it is described positively or negatively (§ 44), we have only to notice how OS turns. Now while P is near A, MS remains closely coincident with AC. If, then, Q be anywhere in the semicircle BA'B', N moves in the direction BB' and the angle AOS *diminishes*. Hence the ellipse is described negatively (or in the direction of the hands of a watch) if the epoch of the motion in OB exceeds that of the motion in OA by anything up to two right angles. And similar reasoning shows that, if the excess be from two to four right angles, the ellipse is described positively.

If the amplitudes be not equal, we have only to extend or foreshorten the figure parallel to OA or to OB. The square CDC'D' becomes a rectangle, in which the orbits (all of which, with the exception of the diagonals, are now ellipses) are inscribed. Everything else is as before.

Periods nearly equal.

§ 61. When the periods in the two component motions are nearly, but not quite, equal, the phase of one gains gradually on the other, and the path passes continuously through the forms of all the possible ellipses, but remains possessed of the one property common to them all. It becomes a species of spiral, but in every convolution it touches, in succession, each side of the square or rectangle above discussed.

Simple harmonic motions of one period, in any directions.

§ 62. Similar reasoning shows that the superposition of any number of simple harmonic motions in any directions and with any amplitudes and differences of phase, provided the period is the same for all, gives rise to motion in an ellipse about the centre. But this follows more easily from analysis.

Take, first, two simple harmonic motions of the same period parallel to the axes of $x$ and $y$. We have

$$x = a\cos(\omega t + \epsilon),$$
$$y = a'\cos(\omega t + \epsilon').$$

Eliminating $t$ between these equations, we have at once

$$\frac{x^2}{a^2} - 2\frac{xy}{aa'}\cos(\epsilon' - \epsilon) + \frac{y^2}{a'^2} = \sin^2(\epsilon' - \epsilon),$$

the equation of an ellipse.

It becomes a circle when and only when

$$a = a', \qquad \cos(\epsilon' - \epsilon) = 0,$$

*i.e.*, when the amplitudes are equal, and the phases differ by an odd number of right angles.

It becomes the straight line

$$x/a - y/a' = 0,$$

when $\epsilon' - \epsilon$ is zero; and

$$x/a + y/a' = 0,$$

when $\epsilon' - \epsilon$ is two right angles.

If SOA be called $\theta$, we have

$$\tan\theta = \frac{y}{x} = \frac{a'\cos(\omega t + \epsilon')}{a\cos(\omega t + \epsilon)}$$
$$= \frac{a'}{a}\left(\cos(\epsilon' - \epsilon) - \sin(\epsilon' - \epsilon)\tan(\omega t + \epsilon)\right).$$

Hence, taking the fluxion of each side,

$$\sec^2\theta \cdot \dot\theta = -\frac{a'}{a}\omega\sin(\epsilon' - \epsilon)\sec^2(\omega t + \epsilon).$$

Thus, as before, $\theta$ is essentially negative, *i.e.*, the rotation in the ellipse is right-handed if $\epsilon' - \epsilon$ lie between 0 and $\pi$, left-handed if it lie between $\pi$ and $2\pi$.

For a simple harmonic motion, denoted by

$$\xi = a\cos(\omega t + \epsilon),$$

in a line whose direction cosines are $l$, $m$, $n$, we have the components $l\xi$, $m\xi$, $n\xi$ parallel to the three axes respectively. Hence for the resultant of any number of such, *all having the same period*, we have

$$x = \Sigma . al\cos(\omega t + \epsilon) = \cos\omega t\,\Sigma(al\cos\epsilon) - \sin\omega t\,\Sigma(al\sin\epsilon).$$

Thus we have three equations of the form

$$x = A\cos\omega t - A'\sin\omega t,$$
$$y = B\cos\omega t - B'\sin\omega t,$$
$$z = C\cos\omega t - C'\sin\omega t.$$

If we take three quantities $\lambda$, $\mu$, $\nu$, such that

$$\lambda A + \mu B + \nu C = 0,$$
$$\lambda A' + \mu B' + \nu C' = 0,$$

we have also

$$\lambda x + \mu y + \nu z = 0.$$

The first two equations determine without ambiguity the ratios of $\mu$ and $\nu$ to $\lambda$. Hence the third is the equation of a definite *plane* in which the path lies. We may now choose this plane as that of $x$, $y$. The value of $z$ above becomes identically zero; and the elimination of $t$ between the equations for $x$ and $y$ gives the ellipse as before.

Periods not equal

§ 63. When the periods of the simple harmonic motions are not equal we have

$$x = a\cos(\omega t + \epsilon), \qquad y = a'\cos(\omega' t + \epsilon').$$

It is easy to trace the corresponding curve by points; but, except when there is a simple numerical ratio between $\omega$ and $\omega'$, the equation cannot be presented as an algebraic one between $x$ and $y$. If $2\omega' = \omega$, we may shift the epoch so that the equations may be written

$$x = a\cos(2\omega' t + \alpha), \qquad y = a'\cos\omega' t.$$

Eliminating $t$ from the first, by the help of the second, we have

$$\frac{x}{a} = \left(\frac{2y^2}{a'^2} - 1\right)\cos\alpha - \frac{2y}{a'}\sqrt{1 - \frac{y^2}{a'^2}}\sin\alpha.$$

This denotes, in general, a curve of the fourth order, of a figure-of-8 form, as in fig. 19. When $\alpha = n\pi$ the curve is a portion of a

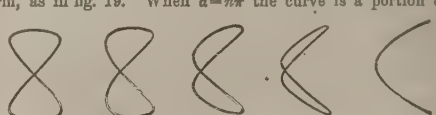

Fig. 19.

parabola, its vertex being to the right or left as $n$ is odd or even. This parabola corresponds, in the present case, to the straight lines in the case of § 62. When the periods differ slightly from the ratio 2 : 1, the path passes in succession through the forms traced, forward and backward alternately; and, each time that it opens out from the parabolic form, the tracing-point describes it in the opposite direction to that in which it described it before the path collapsed into the parabola.

Composition of uniform circular motion

§ 64. The principles already illustrated are sufficient for the examination of every case of this kind. But one or two particular cases merit special notice. The case of two uniform circular motions of equal periods, in one plane, we have already noticed (§ 54). Q describes its circle about P, P its circle about O, and the result is uniform circular motion of Q about O. The radius of this circle may be equal to the sum or difference of the radii of the separate circles, or may have any intermediate value, according to the difference of phase. If the periods be not exactly equal, the motion takes place virtually in a circle whose radius continuously oscillates between the above limits. The path is a species of spiral, which lies between two concentric circles of these radii.

§ 65. When the component circular motions are in opposite directions, we have an extremely interesting and important case. It is obvious that there must now be positions in which OP and PQ are in the same straight

line. Let OA, AB (fig. 20) be one of these. Then, in any other position, OP and PQ are equally inclined to OA. The path of Q is an ellipse, of which the major semi-axis OB is the sum of the radii, and the minor axis their difference. Hence when the radii are equal the result is simple harmonic motion in the line OBB′ Thus we have the proposition, of very great importance in optics, that a simple harmonic motion may be looked upon as the resultant of two equal and opposite circular motions in one plane.

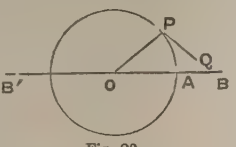

Fig. 20.

When the periods are not exactly equal, the motion may be regarded as simple harmonic motion, in a line which rotates with uniform angular velocity in a plane. This is the case of Foucault's pendulum, and of plane polarized light passing along the axis of a crystal of quartz, or through a piece of glass or other transparent substance in the magnetic field.

loids. § 66. Uniform circular motions, of different periods, give epicycloids, &c. A particular case is uniform circular motion superposed on uniform rectilinear motion, in which case we have cycloids, &c. But these we merely mention.

§ 67. By far the most important of the applications of simple harmonic analysis is summed up in what is called

rier's orem. FOURIER'S THEOREM.—*A complex harmonic function, with a constant term added, is the proper expression for any periodic single-valued function, and, consequently, can express any single-valued function whatever between any assigned values of the variable.*

To show the importance of this in physics we need take but a single example. The one essential characteristic of a musical sound is its "periodicity." Hence it may be analysed into a series of simple harmonic disturbances. Their respective periods are the fundamental period, its half, third, fourth part, &c. The first gives the pitch of the note; the others determine its quality. The investigation which follows is not intended to prove the theorem; it is merely introduced as readily suggesting it.

The essence of periodicity of a function $f$ is that we must have

$$f[x+\tfrac{1}{2}a]=f[x-\tfrac{1}{2}a]$$

whatever be $x$, provided $a$ be the period.

We may write this as

$$\varepsilon^{\frac{a}{2}\frac{d}{dx}}f(x)=\varepsilon^{-\frac{a}{2}\frac{d}{dx}}f(x),$$

or

$$\left(\varepsilon^{\frac{a}{2}\frac{d}{dx}}-\varepsilon^{-\frac{a}{2}\frac{d}{dx}}\right)f(x)=0.$$

Now the equation

$$\varepsilon^{\frac{1}{2}\xi}-\varepsilon^{-\frac{1}{2}\xi}=0$$

has the real root

$$\xi=0,$$

and the infinite series of pairs of imaginary roots

$$\tfrac{1}{2}\xi=\pm i\pi\sqrt{-1},$$

where $i$ is any integer. Hence

$$\varepsilon^{\frac{1}{2}\xi}-\varepsilon^{-\frac{1}{2}\xi}=\xi(1+\xi^2/2^2\pi^2)(1+\xi^2/4^2\pi^2)(1+\xi^2/6^2\pi^2)\ldots$$

so that the differential equation for $f(x)$ gives, besides a constant term, the infinite series of terms due to solutions of equations of the second order of which the type is

$$\left(\frac{a^2}{2^2i^2\pi^2}\left(\frac{d}{dx}\right)^2+1\right)f(x)=0.$$

The solution of this representative equation gives the following particular integral of the complete equation,

$$f(x)=P_i\cos(2i\pi xa^{-1}+Q_i).$$

Hence the general solution is

$$f(x)=A_0+\Sigma_1^\infty P_i\cos(2i\pi xa^{-1}+Q_i)$$
$$=A_0+\Sigma_1^\infty A_i\cos 2i\pi xa^{-1}+\Sigma_1^\infty B_i\sin 2i\pi xa^{-1},$$

where the constants are to be determined by special integration, according to the process already described in the article HARMONIC ANALYSIS (*q.v.*).

As a single example, suppose that the value of $f(x)$ is unity from $x=0$ to $x=a$, and zero from $x=a$ to $x=2a$. This has many applications, as, for instance, to alternate heating and cooling of one surface of a solid, alternate "make and break" with a battery and a telegraph wire, &c. In this case we have

$$f(x)=\frac{1}{2}+\frac{2}{\pi}\Sigma_1^\infty\frac{1}{2i+1}\sin\frac{(2i+1)\pi x}{a}.$$

§ 68. *A point describes a logarithmic spiral with constant angular velocity about the pole; find the acceleration.*[1] Resisted harmonic motion.

Since the angular velocity of SP (fig. 21) and the inclination of this line to the tangent are each constant, the linear velocity of P is as SP. Take a length PT, equal to $e$.SP, to represent it. Then the hodograph, the locus of $p$, where S$p$ is parallel and equal to PT, is evidently another logarithmic spiral, similar to the former, and described with the same constant angular velocity. Hence $pt$, the acceleration required, is equal to $e$.S$p$, and makes with S$p$ an angle equal to SPT. Hence, if P$u$ be drawn parallel and equal to $pt$, and $uv$ parallel to PT, the whole acceleration P$u$ may be resolved into P$v$ and $vu$; and P$vu$ is an isosceles triangle, whose base angles are each equal to the angle of the spiral. Hence P$v$ and $vu$ bear constant ratios to P$u$, and therefore also to SP or PT.

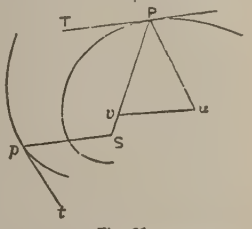

Fig. 21.

The acceleration, therefore, is composed of a central acceleration proportional to the distance, and a tangential retardation proportional to the velocity. And, if the resolved part of P's motion parallel to any line in the plane of the spiral be considered, it is obvious that in it also the acceleration will consist of two parts—one directed towards a point in the line (the projection of the pole of the spiral) and proportional to the distance from it, the other proportional to the velocity but retarding the motion. Hence a particle which, unresisted, would have a simple harmonic motion has when subject to resistance proportional to its velocity a motion represented by the resolved part of the spiral motion just described.

If $\alpha$ be the angle of the spiral, $\omega$ the angular velocity of SP, we have evidently PT. $\sin\alpha=$ SP.$\omega$.

Hence

$$Pv=Pu=pt=\frac{PT^2}{SP}=\frac{\omega}{\sin\alpha}PT=\frac{\omega^2}{\sin^2\alpha}SP=n^2.\ SP\ (\text{suppose});$$

and

$$vu=2Pv.\cos\alpha=\frac{2\omega\cos\alpha}{\sin\alpha}PT=2k.\ PT\ (\text{suppose}).$$

Thus the central acceleration at unit distance is $n^2=\omega^2/\sin^2\alpha$, and the coefficient of resistance is $2k=2\omega\cos\alpha/\sin\alpha$.

The time of oscillation is evidently $2\pi/\omega$; but, if there had been no resistance, the properties of simple harmonic motion show that it would have been $2\pi/n$; so that it is increased by the resistance in the ratio $\operatorname{cosec}\alpha : 1$, or $n:\sqrt{n^2-k^2}$.

The rate of diminution of SP is evidently

$$PT.\cos\alpha=\frac{\omega\cos\alpha}{\sin\alpha}SP=kSP;$$

that is, SP diminishes in geometrical progression as time increases, the rate being $k$ per unit of time per unit of length. By an ordinary result of arithmetic (compound interest payable every instant) the diminution of log SP in unit of time is $k$.

[1] The physical application of this problem to pendulum motion, taking place in a medium in which there is *resistance* proportional to the velocity, will be afterwards discussed analytically.

Hence, in the resolved part of the motion, the logarithm of the amplitude is diminished, every half vibration, by $k\pi/\omega$.

This process of solution is only applicable to resistance of harmonic vibrations when $n$ is greater than $k$. When $n$ is not greater than $k$ the auxiliary curve can no longer be a logarithmic spiral, for the moving particle never describes more than a finite angle about the pole; and then the geometrical method ceases to be simpler than the analytical one.

Relative motion.

§ 69. What we have said about composition of motions is merely a particular case of the general question of relative motion, which in its main principles is exceedingly simple. It is entirely comprehended in the following propositions,—which may be regarded as almost self-evident.

*Given the motion of A with regard to a point O, and that of B with regard to A, to find that of B with regard to O.*

By compounding the vectors of relative position OA, AB, we have at once the required vector OB. Thus it is obvious that we have only to add the separate components of the velocity of A with regard to O, and those of B with regard to A, to obtain those of B with regard to O. And, of course, the same rule applies to the accelerations.

If $x, y, z$ be the coordinates of A (referred to O) at time $t$; $x', y', z'$ those of B referred to parallel axes from A; $\xi, \eta, \zeta$ those of B referred to O; we have at once

$$\xi = x + x', \quad \eta = y + y', \quad \zeta = z + z'.$$

They give, by differentiation with regard to $t$,

$$\dot{\xi} = \dot{x} + \dot{x}', \text{ &c.}, \quad \ddot{\xi} = \ddot{x} + \ddot{x}', \text{ &c.},$$

which constitute the analytical proof of the statement above

§ 70. Hence we have the solution of the further question: *Given the motions of A and B with regard to O, to find the relative motion of B with regard to A.* In this case, of course, before compounding, the vector of A must have its sign changed.

Another very important case is that in which the motion is referred to axes which are themselves moving. So long as their *directions* remain unchanged, this reduces itself to the former investigation as a mere question of changed origin; so that we need consider only the effect of the change of direction of the axes. And this is at once deducible from the results of last section. For we have only to consider, instead of the moving point, its projections on the moving axes, and find *their* velocities and accelerations relative to fixed axes.

Revolving axes.

Thus, if the rectangular axes of $x$ and $y$ be fixed, and those of $\xi$ and $\eta$ be rotating in the same plane, we have a datum of the form,

$$\theta = \text{angle } \xi O x = f(t),$$

giving the position of the moving axes in terms of the time. Let P be the moving point, and PM perpendicular to $O\xi$ (fig. 22). Then, as the polar coordinates of M are $\xi$, $\theta$, we have, for its velocity,

$$\dot{\xi} \text{ along } O\xi, \quad \xi\dot{\theta} \text{ along MP}.$$

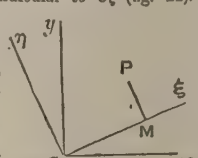

Fig. 22.

But these must be combined with the velocity of P relative to M, which consists of

$$\dot{\eta} \text{ along MP and } \eta\dot{\theta} \text{ parallel to } \xi O.$$

Thus the velocities parallel to fixed lines corresponding to the instantaneous positions of $O\xi$ and $O\eta$ are, respectively,

$$\dot{\xi} - \eta\dot{\theta} \text{ and } \dot{\eta} + \xi\dot{\theta}$$

In the same way it is easy to see, by § 47, that the corresponding components of the acceleration are

$$\ddot{\xi} - \xi\dot{\theta}^2 - \frac{1}{\eta}\frac{d}{dt}(\eta^2\dot{\theta}) \text{ and } \ddot{\eta} - \eta\dot{\theta}^2 + \frac{1}{\xi}\frac{d}{dt}(\xi^2\dot{\theta}).$$

### *Kinematics of a Rigid Plane Figure, displaced in its own Plane.*

§ 71. When a rigid plane figure is displaced anyhow in its own plane, the displacement may always be regarded as the result of a definite rotation about a definite axis perpendicular to the plane.

Motion of a plane figure in its plane.

The proof of this follows at once from the fact that, under the assigned conditions, the figure has only three degrees of freedom; and consequently its position is determinate whenever the positions of *any two* of its points are given. Also, a single rotation can, in general, be found which will transfer these two points from one pair of assigned positions to another.

Let A, B, A′, B′ (fig. 23) be successive positions of two points of the figure. Bisect AA by the line $Oa$ perpendicular to it, and let $Ob$ do the same for BB′. Let these perpendiculars meet in O. Then it is clear that the two triangles OAB, OA′B′ are similar and equal. Hence AB may be regarded as having passed to the position A′B′ by rotation about an axis through O perpendicular to the plane of the paper. The angle of rotation is AOA′ or BOB′.

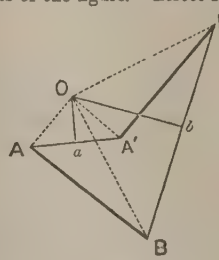

Fig. 23.

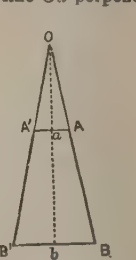

Fig. 24.

The construction fails when $Oa$ and $Ob$ coincide, but in this case it is evident that the required point O is the point of intersection of BA and B′A′ (fig. 24). It also fails when the bisecting perpendiculars are parallel (fig. 25). But then AA′ and BB′ are equal and parallel, and the displacement is a pure translation, the same for every point of the plane figure, which may be regarded as an infinitely small rotation about an infinitely distant axis.

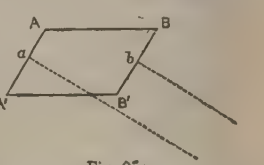

Fig. 25.

Composition of rotations about parallel axes.

§ 72. Since any displacement in one plane corresponds in general to a rotation, any two or more rotations about parallel axes can always be compounded into a single one. Of two equal and opposite rotations the resultant is simple translation. This is evident from fig. 26. In both cases A and B are the initial positions, A′ and B′ the final positions of the two axes. In the first we begin with the rotation about A, in the second with that about B.

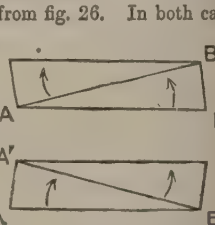

Fig. 26.

§ 73. When these equal rotations are *simultaneous* instead of *successive*, the figure becomes a rectangle; —*i.e.*, the translation is perpendicular to the line joining the axes. For in this case we may suppose the two rotations to be each broken up into successive equal but infinitesimal instalments. And the principles of infinitesimals show that two such instalments, either about the same or about different axes, produce the same ultimate effects whether they be applied simultaneously or successively. The general principle of which this is a particular case is called the "*principle of superposition of small motions.*" It is merely an application of the fact that infinitesimals of the second order may be neglected in comparison with those of the first order.

Superposition of small motions.

The consideration of simultaneous rotations is very important. Suppose a plane figure to rotate in its own plane, with angular velocity $\omega$, about the origin. Then it is obvious that $r\omega$, in a direction perpendicular to $r$, is the velocity of a point whose distance from the origin is $r$. The components are, therefore,

$$\dot{x} = -y\omega, \quad \dot{y} = x\omega .$$

If the rotation be about the point $a$, $b$, these become

$$\dot{x} = -(y-b)\omega, \quad \dot{y} = (x-a)\omega .$$

Hence, when there is any number of simultaneous rotations about parallel axes, we have

$$\dot{x} = -y\Sigma\omega + \Sigma(b\omega), \quad \dot{y} = x\Sigma\omega - \Sigma(a\omega)$$

If we write $$\Omega = \Sigma\omega ,$$

and $$\alpha = \frac{\Sigma(a\omega)}{\Sigma\omega}, \quad \beta = \frac{\Sigma(b\omega)}{\Sigma\omega} ;$$

we have $$\dot{x} = -(y-\beta)\Omega, \quad \dot{y} = (x-\alpha)\Omega .$$

These are the component velocities which the point $x$, $y$ would have if there were only a single rotation, with angular velocity $\Omega$, about an axis passing through the point $\alpha$, $\beta$.

When $$\Sigma(\omega) = \Omega = 0,$$

we see that $$\dot{x} = \Sigma(b\omega), \quad \dot{y} = -\Sigma(a\omega),$$

so that all points of the figure have equal velocities. This is the case of pure translation. Here $\alpha$ and $\beta$ are (in general) each infinite;—*i.e.*, we have as resultant a vanishing angular velocity about an infinitely distant axis.

§ 74. As any displacement of a plane figure in its own plane is equivalent to a rotation, we may represent a series of displacements by a series of rotations. Also if we know the positions, in the figure itself, of the points which are successively the axes, and likewise the position which each of them occupies in space at the instant when the rotation about it takes place, we can construct the whole motion. Let them be O, A, B, C, &c., and O, $a$, $b$, $c$, &c., respectively (fig. 27). Then the figure turns about O till A coincides with $a$. Next it turns about A (or $a$) till B coincides with $b$, and so on. Hence the motion will be represented by the *rolling* of the polygon OABC, fixed in the moving figure, on the polygon O$abc$ fixed in the plane of the motion.

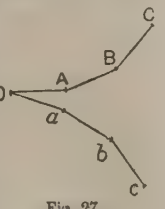

Fig. 27.

In the limit, when the axis continuously shifts its position in the figure while the rotation goes on round it, the polygons become plane curves. Thus we have the fundamental proposition that any motion of a plane figure in its own plane can be represented by the rolling of a curve attached to it, on a curve fixed in space. Both curves are situated at an infinite distance when the motion is one of pure translation.

### *Kinematics of a Rigid Figure.*

§ 75. When a spherical cap, or skin, moves on the surface of a sphere of equal radius with which it is everywhere in contact, we may make the construction of § 71 with great circles bisecting the arcs AA′ and BB′. Two great circles (unless they coincide) always intersect at the extremities of one definite diameter. The case of coincidence is met exactly as it was in § 71. Hence every motion of a spherical skin on a sphere is equivalent to a rotation about a definite axis through the centre of the sphere. Thus any number of successive or simultaneous rotations about axes passing through one point can be compounded into a single rotation about an axis passing through that point. And the construction of § 74 can be carried out with spherical polygons or curves, so that we see that any motion of a rigid figure, one point of which is fixed, can be represented by the rolling of a pyramid or cone, fixed in the figure, upon another fixed in space.

§ 76. The law of composition of simultaneous angular velocities about axes which pass through one point is precisely the same as that for simultaneous linear velocities of a moving point. The following simple geometrical process establishes the proposition for two intersecting axes; and it is easy to see that it can be extended to any number of such. Let OA and OB (fig. 28) represent the two axes, and let the lengths of these lines (both drawn in the positive direction for the rotation about them) represent the angular velocities corresponding. Then a point P, in the angle between the positive ends of the axes, is raised above the plane of the paper by rotation about OA, but depressed below it by the rotation about OB. The amounts of the elevation and depression are proportional to the distance from either axis, and to the angular velocity about it, conjointly. Hence they will annihilate one another if, perpendiculars PM, PN being drawn to the axes, we have

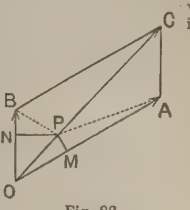

Fig. 28.

$$\text{OA} \cdot \text{PM} = \text{OB} \cdot \text{PN} .$$

This is equivalent to saying that the areas of the triangles OAP, OBP, are equal,—which necessitates that P should lie on the diagonal of the parallelogram of which OA, OB are conterminous sides. Let OC be the diagonal of this parallelogram. From what has been said above it is evident that the displacement of any point in the plane is necessarily proportional to the algebraic sum of the moments of OA and OB about it, and therefore (§ 46) to the moment of OC. Hence all points in the line OC remain at rest, and the figure turns about that line with an angular velocity represented by its length. This analogy to moments shows the reason for the remarkable proposition that angular velocities, about axes which intersect, are to be compounded according to the same law as linear velocities.

§ 77. Any proposition regarding simultaneous linear velocities or accelerations has thus its counterpart in angular velocities and accelerations. Thus, as we have seen (§ 36) that under acceleration in one plane, always perpendicular to the direction of motion, a point moves with uniform velocity, so, if a figure be rotating about one axis, and have angular acceleration about a second axis always perpendicular to the first, the *direction* of the axis about which it rotates is changed, but not the angular velocity.

It is to be noted that in such a case the direction of the axis changes not only in space, but also in the rotating figure itself. This, however, is merely the result of § 36 in a slightly altered form.

If $\omega_z$ be the angular velocity of a figure about the line which, for the moment, coincides with the axis of $z$, the consequent displacements during time $\delta t$ of a point $x$, $y$, $z$ are (§ 73)

$$\delta x = -y\omega_z\delta t, \quad \delta y = x\omega_z\delta t .$$

Of course similar results hold for the angular velocities about lines for the moment coinciding with the axes of $x$ and of $y$. The joint effect therefore is found by adding the various separate values obtained by permuting the letters $x$, $y$, $z$ in cyclical order. Thus

$$\delta x = (z\omega_y - y\omega_z)\delta t,$$
$$\delta y = (x\omega_z - z\omega_x)\delta t,$$
$$\delta z = (y\omega_x - x\omega_y)\delta t.$$

The right hand members of these equations vanish if

$$\frac{x}{\omega_x} = \frac{y}{\omega_y} = \frac{z}{\omega_z} \quad \ldots\ldots\ldots \quad (1).$$

These correspond to the two equations of the instantaneous axis, and reproduce, in an analytical form, the result of § 76.

The angular velocity about this axis is

$$\Omega = \sqrt{\omega_x^2 + \omega_y^2 + \omega_z^2} .$$

For it is clear that the direction cosines of the displacement of $x$, $y$, $z$ are proportional to

$$z\omega_y - y\omega_z, \quad x\omega_z - z\omega_x, \quad y\omega_x - x\omega_y,$$

showing that it takes place in a line perpendicular to the plan

passing through $x,y,z$ and (1). It is therefore perpendicular to (1).

Also the whole displacement is

$$\sqrt{(\delta x)^2+(\delta y)^2+(\delta z)^2}=\delta t\sqrt{(z\omega_y-y\omega_z)^2+(x\omega_z-z\omega_x)^2+(y\omega_x-x\omega_y)^2}$$

$$=\delta t\sqrt{\omega_x^2+\omega_y^2+\omega_z^2}\sqrt{x^2+y^2+z^2-\frac{(x\omega_x+y\omega_y+z\omega_z)^2}{\omega_x^2+\omega_y^2+\omega_z^2}}.$$

The last factor is the distance of $x$, $y$, $z$ from (1). Hence the second is the angular velocity about (1).

It appears at once from this result, and from the form of (1), that

$$\frac{\omega_x}{\Omega},\quad \frac{\omega_y}{\Omega},\quad \frac{\omega_z}{\Omega}$$

are the direction cosines of the instantaneous axis.

If the figure be rotating simultaneously about a number of axes, —say with angular velocity $\omega_1$, about an axis whose direction cosines are $l_1$, $m_1$, $n_1$, &c.,—we have evidently

$$\omega_x=\Sigma(l\omega),\quad \omega_y=\Sigma(m\omega),\quad \omega_z=\Sigma(n\omega).$$

From these the single instantaneous axis is found immediately as above.

Rigid figure anyhow displaced.

§ 78. Any displacement whatever of a rigid figure may be effected by means of a screw-motion, *i.e.*, translation parallel to some definite line, accompanied by a proportionate rotation about that line. Let A and A′ be successive positions of any point in the figure, and suppose the body to be brought back by a mere translation so that A′ coincides again with A. Then we have seen (§ 75) that *one* line of the figure through A is necessarily restored to its original position. Let P be any plane section of the figure, perpendicular to this line, P′ its position after displacement. These fully determine the initial and final positions of the whole figure. Shift P into the plane of P′ by a translation perpendicular to either, and let P″ be its position. P″ can (§ 71) be brought to coincide with P′ by a rotation in its own plane. Hence the proposition. There is an exceptional case when P″ requires only translation to make it coincide with P′. But then the whole figure is merely translated.

Angular accelera-tion about a moving axis.

§ 79. We have seen that the straight line representing an angular velocity is to be resolved by the same process as that representing a linear velocity. If we consider a figure to be rotating about axes fixed relatively to it, accelerations of angular velocity about these will be represented by changes in the lengths of the lines representing the angular velocities, and will therefore be subject to the same conditions as the angular velocities themselves. Thus, as it is obvious that a figure is rotating at any instant with the same angular velocity about an axis fixed relatively to itself, and about another axis *fixed in space*, which at the given instant coincides with the former, it follows that the angular accelerations about these axes are equal at that instant.

This is really the same proposition as that $\ddot{r}$ is the velocity along a fixed line coinciding with the radius-vector $r$ (§ 47). But, just as $\ddot{r}$ is not the complete acceleration parallel to $r$, if $r$ be rotating, so the proposition above, though true for the first fluxion of the angular velocity about a moving line, is not generally true for fluxions of higher orders.

As this subject is commonly regarded as somewhat obscure, we may give a more formal examination of it by an analytical process. Suppose $\omega_1$, $\omega_2$, $\omega_3$ to be the angular velocities about rectangular axes OA, OB, OC fixed relatively to a figure, and $\omega$ the angular velocity of the figure relatively to a line OS fixed in space. Let $l$, $m$, $n$, be the direction cosines of the latter line with regard to the former three, then

$$\omega=l\omega_1+m\omega_2+n\omega_3,$$

and
$$\dot{\omega}=l\dot{\omega}_1+m\dot{\omega}_2+n\dot{\omega}_3+\dot{l}\omega_1+\dot{m}\omega_2+\dot{n}\omega_3.$$

But
$$l\dot{l}+m\dot{m}+n\dot{n}=0;$$

and if, at a particular instant, we have $l=1$, $m=0$, $n=0$, this gives also $\dot{l}=0$, so that we have

$$\dot{\omega}=\dot{\omega}_1+\dot{m}\omega_2+\dot{n}\omega_3.$$

Now $m=\cos \mathrm{BOS}=\cos\theta$ suppose. Hence

$$\dot{m}=-\sin\theta.\dot{\theta}.$$

But, at the instant in question, $\theta=\frac{1}{2}\pi$ and $\dot{\theta}=\omega_3$, so that
$$\dot{m}=-\omega_3.$$

In the same way we see that

$$\dot{n}=+\omega_2;$$

and thus we have
$$\dot{\omega}=\dot{\omega}_1,$$

which is the proposition above given.

Position of rigid figure in terms of rotation about axes fixed in space;

§ 80. To complete the kinematics of a rigid figure of which one point is fixed, we require to have the means of calculating its position, after the lapse of any period during which it has been rotating with given angular velocities about given axes.

If the axes about which the angular velocities are given be fixed *in space*, the formulæ of § 77 give at once, for a unit line fixed in the figure, the expressions

$$\dot{l}=n\omega_y-m\omega_z,$$
$$\dot{m}=l\omega_z-n\omega_x,$$
$$\dot{n}=m\omega_x-l\omega_y.$$

Here $l$, $m$, $n$ are the direction cosines of the unit line at time $t$; and they satisfy, of course, the condition

$$l\dot{l}+m\dot{m}+n\dot{n}=0.$$

But, except in some special cases, these equations are intractable. This, however, is of little consequence, because in the applications to kinetics of a free rigid body the physical equations usually give the angular velocities about lines *fixed in the body*. Our problem, then, takes the form

fixed in the figure.

§ 81. *Given the angular velocities of a figure about each of a system of three rectangular axes which are rigidly attached to it, find at any time its position in space.*

It is clear that, if we know the positions of the revolving axes, referred to a fixed system, with which they at one instant coincided, the corresponding position of the figure is determined. The method usually employed is as follows.

About the common origin of the two sets of axes suppose a sphere of unit radius to be described. Let X, Y, Z (fig. 29) be the traces on this sphere of the fixed axes, and A, B, C those of the revolving axes. Draw a great circle ZC so as to meet in A′ the quadrant BA produced. Then it is clear that the figure can be constructed (*i.e.*, that the data are sufficient for calculation) if we know (*a*) the angle XZC,—this we call $\psi$; (*b*) the arc ZC, called $\theta$; (*c*) the angle A′CA, or the arc A′A, called $\phi$. For X, Y, Z are given. Then (*a*) shows how to draw the great circle ZC, whose pole is N on the great circle XY. Hence (*b*) gives us the points C and A′. We can next draw the great circle A′N, and A and B are found on it by (*c*), for $\mathrm{A'A}=\mathrm{NB}=\phi$. We have now only to determine these angular coordinates in terms of the angular velocities of the figure about OA, OB, OC, which we denote by $\omega_1$, $\omega_2$, $\omega_3$ respectively.

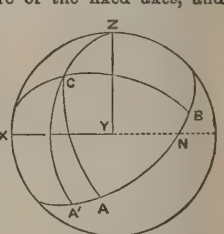

Fig. 29.

The velocity of C along ZC is $\dot{\theta}$. But it is produced by the rotations about A and B. Thus we have

$$\dot{\theta}=\omega_2\cos\phi+\omega_1\sin\phi.$$

The velocity of C perpendicular to ZC is $\sin\theta.\dot{\psi}$. This also is part of the result of the rotations about A and B, so that

$$\sin\theta.\dot{\psi}=\omega_2\sin\phi-\omega_1\cos\phi.$$

The velocity of A along AB is that of A′ together with the rate of increase of A′A. Also it is entirely due to rotation about OC. Hence

$$\cos\theta.\dot{\psi}+\dot{\phi}=\omega_3.$$

These three equations determine $\theta$, $\psi$, $\phi$ when $\omega_1$, $\omega_2$, $\omega_3$ are given as functions of $t$.

§ 82. The process above is essentially unsymmetrical. The first suggestion of a symmetrical system is due to Euler, and depends upon the general proposition of § 75. What we must seek is the single axis, and the angle of rotation about it, which (by one operation) will bring the system or figure from its initial state determined by X, Y, Z to its state at time $t$, determined by A, B, C.

Let $l$, $m$, $n$ be the direction cosines of this axis, $\varpi$ the angle of rotation about it. Then by the elementary theorems of spherical trigonometry we find

$$\cos XA = l^2 + (1-l^2)\cos\varpi,$$
$$\cos YB = m^2 + (1-m^2)\cos\varpi,$$
$$\cos ZC = n^2 + (1-n^2)\cos\varpi.$$

Thus, as we have an independent relation among $l^2$, $m^2$, $n^2$, these quantities, as well as $\varpi$, can all be expressed in terms of the cosines of the three angles between the original and final directions of the three axes severally.

We have other six equations, of which only one need be written, viz. :—

$$\cos YA = lm(1-\cos\varpi) + n\sin\varpi.$$

§ 83. If we put

$$w = \cos\tfrac{1}{2}\varpi,\ x = l\sin\tfrac{1}{2}\varpi,\ y = m\sin\tfrac{1}{2}\varpi,\ z = n\sin\tfrac{1}{2}\varpi,$$

which involve the equation of condition

$$w^2 + x^2 + y^2 + z^2 = 1,$$

the nine direction cosines of the new positions OA, OB, OC, referred to the fixed lines OX, OY, OZ, become

$$\begin{array}{lll} w^2+x^2-y^2-z^2, & 2(wz+xy), & 2(xz-wy), \\ 2(yx-wz), & w^2-x^2+y^2-z^2, & 2(yz+wx), \\ 2(xz+wy), & 2(yz-wx), & w^2-x^2-y^2+z^2. \end{array}$$

These expressions, rational in terms of the four quantities $w$, $x$, $y$, $z$, are due to Rodrigues, who, however, gave them in a slightly different form.

If $\omega_1$, $\omega_2$, $\omega_3$ be the angular velocities about OA, OB, OC, respectively, we have

$$\begin{aligned} 2\dot{w} &= -x\omega_1 - y\omega_2 - z\omega_3, \\ 2\dot{x} &= w\omega_1 - z\omega_2 + y\omega_3, \\ 2\dot{y} &= z\omega_1 + w\omega_2 - x\omega_3, \\ 2\dot{z} &= -y\omega_1 + x\omega_2 + w\omega_3. \end{aligned}$$

If $\omega_x$, $\omega_y$, $\omega_z$ be the angular velocities about OX, OY, OZ, respectively, we have

$$\begin{aligned} 2\dot{w} &= -x\omega_x - y\omega_y - z\omega_z, \\ 2\dot{x} &= w\omega_x + z\omega_y - y\omega_z, \\ 2\dot{y} &= -z\omega_x + w\omega_y + x\omega_z, \\ 2\dot{z} &= y\omega_x - x\omega_y + w\omega_z. \end{aligned}$$

Each of these sets is equivalent to three independent equations only, on account of the relation

$$w\dot{w} + x\dot{x} + y\dot{y} + z\dot{z} = 0.$$

### *Kinematics of a Deformable Figure. Strain.*

§ 84. So far we have considered change of position of a figure of invariable form. We must now consider changes of form and volume in the figure itself. This is required for application to physical problems, such as compression of a liquid or gas, the distortion of a piece of india-rubber, &c. Any such change of volume or form is called a "strain." The treatment of strains is entirely a kinematical question, until we come to regard them as produced in physical bodies, and consider their cause.

The system of forces which is said to produce a strain is called a "stress." But, just as we study velocity as a preparation for the discussion of the effect of force on a free body, so we study strains as a preparation for the discussion of the effects of stress.

§ 85. In order to fix the ideas, it is convenient to suppose the figure which is to undergo strain to be cut up into an infinite number of similar, equal, and similarly situated parellelepipeds. This is effected at once by supposing it to be cut by three series of planes, those of each series being parallel to one another, and equidistant. No two of these three series must be parallel, but the distance from plane to plane need not be the same in any two of the series. If the strain be *continuous* there will be no finite difference of effect upon any two neighbouring parallelepipeds;—but in general their edges, which originally formed three series of parallel straight lines, will become series of curves. No two parallelepipeds of the system will in general be altered in precisely the same manner. This is called "heterogeneous strain."

§ 86. We found it convenient to study uniform speed before proceeding to consider variable speed, and so we find it convenient to take up first what is called Homogeneous strain.

*Homogeneous Strain.*—A figure is said to be homogeneously strained when all parts of it originally equal, similar, and similarly situated remain equal, similar, and similarly situated, however much they may individually have been altered in form, volume, and position.

Now recur to our set of parallelepipeds. After a homogeneous strain these remain equal, similar, and similarly situated. Hence *they must remain parallelepipeds*, for they must together still continuously make up the volume of the altered figure. Thus planes remain planes, and straight lines remain straight lines. Equal parallel straight lines remain equal and parallel. Parallel planes remain parallel, ellipses remain ellipses (as is obvious from their properties relative to conjugate diameters), ellipsoids remain ellipsoids, &c.

But we can now easily see how many conditions fully determine a homogeneous strain. For if we know how each of three conterminous edges of any one of the original parallelepipeds is altered in length and direction, we can build up the whole altered system. Hence, to fully describe a homogeneous strain, we require merely to know what changes take place in the lengths and directions of three unit lines not in one plane. Three numbers are required for the altered lengths, and two (analogous, say, to altitude and azimuth, or latitude and longitude, or R.A. and N.P.D.) for each of the altered directions. Hence, in general, a homogeneous strain depends upon, and is fully characterized by, *nine* independent numbers. require nine constants.

§ 87. The simplest form of strain is that which is due to uniform hydrostatic stress acting on a homogeneous isotropic body. Here directions remain unaltered, and the lengths of all lines are altered in the same ratio. Every portion of the original figure remains similar to itself, its linear, superficial, and volume dimensions being altered as the first, second, and third powers of that ratio. Uniform dilatation.

Next in order of simplicity is the case in which there are three directions, at right angles to one another, which suffer no change except as regards *length*. This state of things would be produced in a homogeneous isotropic body by three longitudinal extensions or compressions in lines at right angles to one another, or by hydrostatic pressure in a homogeneous non-isotropic solid. In this case, if the changes of length above spoken of are all different, an originally spherical figure becomes an ellipsoid, with three unequal axes parallel respectively to the lines whose directions remain unaltered. Every line in the body not originally parallel to one of these is altered in direction. If one of the principal changes of length be an extension, and another a shortening, there will be a cone formed of lines which are not altered in length. This is seen at once by describing from the centre of the ellipsoid a sphere equal to the original sphere. One axis of the ellipsoid being greater than the radius of the sphere, and another less, the ellipsoid and sphere must intersect; and all lines drawn from the common centre to the curve of intersection are unaltered in length (though all altered, as before remarked, in direction). Pure strain.

Pure strain.

When two only of the changes of length are equal, the ellipsoid becomes one of rotation, oblate or prolate as the case may be; and if the radius of the sphere be intermediate in value to the axes of this rotation-ellipsoid, we have a *right* cone of rays unaltered in length.

When all three changes of length are equal we have the simplest possible case,—which has been already treated.

§ 88. The essential element in these particular cases is that three lines at right angles to one another are unaltered in direction by the strain. Here there is a mere change of form, and the strain is said to be "pure," or "free from rotation." Such a strain, in its most general form, is fully characterised by *six* independent numbers. For a system of three mutually perpendicular lines is fully given in direction by *three* numbers, and three more are required for the changes of length which they severally undergo.

Rotational strain.

Strain ellipsoid.

But, in general, a strain is not pure. It will be shown, however, below that the principal axes of the ellipsoid into which a sphere is changed by any strain, and which is called the "strain ellipsoid," were originally radii of the sphere at *right* angles to one another. Hence the strain may be looked upon as made up of two operations, viz., a pure strain, and a rotation through a definite angle about an axis in a definite position in space. The axes of the pure strain are lines fixed in the figure.

Conjugate of a strain.

§ 89. It is useful, in farther considering the subject, to introduce along with the original strain (thus analysed), another which is called its "conjugate." This is defined as composed of an equal pure strain with the first with an equal but opposite rotation. And the separate component operations must be taken in the opposite order in the strain and in its conjugate.

The successive application of the strain and its conjugate thus necessarily leads to the reduplication (or squaring) of the pure part of the strain, and to the annihilation of the rotation. For, call the parts, as operators, P and R. The strain and its conjugate, referred to axes fixed in space, may be either

$$RP \text{ and } PR^{-1}$$

or

$$P_1R \text{ and } R^{-1}P_1,$$

according as the pure strain or the rotation is first applied. The operations in each group are written, from right to left, in the order in which they are performed. Thus RP means the pure strain P, followed by the rotation R.

Successive application of conjugate strains.

§ 90. The final results are $P^2$ and $P_1^2$. In the first case we have the pure strain, followed by the rotation; then (by the conjugate) the rotation is undone, and the pure strain reapplied. In the second we rotate first, then apply the pure strain twice, and finally undo the rotation. Thus the student must be cautioned against the error of supposing that the results of applying PR and RP separately are generally the same. Perhaps it will be easier for the

Reciprocal strain.

reader to consider the "reciprocal," instead of the conjugate, of a strain. For if the strain be RP, the reciprocal is obviously $P^{-1}R^{-1}$; if it be PR, the reciprocal is $R^{-1}P^{-1}$. Either pair of these, taken in either order, restores the figure to its primitive form. The one point to be noticed is that, in whatever order the direct component operations are supposed to occur in the strain, their reciprocals must be taken in the opposite order in the reciprocal strain. The reciprocal strain simply undoes the strain, and therefore differs from the conjugate by a factor, the square of the pure part of the strain.

From this we have at once, as will be seen later, the means of decomposing a given strain into its pure and its rotational factors. This is effected as soon as we can form the expression for the conjugate strain in terms of that for the strain itself.

§ 91. As, in general, any strain converts a spherical portion of a figure into an ellipsoid, and as an ellipsoid has two series of parallel *circular sections*, it appears that in every strain there are two series of *planes of no distortion*.[1] The consideration of these planes leads us to a second and very different mode of analysing a strain into simpler components. Perhaps the most elementary mode of considering this subject is by thinking of the motion of water flowing slowly down a uniform channel. We know that water, at ordinary pressures, is practically incompressible; also that the upper layers of the water in a canal flow faster than those below them. Hence the definition of a "simple shear." Let one plane of a figure be fixed, and let the various planes parallel to it slide over it and over one another, all in the same direction, and with velocities proportional to their distances from the fixed plane. It is clear that this shear produces homogeneous strain in the figure, but it is mere change of form without change of volume. The fixed plane and all those parallel to it, are planes of no distortion. But we have seen that there must be two sets of such planes. To find the second set, let us suppose the plane of fig. 30 to be parallel to the common direction of sliding, and perpendicular to the fixed plane. This plane, so defined, is the plane of the shear. Let AB be the trace on it of the fixed plane, PQ that of one of the sliding planes, PP′ the amount of its sliding. Bisect PP′ in M by a perpendicular, meeting AB in A. Join AP, take AB = AP, and draw BQ parallel to AP. Consider the strain of the rhomboidal portion APQB of the figure. P moves to P′, and Q to Q′, where QQ′ = PP′. Hence the rhombus remains a rhombus, for AP′ = AP = AB. But the lengths of its diagonals have been interchanged. It has been subjected to an elongation of AQ, and a contraction of BP, each in the same ratio (so that their product, *i.e.*, double the area of the rhombus, remains unaltered), while all lines perpendicular to the plane of the figure remain unaltered. From the symmetry of the rhombus it is obvious that AQ′ and BP′ are the greatest and least axes of the strain ellipsoid, while AB and AP′ are parallel to its circular sections. Planes originally parallel to AP and perpendicular to the paper are therefore the second set of planes of no distortion. The rotational part of the shear may be measured in terms of the angle PAM, but is given directly by PBP′, and its axis is perpendicular to the plane of the figure. The most convenient measure of the shear is the ratio of PP′ to AM, or, what involves the same, the angle PAP′. Another mode of measuring it is by means of the ratio BP/AQ, $= 1 + e$, suppose. If $e$ be a small quantity, as is usually the case with solids, we may write $1 \doteq e$ for the measure of the shear. Here $e$ indicates the extension per unit of length along one diagonal of the rhombus, and the contraction per unit of length along the other.

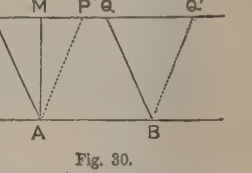

Fig. 30.

Decomposition of a strain.

§ 92. It is quite clear from what has been said that we can analyse a strain by the help of simple shears compounded with different forms of pure strain. For the shears may be taken in an infinite number of ways so as to produce the rotational part of the given strain, while also producing deformation without change of volume. The final adjustment is to be made by a pure strain, whose axes are those of the strain ellipsoid due to the shears. As a shear depends on four quantities only, two shears and a dilatation furnish the nine constants required for a homogeneous strain.

[1] We here exclude spheres and ellipsoids of rotation. The latter have only one series of circular sections, the former an infinite number.

Composition of pure strains.

**The successive application of two pure strains does not, except in special cases, give rise to a pure strain. This is, physically, a most important proposition. Thus, for instance, the instantaneous strains of each element of a perfect fluid in which there is no vortex motion are pure; and yet, if the element be followed in its motion, it will be found in general to rotate. Its motion is said to be "differentially irrotational."**

To prove this proposition by the help of a particular case is simple enough. Take, for instance, a compression in one direction, followed by an equal extension in a different direction. Only when these directions are at right angles to one another is the resultant strain pure.

Analysis.

§ 93. The analytical theory of strains is, at least in its elements, an immediate application of the properties of determinants, usually of the third order. We subjoin a slight sketch of it.

We have seen that it is only necessary, for the full characterizing of a strain, that we should know what becomes of three unit lines not originally coplanar. Take these parallel to the axes (generally oblique) of $x, y, z$. Then if the $x$ unit becomes a line which is the diagonal of a parallelepiped with sides $a, d, g$ parallel to the axes, $y$ similarly that of $b, e, h$, and $z$ of $c, f, i$, we see at once that the coordinates of the point originally at $x, y, z$ become

$$\left.\begin{aligned} x' &= ax + by + cz \\ y' &= dx + ey + fz \\ z' &= gx + hy + iz \end{aligned}\right\} \quad \ldots\ldots\ldots \text{(A)}.$$

Here it is obvious, from the premises, that the nine quantities $a, b, c$; $d, e, f$; $g, h, i$ are all real, and altogether independent, at least so far as kinematics is concerned.[1] To obtain an idea of their nature from another point of view, let us suppose the axes to be rectangular. Let unit parallel to $x$ become $e_1$, in the direction given by the cosines $l_1, m_1, n_1$. Similarly, let $e_2$, $l_2, m_2, n_2$ belong to a unit originally parallel to $y$, and $e_3$, $l_3, m_3, n_3$ to a unit parallel to $z$. Then the broken line $x, y, z$ becomes $x', y', z'$, where

$$\left.\begin{aligned} x' &= e_1 l_1 x + e_2 l_2 y + e_3 l_3 z \\ y' &= e_1 m_1 x + e_2 m_2 y + e_3 m_3 z \\ z' &= e_1 n_1 x + e_2 n_2 y + e_3 n_3 z \end{aligned}\right\} \quad \ldots\ldots \text{(A')}.$$

Though we have introduced three numbers $e$ along with nine direction cosines, no greater generality is secured, for there are three necessary relations, one among each set of cosines.

Characteristic of pure strain.

To find the characteristic property of a pure strain, let us take it in its most general form. Thus let $l_1, m_1, n_1$ *now* denote a line which, without change of direction, has its length altered by the strain in the ratio $e_1 : 1$. Let $l_2, m_2, n_2$, $e_2$ and $l_3, m_3, n_3, e_3$ be similar data for the other two of the system of rectangular axes of the pure strain. Then to *these* axes the coordinates of $x, y, z$ are

$$\begin{aligned} \xi &= l_1 x + m_1 y + n_1 z, \\ \eta &= l_2 x + m_2 y + n_2 z, \\ \zeta &= l_3 x + m_3 y + n_3 z. \end{aligned}$$

The strain converts $\xi$ into $\xi' = e_1 \xi$, $\eta$ into $\eta' = e_2 \eta$, and $\zeta$ into $\zeta' = e_3 \zeta$. Hence the final coordinates (to the original axes) of the point originally at $x, y, z$ are

$$\begin{aligned} x' &= l_1 \xi' + l_2 \eta' + l_3 \zeta', \\ y' &= m_1 \xi' + m_2 \eta' + m_3 \zeta', \\ z' &= n_1 \xi' + n_2 \eta' + n_3 \zeta'; \end{aligned}$$

or, in terms of $x, y, z$,

$$\left.\begin{aligned} x' &= (e_1 l_1^2 + e_2 l_2^2 + e_3 l_3^2)x + (e_1 l_1 m_1 + e_2 l_2 m_2 + e_3 l_3 m_3)y \\ &\quad + (e_1 l_1 n_1 + e_2 l_2 n_2 + e_3 l_3 n_3)z \\ y' &= (e_1 m_1 l_1 + e_2 m_2 l_2 + e_3 m_3 l_3)x + (e_1 m_1^2 + e_2 m_2^2 + e_3 m_3^2)y \\ &\quad + (e_1 m_1 n_1 + e_2 m_2 n_2 + e_3 m_3 n_3)z \\ z' &= (e_1 n_1 l_1 + e_2 n_2 l_2 + e_3 n_3 l_3)x + (e_1 n_1 m_1 + e_2 n_2 m_2 + e_3 n_3 m_3)y \\ &\quad + (e_1 n_1^2 + e_2 n_2^2 + e_3 n_3^2)z \end{aligned}\right\} \quad \text{(B)}.$$

If we compare this with the general expression above given for a strain, we see that the coefficient of $y$ in the value of $x'$ is *equal* to that of $x$ in the value of $y'$. Similarly that of $z$ in $x'$ is equal to that of $x$ in $z'$; and that of $z$ in $y'$ is equal to that of $y$ in $z'$; or finally

$$b = d, \quad c = g, \quad f = h.$$

[1] But when strain is produced in a piece of *matter*, a limitation comes in. For, to take the simplest case, the strain

$$x' = -x, \quad y' = -y, \quad z' = -z$$

implies that the figure to which it is applied has been "perverted,"—*i.e.*, changed into its image as seen in a plane mirror.

Conversely, when these three conditions are satisfied, and not otherwise, the strain is pure. It is to be observed that $\xi, \eta, \zeta$ form a rectangular system, and thus the nine direction cosines (usually involving *six* arbitrary numbers) depend here on three numbers alone. Thus there are six independent numbers, corresponding to $a, e, i, b, c, f$, in the general expression for the strain.

Pure strain depends on six conditions.

It is clear, from the elements of coordinate geometry, that the determinant

$$\begin{vmatrix} a & b & c \\ d & e & f \\ g & h & i \end{vmatrix}$$

represents the ratio in which the volume is increased by the strain.[2]

Change of volume by strain.

Let us now introduce, in succession to the strain

$$\begin{matrix} a & b & c \\ d & e & f \\ g & h & i \end{matrix} \quad \ldots\ldots\ldots \text{(1)},$$

Conjugate strains.

the connected strain

$$\begin{matrix} a & d & g \\ b & e & h \\ c & f & i \end{matrix} \quad \ldots\ldots\ldots \text{(1')},$$

which obviously produces an equal change of volume with the former.

Applying these strains in succession, we have as the final result

$$\begin{aligned} x'' &= ax' + dy' + gz', \\ y'' &= bx' + ey' + hz', \\ z'' &= cx' + fy' + iz', \end{aligned}$$

or, substituting for $x', y', z'$ their values in terms of $x, y, z$,

$$\begin{aligned} x'' &= (a^2 + d^2 + g^2)x + (ab + de + gh)y + (ac + df + gi)z, \\ y'' &= (ba + ed + hg)x + (b^2 + e^2 + h^2)y + (bc + ef + hi)z, \\ z'' &= (ca + fd + ig)x + (cb + fe + ih)y + (c^2 + f^2 + i^2)z. \end{aligned}$$

Thus the resultant strain is

$$\begin{matrix} a^2 + d^2 + g^2 & ab + de + gh & ac + df + gi \\ ba + ed + hg & b^2 + e^2 + h^2 & bc + ef + hi \\ ca + fd + ig & cb + fe + ih & c^2 + f^2 + i^2 \end{matrix}$$

which, for simplicity, we will write as

$$\begin{matrix} \alpha & \delta & \gamma \\ \delta & \epsilon & \beta \\ \gamma & \beta & \iota \end{matrix} \quad \ldots\ldots\ldots \text{(2)}.$$

It will be observed that this group of nine numbers, if treated as a determinant, constitutes the product of the determinants formed of the two systems above.

This satisfies the criterion of a "pure strain," as given above; and we thus see that in the successive application of the strains

$$\begin{matrix} a & b & c \\ d & e & f \\ g & h & i \end{matrix} \quad \text{and} \quad \begin{matrix} a & d & g \\ b & e & h \\ c & f & i \end{matrix}$$

the rotation produced by the first is annihilated by the second.

Let A, B, C, &c., be the minors of

$$\Delta = \begin{vmatrix} a & b & c \\ d & e & f \\ g & h & i \end{vmatrix}$$

corresponding to $a, b, c$, &c.

Then by our original equations we have

$$\begin{aligned} \Delta x &= Ax' + Dy' + Gz', \\ \Delta y &= Bx' + Ey' + Hz', \\ \Delta z &= Cx' + Fy' + Iz'. \end{aligned}$$

Thus the reciprocal of the strain

$$\begin{matrix} a & b & c \\ d & e & f \\ g & h & i \end{matrix} \quad \text{is} \quad \begin{matrix} A/\Delta & D/\Delta & G/\Delta \\ B/\Delta & E/\Delta & H/\Delta \\ C/\Delta & F/\Delta & I/\Delta. \end{matrix}$$

Reciprocal of strain.

This is evident from the formulæ just written. For they express that the new strain converts $x', y', z'$ into $x, y, z$.

Apply the resultant strain in succession to this reciprocal. The result is easily foreseen from separate terms like the following:—

$$\begin{aligned} &A(a^2 + d^2 + g^2) + B(ab + de + gh) + C(ac + df + gi) \\ &\quad = a(Aa + Bb + Cc) + d(Ad + Be + Cf) + g(Ag + Bh + Ci) \\ &\quad = a\Delta; \text{ &c.} \end{aligned}$$

[2] When this strain is produced in a piece of *matter*, the numerical value of the determinant obviously cannot be *negative*.

Hence when we apply (2) to a figure previously strained by the reciprocal of (1) the result is the strain (1′). Hence we verify that the latter is the conjugate of (1); as it possesses the properties described in § 90, all of which are thus established.

Analysis of strain.

To analyse a strain in the simplest manner, we must find the axes of the strain ellipsoid (§ 88), as well as the original radii of the unit sphere which were distorted into them. It is more direct, however, to consider the ellipsoid which becomes a unit sphere in consequence of the strain. The equation of that ellipsoid is

$$(ax+by+cz)^2+(dx+ey+fz)^2+(gx+hy+iz)^2=1;$$

or, with the notation employed in (2) above,

$$ax^2+\epsilon y^2+\iota z^2+2\delta xy+2\beta yz+2\gamma zx=1.$$

But the square of any radius-vector is

$$x^2+y^2+z^2=r^2, \text{ suppose.}$$

The maximum radius-vector, therefore, of the ellipsoid is found from the two equations

$$(ax+\delta y+\gamma z)dx+(\delta x+\epsilon y+\beta z)dy+(\gamma x+\beta y+\iota z)dz=0,$$
$$xdx+ydy+zdz=0.$$

Hence, $p$ being a numerical quantity to be found,

$$\left.\begin{aligned} ax+\delta y+\gamma z&=px,\\ \delta x+\epsilon y+\beta z&=py,\\ \gamma x+\beta y+\iota z&=pz. \end{aligned}\right\} \quad \ldots\ldots\ldots \quad (4).$$

Multiply respectively by $x$, $y$, $z$, add, and take account of the two preceding undifferentiated equations. We thus have

$$1=pr^2,$$

or $p$ is the reciprocal of the square of the maximum semi-axis required.

But, if we eliminate $x$, $y$, and $z$ simultaneously from the preceding linear equations, we have

$$\begin{vmatrix} a-p & \delta & \gamma \\ \delta & \epsilon-p & \beta \\ \gamma & \beta & \iota-p \end{vmatrix}=0.$$

Axes of the strain ellipsoid.

This equation is known to have three real positive roots, because the determinant is symmetrical. The roots are the squared reciprocals of the semi-axes of the ellipsoid, *i.e.*, they are the squares of the semi-axes of the strain ellipsoid.

When the three values of $p$ have been found from this equation, any two of the equations (4) give in an unambiguous form the corresponding values of the ratios $x:y:z$ for each of them. Thus we know the original positions of the lines which become the axes of the strain ellipsoid. Their final positions are found from these by means of (A). And, since we thus know the original and final positions of the rectangular system, the method of Rodrigues enables us to calculate the axis and amount of the rotation.

One line, at least, unaltered in direction.

In homogeneous strain, one direction at least is unchanged. This is an addition to, or extension of, the singular result of § 75. For, if $x$, $y$, $z$ be shifted to a point on its radius-vector, we must have

$$\left.\begin{aligned} ax+by+cz&=\epsilon x\\ dx+ey+fz&=\epsilon y\\ gx+hy+iz&=\epsilon z \end{aligned}\right\};$$

so that

$$\begin{vmatrix} a-\epsilon & b & c \\ d & e-\epsilon & f \\ g & h & i-\epsilon \end{vmatrix}=0,$$

a cubic equation, which must have one real root.

Strain a mere rotation.

When the figure is rigid, the strain must be a rotation only. Hence in the formulæ (A′) above we have $e_1=e_2=e_3=1$. Thus the last written equation becomes

$$\begin{vmatrix} l_1-\epsilon & l_2 & l_3 \\ m_1 & m_2-\epsilon & m_3 \\ n_1 & n_2 & n_3-\epsilon \end{vmatrix}=0;$$

or (by the properties of the direction cosines of a set of rectangular axes)

$$1-(l_1+m_2+n_3)(\epsilon-\epsilon^2)-\epsilon^3=0.$$

This has, of course, the real root $\epsilon=1$. But we also have

$$1+\epsilon(1-(l_1+m_2+n_3))+\epsilon^2=0.$$

This cannot have real roots if the coefficient of $\epsilon$ lie between the limits 2 or −2. But these are its greatest and its least possible values. For, first, $l_1$, $m_2$, $n_3$ may be each = 1 simultaneously. Here we have

$$(1-\epsilon)^2=0.$$

Or two of them may be each = −1, but then (to avoid perversion) the third must be = 1. Then we have

$$(1+\epsilon)^2=0.$$

In the first case the figure has no rotation. In the second it rotates through an angle $\pi$ about the axis of $\epsilon=1$.

Composition of two pure strains.

The proposition that two pure strains succeeding one another usually give a rotational strain is proved at once by analysis. Let the pure strains be such that

$$\left.\begin{aligned} x'&=ax+dy+cz,\\ y'&=dx+ey+bz,\\ z'&=cx+by+iz; \end{aligned}\right.$$

and

$$\left.\begin{aligned} x''&=a'x'+d'y'+c'z',\\ y''&=d'x'+e'y'+b'z',\\ z''&=c'x'+b'y'+i'z'. \end{aligned}\right.$$

Then, writing only the second term of $x''$ and the first of $y''$ in terms of $x$, $y$, $z$, we have

$$\left.\begin{aligned} x''&=\ \ldots\ldots\ +(a'd+d'e+c'b)y+\ \ldots\\ y''&=(a'a+c'd+b'c)x+\ \ldots\ldots\ +\ \ldots\\ z''&=\ \ldots\ldots\ +\ \ldots\ldots\ +\ \ldots \end{aligned}\right.$$

It is clear that, in general, this is *not* a pure strain. But it is also clear that a third pure strain can be found whose application in succession to the other two will give a pure strain.

For let the last equations be written

$$\left.\begin{aligned} x''&=a''x+b''y+c''z,\\ y''&=d''x+e''y+f''z,\\ z''&=g''x+h''y+i''z; \end{aligned}\right.$$

and let us apply further the pure strain

$$\left.\begin{aligned} x'''&=\alpha x''+\delta y''+\gamma z'',\\ y'''&=\delta x''+\epsilon y''+\beta z'',\\ z'''&=\gamma x''+\beta y''+\iota z''. \end{aligned}\right.$$

Then we have

$$\left.\begin{aligned} x'''&=\ \ldots\ldots\ +(\alpha b''+\delta e''+\gamma h'')y+\ \ldots\\ y'''&=(\delta a''+\epsilon d''+\beta g'')x+\ \ldots\ldots\ +\ \ldots\\ z'''&=\ \ldots \end{aligned}\right.$$

There are but three conditions to satisfy, that this strain may be pure. But we may accomplish this in an infinite number of ways, for we have five disposable quantities, viz., the ratios of any five of $\alpha$, $\epsilon$, $\iota$, $\beta$, $\gamma$, $\delta$ to the remaining one. In a precisely similar manner we may show that three pure strains can be found, such that their resultant is a mere rotation. In fact, all we have to do, since two pure strains in general produce a distortion accompanied by rotation, is to apply a pure strain to annihilate the distortion, which can of course always be done.

Heterogeneous strain.

§ 94. In general when a figure is continuously strained, which is usually the case in physical applications, at least until cracks occur, the strain is not homogeneous. But, on account of the continuity of the strain, portions indefinitely near one another are strained indefinitely nearly alike. Hence we may treat such a case by the ordinary process for homogeneous strain, so long as we confine our attention to small regions of the figure strained. When there is discontinuity in the motion of a fluid, it is the common practice to treat the motion as continuous by the fiction of an infinitely thin vortex-sheet separating the two discontinuously moving portions. This is, in all likelihood, physically true in ordinary fluids; but, so far as the imaginary frictionless fluid of the mathematicians is concerned, it is a mere analytical artifice to enable us to carry out the investigation. See ATOM and HYDROMECHANICS, in which the mathematical theory of "vortex motion" is very fully considered.

Displacements of system of points.

Suppose space to be uniformly occupied by points which are displaced in a continuous manner. Let $\xi$, $\eta$, $\zeta$ be the rectangular components of the displacement of a point originally situated at $x$, $y$, $z$. The continuity of the displacement requires merely that the differential coefficients, of all orders, of $\xi$, $\eta$, $\zeta$, with respect to $x$, $y$, $z$ (and any combination of them) shall be *finite*. That being assumed, the displacement, parallel to $x$, of the point whose initial coordinates were $x+\delta x$, $y+\delta y$, $z+\delta z$ (where $\delta x$, $\delta y$, $\delta z$ are indefinitely small quantities of the first order) is necessarily expressed by

$$\xi+\frac{d\xi}{dx}\delta x+\frac{d\xi}{dy}\delta y+\frac{d\xi}{dz}\delta z.$$

Hence the relative coordinate of the second point with regard to the first is changed from $\delta x$ to $\delta x+\frac{d\xi}{dx}\delta x+\frac{d\xi}{dy}\delta y+\frac{d\xi}{ds}\delta z$. And

onstants f the onse- nent rain.

similarly for the other relative coordinates. Hence the strain in the immediate vicinity of the point $x, y, z$ is given by

$$\begin{matrix} 1+\frac{d\xi}{dx} & \frac{d\xi}{dy} & \frac{d\xi}{dz} \\ \frac{d\eta}{dx} & 1+\frac{d\eta}{dy} & \frac{d\eta}{dz} \\ \frac{d\zeta}{dx} & \frac{d\zeta}{dy} & 1+\frac{d\zeta}{dz} \end{matrix}.$$

If the differential coefficients are all small quantities, whose squares and products two and two may be neglected, *i.e.*, if the strain is slight, we have for the ratio in which the volume is increased

$$1+\frac{d\xi}{dx}+\frac{d\eta}{dy}+\frac{d\zeta}{dz} : 1.$$

Condi- tion hat olume s un- ltered.

Hence the condition of no change of volume is

$$\frac{d\xi}{dx}+\frac{d\eta}{dy}+\frac{d\zeta}{dz}=0.$$

To examine this case more closely, let us suppose that it consists of a pure strain as in § 93 (B), superposed on a rotation $\omega_x, \omega_y, \omega_z$ about the axes of $x, y$, and $z$ as in § 77. Let these be so small as not to interfere with one another. That compound strain would be

$$\begin{matrix} e_1l_1^2+e_2l_2^2+e_3l_3^2 & e_1l_1m_1+e_2l_2m_2+e_3l_3m_3-\omega_z & e_1l_1n_1+\ldots+\omega_y \\ e_1m_1l_1+e_2m_2l_2+e_3m_3l_3+\omega_z & e_1m_1^2+e_2m_2^2+e_3m_3^2 & e_3m_1n_1+\ldots-\omega_x \\ e_1n_1l_1+e_2n_2l_2+e_3n_3l_3-\omega_y & e_1n_1m_1+\ldots\ldots\ldots+\omega_x & e_1n_1^2+e_2n_2^2+e_4n_3^2. \end{matrix}$$

Comparing with the above, we find

$$1+\frac{d\xi}{dx}=e_1l_1^2+e_2l_2^2+e_3l_3^2,$$

or, if we put $\epsilon$ for the "elongation," so that $e=1+\epsilon$,

$$\frac{d\xi}{dx}=e_1l_1^2+e_2l_2^2+e_3l_3^2,$$

with similar expressions for $\frac{d\eta}{dy}$ and $\frac{d\zeta}{dz}$.

These give

$$\frac{d\xi}{dx}+\frac{d\eta}{dy}+\frac{d\zeta}{dz}=e_1+e_2+e_3.$$

Again we have

$$\begin{aligned} \frac{d\eta}{dx}+\frac{d\xi}{dy} &= 2(e_1l_1m_1+e_2l_2m_2+e_3l_3m_3), \\ &= 2(e_1l_1m_1+e_2l_2m_2+e_3l_3m_3), \end{aligned}$$

with other two of the same kind.

Deter- mina- tion of the rota- tions.

Also we have three equations of the form

$$\left.\begin{aligned} 2\omega_x &= \frac{d\zeta}{dy}-\frac{d\eta}{dz} \\ 2\omega_y &= \frac{d\xi}{dz}-\frac{d\zeta}{dx} \\ 2\omega_z &= \frac{d\eta}{dx}-\frac{d\xi}{dy} \end{aligned}\right\}.$$

Condition f no otation.

These expressions show, simply, that when there is no elementary rotation the quantity

$$\xi dx+\eta dy+\zeta dz=d\phi$$

is the complete differential of a function of three independent variables. If we combine the condition that there shall be no change of volume with those that there shall be no rotation, we can eliminate $\xi, \eta, \zeta$; and we arrive at Laplace's equation

$$\frac{d^2\phi}{dx^2}+\frac{d^2\phi}{dy^2}+\frac{d^2\phi}{dz^2}=0.$$

This shows at once how a graphical representation of stationary distributions of temperature, electric potential, &c., may be given by means of a strain.

If $dS$ be an element of a surface at the point $x, y, z$, and $l, m, n$ the direction cosines of its normal, the rotation about the normal is obviously

$$l\omega_x+m\omega_y+n\omega_z$$

The integral of double of this over a finite portion of surface is

$$\iint dS\left(l\left(\frac{d\zeta}{dy}-\frac{d\eta}{dz}\right)+m\left(\frac{d\xi}{dz}-\frac{d\zeta}{dx}\right)+n\left(\frac{d\eta}{dx}-\frac{d\xi}{dy}\right)\right),$$

or

$$\iint\left\{\left(\frac{d\zeta}{dy}-\frac{d\eta}{dz}\right)dydz+\left(\frac{d\xi}{dz}-\frac{d\zeta}{dx}\right)dzdx+\left(\frac{d\eta}{dx}-\frac{d\xi}{dy}\right)dxdy\right\}.$$

This, as seems to have been first pointed out by Stokes, can be expressed as a simple integral in the form

$$\int(\xi dx+\eta dy+\zeta dz)$$

extended round the boundary of the surface. Hence the double integral has the same value for all finite surfaces having the same boundary; and, as a consequence, it vanishes when taken over a closed simply-connected surface. Hence we see at once that it vanishes for multiply-connected surfaces also. The proof of the equality of the single and double integral has only to be established for a mere surface element. For, when that is done, the common boundary of each pair of elements gives equal portions, with opposite signs, in the single integral.

So-called equation of con- tinuity.

Directly connected with the displacements of a group of points, we have the question, *What is the mathematical expression of the fact that the number of points is not altered?* There are many ways of answering this; but the following, which is immediately deducible from our recent investigation, seems sufficiently simple. If $l, m, n$ be the direction cosines of the normal to an element $dS$ of a singly-connected closed surface, the number of points which pass through the element in the time $\delta t$ in consequence of the displacement $\xi\delta t, \eta\delta t, \zeta\delta t$ at the point $x, y, z$ is

$$(l\xi+m\eta+n\zeta)\rho dS\delta t,$$

where $\rho$ is the number of points per unit volume at $x, y, z$. But at every point inside the closed surface the density is altered from $\rho$ to $\rho+\dot{\rho}\delta t$. It will be noticed that $\xi, \eta, \zeta$ now stand for the $x, y, z$ components of velocity.

Hence, if the excess of the number of points passing into the surface over those escaping be equated to the increase of the number of points included in the closed space, which is calculated from the change of density inside, we have

$$\delta t\iint(l\xi+m\eta+n\zeta)\rho dS=\delta t\iiint\dot{\rho}dxdydz.$$

If we take for S an elementary rectangular parallelepiped, with edges $\delta x, \delta y, \delta z$, this becomes at once

$$-\left(\frac{d(\rho\xi)}{dx}+\frac{d(\rho\eta)}{dy}+\frac{d(\rho\zeta)}{dz}\right)\delta x\delta y\delta z\delta t=\dot{\rho}\delta x\delta y\delta z\delta t$$

or

$$\frac{d\rho}{dt}+\frac{d(\rho\xi)}{dx}+\frac{d(\rho\eta)}{dy}+\frac{d(\rho\zeta)}{dz}=0.$$

If the arrangement is incompressible this becomes, as above,

$$\frac{d\xi}{dx}+\frac{d\eta}{dy}+\frac{d\zeta}{dz}=0.$$

In any one of the last four forms the expression is called the "equation of continuity," another of the preposterously ill-chosen terms which have been introduced with only too great success into the nomenclature of our subject.

Changes of figure of a jointed system of rigid

§ 95. In the strains which we have hitherto considered all parts of a figure were regarded as capable of changing their form and volume; and the strain of any element, when not identical with that of a proximate element, was supposed to differ only infinitesimally from it. But there is another class of changes of form, for which this restriction does not hold. The most important case, and the only one we can here consider, is that of "link-work." Here each finite piece is treated as incapable of change of form, and the change of form of the whole depends merely upon the relative motions of the parts. We will further restrict ourselves by the condition that the link-work is such that its form is determinate when the relative position of two of its parts is assigned. Thus, a jointed parallelogram is completely determined in form if the angle between two of its sides is assigned. Instead of an angle, we may assign the length of a diagonal; then the fact that the sum of the squares of the diagonals is equal to that of the squares of the sides determines the other diagonal. This gives us the kinematics of the more complex arrangement called "lazy-tongs." The most important applications of this branch of our subject are to what is called "Mechanism." One important practical problem in that branch was suggested by a stationary steam-engine, in which it was required to connect, by link-work of some kind, a point (of the piston-rod), which had a to-and-fro motion in a straight line, with another point (of the beam) which had a to-and-fro motion in a circular arc. Watt's original solution of the problem depends ultimately upon the near approach to rectilinearity of the motion of any point of a rod whose extremities move in two circles in the same plane. Thus, if OP, PQ, QO′ (fig. 31) be three bars jointed together at P and Q, having O and O′ fixed, and

Lazy- tongs.

Watt's parallel motion.

the whole constrained to move in one plane, it is easy to see that the complete path of any point R of PQ is a species of figure of eight. A portion of that curve on each side of a point of inflexion (where the curvature vanishes) was found to be sufficiently straight for practical purposes.

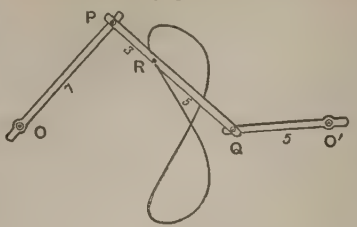

Fig. 31.

Peaucellier cell.

But the rigorous solution of this problem has only been arrived at in recent times; and the beautiful device of Peaucellier, which we will briefly explain, has led to a host of remarkable investigations and discoveries in a field regarded till lately as perfectly hopeless. A simple mode of arriving at Peaucellier's result is as follows.

Let PQ, PR (fig. 32) be *equal* links, and PO a link of a different length, all jointed together at P. Suppose O to be fixed, and Q and R constrained to move in a fixed straight line OQR, what is the relation between OQ and OR? We have, if PS be perpendicular to QR,

$$OP^2 = OS^2 + SP^2,$$
$$QP^2 = QS^2 + SP^2;$$

whence

$$OP^2 - QP^2 = OS^2 - QS^2 = OQ.OR.$$

Thus the rectangle under OQ and OR is constant; so that, if R were to describe a straight line, Q would describe a circle having O on its circumference. In practical application, to keep O, Q, R in one line, the parts of the link-work are doubled symmetrically about that line, so that it takes the form of a jointed rhombus PQP'R (fig. 33) with two equal links, PO, OP' attached at the extremities of a diagonal. As a very curious result of this arrangement, if OQ have its length changed by any very small amount, the corresponding change of length of OR is directly as $OR^2$ or inversely as $OQ^2$. Hence, as will be seen later, a constant force (towards or from O) acting at Q will be balanced by a force (from or towards O) acting at R and varying inversely as the square of OR.

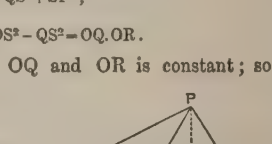

Fig. 32.

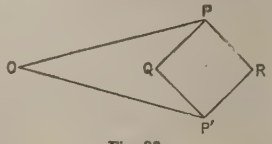

Fig. 33.

## DYNAMICS.

### *Definitions and General Considerations.*

Definition of physical particle.

§ 96. We commence with a few necessary definitions. A "physical particle" is a purely abstract conception, embodying together the ideas of inertia and of a geometrical point. It is, so to speak, a mathematical fiction, embracing only those properties which are required for our temporary purpose. Any mass, however large, can be treated as a particle, provided the forces to which it is subject are exerted in lines passing through its "centre of inertia" or "centre of mass" (this term will presently be defined), so as to be incapable of setting the mass into rotation. This is, to a first approximation, true of planetary motions, but when we look more closely into that question, so as for instance to take account of the oblate forms of the planets, we have to deal with forces which produce rotatory effects, such as "precession" and "nutation."

§ 97. The "quantity of matter" in a body, or the "mass," is proportional to the "volume" and the "density" conjointly. The "density" may therefore be defined as the quantity of matter in unit volume.

If M be the mass, $\rho$ the density, and V the volume of a homogeneous body, we have at once

$$M = V\rho,$$

provided we so take our units that unit of mass is the mass of unit volume of a body of unit density. Hence the dimensions of $\rho$ are $[ML^{-3}]$.

As will be presently explained, the most convenient unit mass is an *imperial pound*, or a *gramme*, of matter.

Momentum.

§ 98. The "quantity of motion," or the "momentum," of a moving body is proportional to its mass and velocity conjointly. As already stated this is, like velocity, a directed quantity, or "vector." Its dimensions are, of course, $[MLT^{-1}]$.

Change of momentum.

§ 99. "Change of quantity of motion," or "change of momentum," is proportional to the mass moving and the change of its velocity conjointly.

Change of velocity is to be understood in the general sense of § 32. Thus, with the notation of that section, if a velocity represented by OA be changed to another represented by OB, the change of velocity is represented in magnitude and direction by AB.

Rate of change of momentum.

§ 100. "Rate of change of momentum," or "acceleration of momentum," is proportional to the mass moving and the acceleration of its velocity conjointly. Thus (§ 36) the acceleration of momentum of a particle moving in a curve is $M\ddot{s}$ along the tangent, and $Mv^2/\rho$ in the radius of absolute curvature. The dimensions of this quantity are $[MLT^{-2}]$.

Kinetic energy.

§ 101. The "vis viva," or "kinetic energy," of a moving body is proportional to the mass and the square of the speed conjointly. If we adopt the same units of mass and velocity as above, there is particular advantage in defining kinetic energy as *half* the product of the mass into the square of its speed. Its dimensions are $[ML^2T^{-2}]$.

Rate of change of it.

§ 102. "Rate of change of kinetic energy," thus defined, is the product of the speed into the component of acceleration of momentum in the direction of motion.

For

$$\frac{d}{dt}\left(\frac{Mv^2}{2}\right) = Mv\dot{v} = v(M\ddot{s}).$$

The dimensions are $[ML^2T^{-3}]$.

Space-rate of change of it.

§ 103. The "space-rate of change of kinetic energy" is

$$\frac{d}{ds}\left(\frac{Mv^2}{2}\right) = Mv\frac{dv}{ds} = M\frac{dv}{dt} = M\ddot{s};$$

and its dimensions are $[MLT^{-2}]$, the same as those of "force" (§ 104).

Force.

§ 104. "Force," as we have already seen, is any cause which alters a body's natural state of rest, or of uniform motion in a straight line.

The three elements specifying a force, or the three elements which must be known before a clear notion of the force under consideration can be formed, are—its place of application, its direction, and its magnitude. The place of application may be a surface, as when one body presses on another; or it may be throughout the whole mass of a body, as in the case of the earth's attraction for it.

The "measure of a force" is the rate at which it produces momentum, or the momentum which it produces in unit of time, which is the same as what we have already called "rate of change of momentum." According to this method of measurement *the standard or unit force is that force which, acting on the unit of matter during the unit of*

*time, generates the unit of velocity.*" The dimensions of force are therefore $[MLT^{-2}]$.

§ 105. Hence the British absolute unit force is the force which, acting on one pound of matter for one second, generates a velocity of one foot per second.

[According to the system followed till lately in treatises on dynamics, the unit of mass is $g$ times the mass of the standard weight, $g$ being the numerical value of the acceleration produced (in some particular locality) by the earth's attraction. This definition, giving a varying unit of mass, is exceedingly inconvenient. In reality, standards of weight are *masses*, not *forces*. They are employed primarily for the purpose of measuring out a definite *quantity* of matter, not an amount of matter which shall be attracted by the earth with a given force.]

§ 106. To render our standard intelligible, all that has to be done is to find how many absolute units will produce, in any particular locality, the same effect as does gravity. The way to do this is to measure the effect of gravity in producing acceleration on a body unresisted in any way. The most accurate method is indirect, by means of the pendulum. The result of pendulum experiments made at Leith Fort, by Captain Kater, is that the velocity acquired by a body falling unresisted for one second is at that place 32·207 feet per second. The variation in gravity for one degree of difference of latitude about the latitude of Leith is only ·0000832 its own amount. The average value for the whole of Great Britain differs but little from 32·2; that is, the attraction of gravity on a pound of matter in the country is 32·2 times the force which, acting on a pound for a second, would generate a velocity of one foot per second. Thus, speaking very roughly, the British absolute unit of force is equal to the weight of about half an ounce. The quantity of 32·2 feet per second per second is usually called $g$. Its dimensions are obviously $[LT^{-2}]$. And, if M be the mass of a body, its weight is $Mg$. In the *Centimetre-Gramme-Second* system of units, the absolute unit of force produces in one second, in a mass of one gramme, a velocity of one centimetre per second.

§ 107. Forces (since they involve only direction and magnitude) may be represented, as velocities are, by vectors, that is, by straight lines drawn in their directions, and of lengths proportional to their magnitudes respectively.

Also the laws of composition and resolution of any number of forces acting at the same point are, as we shall presently show (§ 117), the same as those which we have already proved to hold for velocities; so that, with the substitution of force for velocity, § 30 is still true.

§ 108. The "component" of a force in any direction is therefore found by multiplying the magnitude of the force by the cosine of the angle between the directions of the force and the component. The remaining component in this case is perpendicular to the other.

It is very generally convenient to resolve forces into components parallel to three lines at right angles to each other, each such resolution being effected by multiplying by the cosine of the angle concerned.

The magnitude of the resultant of two or of three forces in directions at right angles to each other is the square root of the sum of their squares.

§ 109. The "centre of inertia or mass" of any system of material particles whatever (whether rigidly connected with one another, or connected in any way, or quite detached) is a point whose distance from any plane is equal to the sum of the products of each mass into its distance from the same plane, divided by the sum of the masses.

The distance from the plane $yz$ of the centre of inertia of masses $m_1$, $m_2$, &c., whose distances from the plane are $x_1$, $x_2$, &c., is therefore

$$\bar{x} = \frac{\Sigma(mx)}{\Sigma(m)};$$

and similarly for the other coordinates.

Hence its distance from the plane

$$\delta = \lambda x + \mu y + \nu z - a = 0$$

is

$$D = \lambda\bar{x} + \mu\bar{y} + \nu\bar{z} - a = \frac{\Sigma\{m(\lambda x + \mu y + \nu z - a)\}}{\Sigma(m)} = \frac{\Sigma(m\delta)}{\Sigma(m)},$$

as stated above. And its velocity perpendicular to that plane is

$$\frac{dD}{dt} = \frac{1}{\Sigma m}\Sigma\left\{ m\left(\lambda\frac{dx}{dt} + \mu\frac{dy}{dt} + \nu\frac{dz}{dt}\right)\right\} = \frac{\Sigma\left(m\frac{d\delta}{dt}\right)}{\Sigma m},$$

from which, by multiplying by $\Sigma m$, and noting that $\delta$ is the distance of $x$, $y$, $z$ from $\delta = 0$, we see that the sum of the momenta of the parts of the system in any direction is equal to the momentum in that direction of the whole mass collected at the centre of mass.

The problem of finding the centre of inertia of any given distribution of matter is a question of mere mathematics. We must confine ourselves to a few examples only. And, first, we may note that when a body is symmetrical about a plane the centre of inertia must obviously lie in that plane. Thus, as an ellipsoid and a rectangular parallelepiped have each three planes of symmetry, their centres of inertia lie at their centres of figure, where these planes meet. Again, it is obvious that, if a body can be divided into parts the centres of inertia of which lie on a straight line, the centre of inertia of the whole is in that line. Thus, as a triangular plate may be divided into strips parallel to one side, every one of which has its centre of inertia at its middle point, the centre of inertia of such a plate is the point of intersection of the bisectors of the sides. Its distance from any one side, treated as base, is therefore one-third of the height. Again, if a triangular pyramid (or tetrahedron) be divided into triangular slices by planes parallel to one face treated as base, the centres of inertia of all the slices lie in a straight line. Hence the distance of the centre of inertia from the base is one-fourth of the height. If the base be of any other form, it may be divided into triangles, and thus the whole pyramid (or cone) into tetrahedra, for each of which the same property holds. Hence the centre of inertia of a pyramid divides the line joining the vertex to the centre of inertia of the base in the ratio 3 : 1. All this is on the supposition that the solids treated of are of uniform density. When we deal either with more complex forms or with heterogeneous bodies, we must in general have recourse to integration.

For a continuous body we must take an element of mass, say $\rho\delta x\delta y\delta z$, at the point $x$, $y$, $z$ instead of the mass $m$ in our original formula. The sums then become integrals, and we have three expressions of the form

$$\bar{x} = \frac{\iiint \rho x\,dx\,dy\,dz}{\iiint \rho\,dx\,dy\,dz},$$

Here $\rho$ represents the density at $x$, $y$, $z$; and the integration extends through the whole volume of the body.

Thus, for a homogeneous *hemisphere* of radius $a$ we have, taking the base as the plane of $yz$,

$$\bar{x} = \frac{\int_0^a \pi(a^2 - x^2)x\,dx}{\frac{2}{3}\pi a^3} = \frac{3a}{8}.$$

The same value would be obtained for any semiellipsoid, whatever be the diametral section, provided $a$ be the height measured perpendicular to the base; and, in general, from the position of the centre of inertia of any body we may at once find that of the same body homogeneously strained.

Recurring to the hemisphere, suppose its density to be at every point proportional to the distance from the centre. Then we have, omitting common constant factors of numerator and denominator

$$\bar{x} = \frac{\int_0^a x\,dx \int_0^{\sqrt{a^2-x^2}} r\sqrt{x^2+r^2}\,dr}{\int_0^a dx \int_0^{\sqrt{a^2-x^2}} r\sqrt{x^2+r^2}\,dr} = \frac{2a}{5}.$$

A uniform hemispherical shell gives

$$\bar{x} = \tfrac{1}{2}x$$

by the well-known result due to Archimedes. From this, by taking concentric hemispherical elements, we may reproduce the preceding result for a solid hemisphere in the form

$$\bar{x} = \frac{\int_0^a 2\pi x^2 dx \,.\, x \,.\, \frac{1}{2}x}{\int_0^a 2\pi x^2 dx \,.\, x} = \frac{2a}{5}.$$

Here the first factor under each integral sign is the volume of the hemispherical element of radius $x$, and the second is proportional to its density.

If the density of a thin uniform spherical shell be everywhere proportional to the inverse cube of the distance from an internal point, that point is the centre of inertia. For, if a double cone of small angle be drawn, having that point as vertex, the volumes of the portions of the shell which it cuts out are as the squares of their distances from the vertex. Hence their masses are inversely as their distances from the vertex, which is thus their centre of inertia. The whole shell may be divided into pairs of elements for each of which this is true.

The reader may easily prove that, if the density of a solid sphere be inversely as the fifth power of the distance from an external point, the "electric image" of that point is the centre of inertia.

It may be proved in the last two examples that this point is not merely the centre of inertia of such distributions of matter, but that it is also a true "centre of gravity" in the sense that the whole attracts, and is attracted by, any other body whatever, as if its whole mass were concentrated in this point.

Moment of momentum.

§ 110. By introducing in the definition of moment of velocity (§ 46) the mass of the moving particle as a factor, we have an important element of dynamical science, the "moment of momentum." The laws of composition and resolution are the same as those already explained. Its dimensions are $[ML^2T^{-1}]$.

§ 111. A force is said to "do work" if it moves the body to which it is applied; and the work done is measured by the resistance overcome, and the space through which it is overcome, conjointly. The dimensions of work are therefore $[MLT^{-2}.L]$ or $[ML^2T^{-2}]$, the same as those of kinetic energy.

Thus, in lifting coals from a pit, the amount of work done is proportional to the weight of the coals lifted; that is, to the force overcome in raising them; and also to the height through which they are raised. The unit for the measurement of work, adopted in practice by British engineers, is that required to overcome the weight of a pound through the height of a foot, and is called a "foot-pound."

In purely scientific measurements, the unit of work is not the foot-pound, but the absolute unit force (§ 105) acting through unit of length.

If the weight be raised obliquely, as, for instance, along a smooth inclined plane, the distance through which the force has to be overcome is increased in the ratio of the length to the height of the plane; but the force to be overcome is not the whole weight, but only the resolved part of the weight parallel to the plane; and this is less than the weight in the ratio of the height of the plane to its length. By multiplying these two expressions together, we find, as we might expect, that the amount of work required is unchanged by the substitution of the oblique for the vertical path.

Generally, if $s$ be an arc of the path of a particle, S the tangential component of the applied forces, the work done on the particle between any two points of its path is

$$\int S ds,$$

taken between limits corresponding to the initial and final positions.

Referred to rectangular coordinates, it is easy to see, by the law of resolution of forces, § 117, that this becomes

$$\int \left( X\frac{dx}{ds} + Y\frac{dy}{ds} + Z\frac{dz}{ds} \right) ds,$$

where X is the component force parallel to the axis of $x$.

§ 112. Thus it appears that, for any force, the work done during an indefinitely small displacement of the point of application is the product of the resolved part of the force in the direction of the displacement into the displacement.

From this it follows that, if the motion of a body be always perpendicular to the direction in which a force acts on it, the force does no work. Thus the mutual normal pressure between a fixed and a moving body, the tension of the cord to which a pendulum bob is attached, the attraction of the sun on a planet if the planet describe a circle with the sun in the centre, are all cases in which no work is done by the force.

In fact the geometrical condition that the resultant of X, Y, Z shall be perpendicular to $ds$ is

$$X\frac{dx}{ds} + Y\frac{dy}{ds} + Z\frac{dz}{ds} = 0,$$

and this makes the above expression for the work vanish.

Transformation of work.

§ 113. Work done on a body by a force is always shown by a corresponding increase of kinetic energy, if no other forces act on the body which can do work or have work done against them. If work be done against any forces, the increase of kinetic energy is less than in the former case by the amount of work so done. In virtue of this, however, the body possesses an equivalent in the form of "potential energy," if its physical conditions are such that these forces will act equally, and in the same directions, when the motion of the system is reversed. Thus there may be no change of kinetic energy produced, and the work done may be wholly stored up as potential energy.

Potential energy.

Thus a weight requires work to raise it to a height, a spring requires work to bend it, air requires work to compress it, &c.; but a raised weight, a bent spring, compressed air, &c., are *stores* of energy which can be made use of at pleasure.

Example of work.

As an illustration of the calculation of work, take the following question.

Suppose one end of an elastic string to be attached to a mass resting on the ground, what amount of work must be done, in raising the other end vertically, before the mass is lifted?

If $x$ be at any instant the length of the string, $l$ its original length, its tension is

$$E\frac{x-l}{l}.$$

Hence the value of $x$, when the mass is just lifted, is

$$x_1 = l\left(1 + \frac{W}{E}\right),$$

where W is the weight of the mass.

The whole work done is the sum of all the elementary instalments of the form

$$E\frac{x-l}{l}dx \,.$$

These must be summed up from $x = l$ to $x = x_1$, so that the result required is

$$\tfrac{1}{2}l\frac{W^2}{E}.$$

It is to be observed that this quantity becomes less in proportion as E is greater, *i.e.*, the less extensible is the string.

An interesting variation of the question consists in supposing the upper end of the string to be attached to the rim of a wheel, rough enough to prevent slipping. Here the various portions of the string are wound on in a more and more stretched state as the operation proceeds.

At any stage of the operation let $x$ be the unstretched length of the part already wound on the wheel. The tension of the free part is then

$$E\frac{l-(l-x)}{l-x}.$$

During the next elementary step of the process a portion $dx$ is wound on. But its stretched length is

$$\frac{l}{l-x}dx.$$

Hence the element of work is

$$\mathrm{E}l\,\frac{l-(l-x)}{(l-x)^2}dx,$$

This must be integrated between the limits 0 and W of

$$\mathrm{E}\,\frac{l-(l-x)}{l-x}\ ;$$

or from $l-x=l$ to $l-x=\frac{\mathrm{E}l}{\mathrm{E}+\mathrm{W}}$ ; and the result is

$$l\left(\mathrm{W}+\mathrm{E}\log\frac{\mathrm{E}}{\mathrm{E}+\mathrm{W}}\right);$$

which, when E is very great compared with W, gives the previous result.

*Further Comments on the First Two Laws of Motion.*

§ 114. We are now prepared to consider, more closely than we could at starting, the bearing of the various clauses of each of Newton's Laws. Thus, from the first law we may draw the following immediate consequences.

The times during which any particular body, not compelled by force to alter the speed of its motion, passes through equal distances are equal. And, again, every other body in the universe, not compelled by force to alter the speed of its motion, moves over equal distances in successive intervals, during which the particular chosen body moves over equal distances. The earth, in its rotation about its axis, presents us with a case of motion in which the condition of not being compelled by force to alter its speed is more nearly fulfilled than in any other which we can easily or accurately observe. Hence the numerical measurement of time practically rests on defining "equal intervals of time" as *times during which the earth turns through equal angles.*

§ 115. It has been objected to this statement that we begin by defining uniform motion by the description of equal spaces in equal times, and then employ this definition as a mode of measuring equal times. The objection, however, is not valid; for, if we agree to measure equal intervals by the undisturbed motion of any one physical mass, we find that in the successive intervals so determined all other absolutely free physical masses describe successive equal spaces.

Measure of force.

§ 116. Again, from the second law we see that, if we multiply the change of velocity, geometrically determined, by the mass of the body, we have the change of motion (§ 99) referred to in the law as the measure of the force which produces it. In the statement of the second law there is nothing said about the actual motion of the body before it was acted on by the force; the same force will produce precisely the same change of motion in a body whether the body be at rest or in motion with any velocity whatever. Again, nothing is said as to the body being under the action of one force only; so that we may logically put part of the second law in the following (apparently) amplified form:—

*When any forces whatever act on a body, then, whether the body be originally at rest or moving with any velocity and in any direction, each force produces in the body the exact change of motion which it would have produced if it had acted singly on the body originally at rest.*

Composition of forces.

§ 117. Since now forces are measured by the changes of motion they produce, and their directions assigned by the directions in which these changes are produced, and since the changes of motion of one and the same body are in the directions of and proportional to the changes of velocity, a single force, measured by the resultant change of velocity, and in its direction, will be the equivalent of any number of simultaneously acting forces. Hence

*The resultant of any number of forces (applied at one point) is to be found by the same geometrical process as the resultant of any number of simultaneous velocities.*

From this follows at once (§ 30) the construction of the "parallelogram of forces" for finding the resultant of two forces acting at the same point, and the "polygon of forces" for the resultant of any number of forces acting at a point. And, so far as a single particle is concerned, we have at once the whole subject of Statics.

Measure of mass, and of force.

§ 118. The second law gives us the means of measuring force, and also of measuring the mass of a body.

For, if we consider the actions of various forces upon the same body for equal times, we evidently have changes of velocity produced which are proportional to the forces. The changes of velocity, then, give us in this case the means of comparing the magnitudes of different forces Thus the speeds acquired in one second by the same mass (falling freely) at different parts of the earth's surface give us the relative amounts of the earth's attraction at these places.

Again, if equal forces be exerted on different bodies, the changes of velocity produced in equal times must be *inversely* as the masses of the various bodies. This is approximately the case, for instance, with trains of various lengths drawn by the same locomotive.

Gravity.

Again, if we find a case in which different bodies, each acted on by a force, acquire in the same time the same changes of velocity, the forces must be proportional to the masses of the bodies. This, when the resistance of the air is removed, is the case of falling bodies; and from it we conclude that the *weight of a body in any given locality, or the force with which the earth attracts it, is proportional to its mass.* This is no mere truism, but an important part of the grand *Law of Gravitation.* Gravity is not, like magnetism for instance, a force depending on the quality as well as on the quantity of matter in a particle.

Translation from kinematics into kinetics.

§ 119. It appears, lastly, from this law that every theorem of kinematics connected with acceleration has its counterpart in kinetics. Thus, for instance (§ 36), we see that the force under which a particle describes any curve may be resolved into two components, one in the tangent to the curve, the other *towards* the centre of curvature,—their magnitudes being the rate of change of momentum in the direction of motion, and the product of the momentum into the angular velocity about the centre of curvature, respectively. In the case of uniform motion, the first of these vanishes, or the whole force is perpendicular to the direction of motion. When there is no force perpendicular to the direction of motion, there is no curvature, or the path is a straight line.

Hence, if we resolve the forces acting on a particle of mass $m$, whose coordinates are $x$, $y$, $z$, into three rectangular components X, Y, Z, we have the equations originally given by Maclaurin, viz.,

$$m\frac{d^2x}{dt^2}=\mathrm{X},\quad m\frac{d^2y}{dt^2}=\mathrm{Y},\quad m\frac{d^2z}{dt^2}=\mathrm{Z}.$$

In several of the examples which follow, these equations will be somewhat simplified by assuming unity as the mass of the moving particle. When this cannot be done, it is sometimes convenient to assume X, Y, Z as the component forces on *unit* mass, and the previous equations become

$$m\frac{d^2x}{dt^2}=m\mathrm{X},\ \&c.,$$

from which $m$ may of course be omitted.

[Some confusion is often introduced by the division of forces into "accelerating" and "moving" forces; and it is even stated occasionally that the former are of *one*, and the latter of *four* linear dimensions. The fact is, however, that an equation such as

$$\frac{d^2x}{dt^2}=\mathrm{X}$$

may be interpreted either as dynamical or as merely kinematical. If kinematical, the meanings of the terms are obvious; if dynamical, the unit of mass must be understood as a factor on the left-hand side, and in that case X is the $x$-component, per unit of mass, of the whole force exerted on the moving body.]

If there be no acceleration, we have of course equilibrium among

the forces. Hence the equations of motion of a particle are changed into those of equilibrium by putting

$$\frac{d^2x}{dt^2} = 0, \text{ \&c.}$$

Statical friction.

§ 120. We have now all that is necessary for the dynamics of a single particle, with exception of the experimental laws of friction. These, very nearly as they were established by Coulomb, we will now give.

To produce sliding of one flat-faced solid on another requires a tangential force which is directly proportional to the normal pressure between the surfaces, and whose actual magnitude is found from this pressure by means of a factor called the "coefficient of statical friction." This coefficient depends upon the nature of the solids, the roughness or smoothness of the surfaces in contact, and the amount of tallow, oil, &c., with which they have been smeared. It also depends upon the time during which they have been left in contact. It is only in extreme cases dependent on the area of the surfaces in contact.

§ 121. When the forces applied are insufficient to produce sliding, the whole amount of friction is not called into play; it is called out to an amount just sufficient to balance the other forces. Thus there are two quite distinct problems connected with the statics of friction:—the first, to determine the amount of friction called into play under given circumstances; the second, to find the limiting circumstances under which, with friction, equilibrium is possible. When motion is produced, there is still friction (now called "kinetic"). It follows the same laws as does statical friction, only that the coefficient, which is approximately independent of the velocity, is usually considerably less than the statical coefficient.

Kinetic friction.

*Statics of a Particle.*

Equilibrium of a particle.

§ 122. By § 117, forces acting at the same point, or on the same material particle, are to be compounded by the same laws as velocities. Therefore the sum of their resolved parts in any direction must vanish if there is equilibrium; whence the necessary and sufficient conditions are found by resolving in three directions at right angles to one another.

They follow also directly from Newton's statement with regard to work, if we suppose the particle to have any velocity, constant in direction and magnitude (and by § 6 this is the only general supposition we can make, since absolute rest has for us no meaning). For the work done in any time is the product of the displacement during that time into the algebraic sum of the effective components of the applied forces, and there is no change of kinetic energy. Hence this sum must vanish for *every* direction. Practically, as any displacement may be resolved into three, in any three directions not coplanar, the vanishing of the work for any one such set of three suffices for the criterion. But, in general, it is convenient to assume them in directions at right angles to each other.

Hence, for the equilibrium of a material particle, it is *necessary*, and *sufficient*, that the (algebraic) sums of the applied forces, resolved in any one set of three rectangular directions, should vanish.

This statement gives at once the result that, if $X_1$, $Y_1$, $Z_1$, $X_2$, $Y_2$, $Z_2$, &c., be the components (parallel to the three axes) of the forces $P_1$, $P_2$, &c., acting on the particle, we must have

$$\Sigma(X) = 0, \quad \Sigma(Y) = 0, \quad \Sigma(Z) = 0.$$

When these conditions are not satisfied, there is a resultant force P, with direction cosines $\lambda$, $\mu$, $\nu$, such that

$$P\lambda = \Sigma(X), \quad P\mu = \Sigma(Y), \quad P\nu = \Sigma(Z)$$

Attraction.

§ 123. By far the most extensive series of examples of the composition of forces acting on a single particle is furnished by the theory of "attraction," where each particle of the attracting mass exerts upon the attracted particle a force in the direction of the line joining them, and of magnitude depending on their masses and their mutual distance only. See POTENTIAL.

Examples of particle equilibrium

§ 124. When there are but three forces acting on the particle, their directions to give equilibrium must obviously be in one plane. For, if the third were not in the plane of the other two, it would have an uncompensated component perpendicular to that plane. Hence this case is always at once reducible to the triangle or the parallelogram of forces; and the magnitudes of each of the three forces are respectively proportional to the sines of the angles between the directions of the other two.

Thus, when a pellet is supported by two strings, as in fig. 34, we may proceed as follows to determine their tensions. Let P be the pellet, of weight W, and let AP, BP be the strings attached to points A and B respectively. Let their tensions be T and T'. The remark above shows that the strings must hang in a vertical plane, since the force W acts in a vertical line. Since A, B, and the length of the strings are given, the figure is perfectly definite. Draw $P\gamma$ vertically upwards, and make its length represent, on any assumed scale, the value of W. Draw $\gamma\beta$ parallel to AP, and let it meet BP in $\beta$. Then $\beta\gamma$ represents T, and $P\beta$ represents T', in direction and also in magnitude, on the same scale in which $\gamma P$ represents W. This case leads to nothing but the determination of the tensions, since the form of the figure is definite.

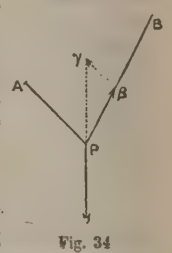

Fig. 34

Next, let one of the tensions be given in magnitude. To effect this, we may suppose the end of PB not to be fastened at B, but to pass over a smooth pulley and support a weight Q. Let fig. 35 represent the state of equilibrium, and let the same construction as before be made. Then we must have $\gamma P : P\beta :: W : Q$; or, writing it in terms of angles,

$$\sin APB : \sin AP\gamma :: W : Q.$$

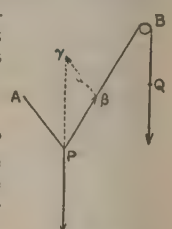

Fig. 35.

A and B and the direction of $\gamma P$ being given, this datum suffices for the drawing of the figure; *i.e.*, for the calculation of the angles. A little consideration will show that, however small Q be, provided the string supporting it be long enough, there is always *one definite* position of equilibrium. The actual calculations in such a case as this are troublesome. It was chosen mainly on that account, so as to show, in a simple case, how pure geometrical processes may occasionally save the necessity of a tedious trigonometrical investigation. But a still simpler method will be afterwards explained, viz., that, for a position of stable equilibrium, the potential energy must be a *minimum*. Now, to apply this to our example, we see that any downward displacement of Q produces an upward motion of P. But when AP is nearly vertical the vertical displacement of P is indefinitely smaller than that of Q, so that Q must go down. On the other hand if APB be nearly a straight line, a displacement of P produces an indefinitely smaller displacement of Q. Hence P must go down. And these results are in character independent of the relative magnitudes of P and Q, provided both be finite.

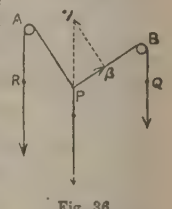

Fig. 36.

Finally, let both tensions be constant. Here we must imagine pulleys both at A and at B (fig. 36), with weights

R and Q attached to the ends of the strings. But now we see that we must have the limiting condition

$$R+Q>W.$$

This is merely the geometrical condition that

$$P\beta+\beta\gamma>P\gamma$$

Here the magnitudes of all three sides of $P\beta\gamma$ are given. Hence its angles are given, and the sole position of equilibrium is at once found.[1]

Particle on fixed surface.

§ 125. Now take the case of a particle resting on a surface. As we are concerned only with the portion of the surface immediately contiguous to the position of the particle, we may substitute for it its tangent plane at that point (except, of course, at singular points, where there may be an infinite number of tangent planes; but such cases we do not consider). Hence the problem reduces itself in all cases to that of a particle resting on an inclined plane.

If the plane be smooth, the particle cannot remain in equilibrium unless some force is present to prevent its sliding down. Let us suppose it to be supported by a force, F, acting upwards along the plane (fig. 37). Then we have three forces at work:—the weight P acting vertically downwards; the supporting pressure of the plane R, which necessarily acts perpendicularly to the surface; and the third force, just mentioned, which we see by previous considerations must be in the plane of the other two, and must therefore lie along the line of greatest slope of the plane. We might construct a triangle of forces as in the previous examples, but we will now vary the process, and resolve the forces in two directions at right angles to one another in their common (vertical) plane.

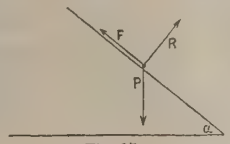

Fig. 37

Let $\alpha$ be the angle of inclination of the plane to the horizon, then the algebraic sum of the components of the forces must vanish both horizontally and vertically This gives us the two conditions

$$F\cos\alpha-R\sin\alpha=0,\quad F\sin\alpha+R\cos\alpha-P=0$$

From these we obtain at once

$$F=P\sin\alpha,\quad R=P\cos\alpha$$

Now the choice of mutually perpendicular directions in which to resolve was at our option, and we see that had we chosen to resolve *along* and *perpendicular to* the plane we should have obtained the last two equations, which are equivalent to, but simpler than, the former ones, which were obtained by resolving horizontally and vertically. Theoretically speaking, it does not matter which system we choose; in practice, however, it is well to select the directions which will give the required results in the simplest form. The full value of a proper selection will not be felt till we come to the statics of a rigid solid.

Friction.

If we suppose the plane to be rough, friction alone may suffice to develop the requisite force F. But the utmost value of the friction is (§ 120) $\mu R$. Hence the particle will be on the point of sliding if

$$\mu R=F=P\sin\alpha,$$

Divide the members of this equation by those of

$$R=P\cos\alpha,$$

and we find

$$\mu=\tan\alpha$$

Hence, so long as the coefficient of friction is greater than the tangent of the inclination of the plane to the horizon, the friction will suffice to prevent sliding. More and more is called into play as the inclination of the plane increases, and finally when

Angle of repose.

$$\tan\alpha=\mu$$

the particle is just about to slide down. This simple idea, taken along with Coulomb's results (§ 120), points to a very easy method of determining the coefficient of friction between any two substances. The limiting angle defined by

$$\alpha=\tan^{-1}\mu$$

is called, on account of this property, the "angle of repose."

Support by elastic string.

§ 126. Let us now suppose the particle to be, in part, supported by an elastic string fixed at a point in the plane, and lying in the line of greatest slope. (This modification is introduced to show the nature of cases in which there are *limits* between which equilibrium is possible.) We assume "Hooke's Law," viz., that the tension of an elastic string, drawn out from its natural length $l$ to length $l'$, is expressed by

$$E\frac{l'-l}{l},$$

where E is a definite constant, representing theoretically the tension which would just double the length of the string.

Our equations are exactly the same as before, only that F consists now of two parts,—one due to friction, the other to the elasticity of the string. Thus

$$F=F_1+E\frac{l'-l}{l}=P\sin\alpha,\qquad R=P\cos\alpha.$$

Now, when sliding is about to commence downwards we have

$$F_1=\mu R.$$

If the particle is about to be dragged upwards,

$$F_1=-\mu R.$$

Hence for the two extreme positions of equilibrium

$$\pm\mu P\cos\alpha+E\frac{l'-l}{l}=P\sin\alpha.$$

Hence the limiting positions of equilibrium of the particle are given by its distance from the fixed end of the string—

$$l'=l+\frac{Pl}{E}(\sin\alpha\mp\mu\cos\alpha).$$

If $l'$ be less than the smaller of these, gravity pulls the particle down; if it be greater than the larger of them, the tension of the string pulls the particle up. In intermediate positions the full available friction is not called into play.

Equilibrium with a system of equal forces tending to given points.

§ 127 Next, let a small ring P (fig. 38) be attached to one end of a string. Let the string pass round two smooth pulleys B, C, at different points, then be passed through the ring, then round two more pulleys D, E, and through the ring again, and so on,—the other end being either fastened to the ring or attached to a fixed point. It is required to find the position of equilibrium of the ring when the string is drawn tight, by operating on the lap of it behind two of the pulleys.

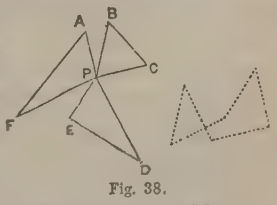

Fig. 38.

This is equivalent, from the physical point of view, to finding the position of equilibrium of a particle acted on by a number of *equal* forces each directed towards a given point. From the geometrical point of view its solution obviously answers the question, "Find the point the sum of whose distances from a number of given points is the least possible." The points need not lie all in one plane. The solution is, from the polygon of forces, that in

[1] We have assumed here, what is properly part of the results of the *third* law of motion, that the tension of a weightless string, passing over a smooth pulley, is in the direction of its length, and of the same amount at all points.

the equilibrium position the laps of the string, from the ring outwards, are parallel to the respective sides of a closed equilateral polygon, taken all in the same direction. That the solution is unique will be seen at once by considering a displacement of the ring, for the resultant of the forces obviously tends to diminish the displacement. When there are but three forces, their directions must be inclined at angles of 120° to one another (fig. 39). Thus we have immediately the solution of the celebrated geometrical problem, "Find the point the sum of whose distances from three given points is the least possible."

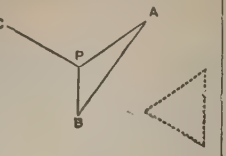

Fig. 39.

§ 128. If, in the first problem of § 124 above, the particle were supported by three strings, instead of two, each attached to a fixed point, we should first have to assure ourselves that all three are brought into play. For, if not, the problem is reduced to the former case. The obvious condition is that, when the three strings are simultaneously tight, and the points of suspension are not in one vertical plane, the particle supported shall be situated *within* the triangular prism formed by vertical planes passing through each pair of points. If this condition be satisfied, the process for determining the tensions of the strings is merely to construct a parallelepiped, three of whose edges lie along the strings, while the conterminous diagonal is vertical. This leads to an obvious geometrical construction; and, when it is carried out, the lengths of the various edges are to the diagonal as the corresponding tensions to the weight of the particle. When the three points are in one vertical plane, nothing short of infinitely perfect fitting will, in general, bring all three strings simultaneously tight; and in this case the problem, mathematically considered, is indeterminate.[1] When the strings are sufficiently extensible, all will be brought into play; and, with sufficient data, the problem is determinate.

### *Kinetics of a Particle with One Degree of Freedom.*

§ 129. Here the motion is rectilinear, or at least takes place in some assigned curve.

The simplest case is that of a falling stone, when the effect of the resistance of the air is set aside and the acceleration due to gravity is reckoned the same at all elevations. This has already been treated with sufficient detail as a matter of pure kinematics, §§ 28, 29.

Sliding on inclined plane.

§ 130. When the particle, instead of falling freely, is constrained by a smooth inclined plane on which it slides, we see that (so long as it moves on the line of greatest slope) its weight $Mg$ has components, $Mg\sin\alpha$ tangential to the plane and $Mg\cos\alpha$ perpendicular to it, $\alpha$ being the inclination of the plane to the horizon. The latter component produces the normal pressure on the plane, and is the only contributor to it, since there is no curvature. The former produces the acceleration of the motion. Thus the acceleration is now $g\sin\alpha$ only; but, with this change, the results of § 29 still hold.

Plane rough.

§ 131. If the plane be rough, with coefficient of statical friction $\mu$, it can furnish (§ 120) a force of friction tending to prevent motion, of any amount up to

$$\mu Mg\cos\alpha .$$

If this be less than $Mg\sin\alpha$, motion will commence, and the force accelerating it will be

$$Mg\sin\alpha - \mu' Mg\cos\alpha ,$$

where $\mu'$ is the coefficient of kinetic friction (§ 121). Thus the same results as in § 29 still hold, but with $g(\sin\alpha - \mu\cos\alpha)$ instead of $g$. As we have seen that $\mu' < \mu$, *accelerated* motion can take place down an inclined plane in certain cases where the mass, if once at rest, would not start.

Body falling to earth from a great distance.

§ 132. As a slightly more complex case, let us now take again the problem of free motion in a vertical line, but allow for the diminution of gravity as the distance from the earth increases.

The weight of a particle of mass $m$ at the earth's surface is $mg$. At a distance $x$ from the centre, it is, therefore,

$$m g \frac{R^2}{x^2} ,$$

where R is the radius of the earth, supposed spherical. This acts downwards, or in the direction opposite to that in which $x$ increases. Hence, equating it, with its proper sign, to the rate of acceleration of momentum, we have for the equation of motion

$$m\ddot{x} = -mg\frac{R^2}{x^2} .$$

Here the right hand member is a function of $x$ only.

Multiply by $\dot{x}dt$, and integrate, and we have, leaving out the extraneous factor $m$ (the possibility of doing this showing that the motion is the same for all masses),

$$\tfrac{1}{2}\dot{x}^2 + C = \frac{R^2 g}{x} .$$

If V be the speed at the earth's surface (where $x = R$),

$$\tfrac{1}{2}V^2 + C = Rg .$$

Also if the particle turns, to come down again, at the height $h$ above the surface,

$$C = \frac{R^2 g}{R+h} .$$

Hence

$$\tfrac{1}{2}V^2 = Rg\left(1 - \frac{R}{R+h}\right) = gh\frac{R}{R+h} .$$

This shows the amount of error in the approximate formula (§ 28) for projectiles,—

$$\tfrac{1}{2}V^2 = gh .$$

Meteorite

If the particle be supposed to have been originally at rest, at a practically infinite distance from the earth (a case which may occur with a meteorite for instance), we have $\dot{x} = 0$ when $x = \infty$, and our formula becomes

$$\tfrac{1}{2}\dot{x}^2 = \frac{R^2 g}{x} .$$

The speed with which the mass reaches the surface (where $x = R$) is therefore $\sqrt{2gR}$, *i.e.*, that which it would acquire by falling, under constant acceleration $g$, through a height equal to the earth's radius.

In this special case, the second integral is

$$\tfrac{2}{3}x^{\frac{3}{2}} = \sqrt{2g}Rt + C' .$$

The second integral, in its general form, is a little complex; but we may avoid it by means of a geometrical construction, founded on the results of the investigation of planetary motion soon to be given.

Hailstone or raindrop.

§ 133. Let us next take a case in which the acceleration depends upon the speed of the moving body. A sufficiently simple one is furnished by a falling raindrop, or hailstone, when the resistance of the air is taken into account. For the moderate speeds with which such bodies move, the resistance varies, at least approximately, as the square of the speed. To avoid needless complexity, we neglect here the variation of gravity due to changes of vertical height.

Suppose the particle to have been projected vertically upwards from the origin with the speed V, and let $v$ be its speed at any time $t$, and $x$ its distance from the origin at that time.

If we assume $k$ to be the speed with which the particle must move so that the retardation due to the resistance may be equal to $g$, the retardation when the speed is $v$ will be represented by $g\frac{v^2}{k^2}$.

Let the axis of $x$ be drawn vertically upwards; then the resistance acts *with* gravity, and the equation of motion upwards is

$$\frac{dv}{dt} = -\frac{g}{k^2}(k^2 + v^2),$$

or

$$v\frac{dv}{dx} = -\frac{g}{k^2}(k^2 + v^2).$$

[1] Of course, physically, there is no indeterminateness, even with perfectly inextensible strings.

Integrating, and determining the constants so that, when $x=0$, $t=0$ and $v=V$, we obtain

$$\frac{gt}{k} = \tan^{-1}\frac{V}{k} - \tan^{-1}\frac{v}{k} = \tan^{-1}\frac{k(V-v)}{k^2+Vv},$$

$$\frac{2gx}{k^2} = \log\frac{k^2+V^2}{k^2+v^2}.$$

Let T be the time at which the speed becomes zero, and $h$ the corresponding value of $x$, then

$$T=\frac{k}{g}\tan^{-1}\frac{V}{k}, \text{ and } h=\frac{k^2}{2g}\log\left(1+\frac{V^2}{k^2}\right).$$

After this the particle begins to return; the resistance therefore acts *against* gravity, and the equation of motion is

$$\frac{dv}{dt} = -\frac{g}{k^2}(k^2-v^2),$$

or

$$v\frac{dv}{dx} = -\frac{g}{k^2}(k^2-v^2).$$

Integrating, and determining the constants so that, when $v=0$, $x=h$ and $t=T$, we obtain

$$\frac{2g}{k}(t-T) = \log\frac{k-v}{k+v},$$

$$\frac{2g}{k^2}(h-x) = \log\frac{k^2}{k^2-v^2}.$$

(It must be remembered that $v$ is now negative.)

Let U be the speed with which the particle returns to the point of projection; then, putting $x=0$ in the latter equation, we obtain

$$\frac{U^2}{k^2} = 1-\epsilon^{-\frac{2gh}{k^2}};$$

or, substituting for $h$ its value,

$$\frac{U^2}{k^2} = \frac{V^2/k^2}{1+V^2/k^2},$$

whence

$$\frac{1}{U^2}-\frac{1}{V^2}=\frac{1}{k^2}.$$

It is to be observed that $k$ is the "terminal velocity," as it is called, *i.e.*, the speed to which that of a falling body continually tends, whether its original speed have been greater or less than this limit.

It is to be observed also that (strictly) we should write $g(1-\alpha)$ for $g$, where $\alpha$ is the specific gravity of air, to take account of the apparent loss of weight of a raindrop on account of immersion in air.

When $k$ is very large, *i.e.*, the absolute amount of resistance very small, as in the case of air, the general integrals in the second case above become, by expanding the logarithms,

$$-\frac{2g}{k}(t-T) = \frac{2v}{k}+\frac{2v^3}{3k^3}+\ \dots$$

$$\frac{2g}{k^2}(h-x) = \frac{v^2}{k^2}+\frac{v^4}{2k^4}+\ \dots$$

of which the terms independent of $k$ are

$$v=-g(t-T),$$
$$v^2=2g(h-x).$$

These, if we remember that $t-T$ is the time of fall, and $h-x$ the space fallen through, are at once recognized as the ordinary formulæ of § 28. The modification due to the resistance is shown approximately by the second terms on the right-hand side of the developments above.

The necessity for this double investigation, one part for the ascent, the other for the descent, is due to the non-conservative, or "dissipative," character of the force of resistance.

Simple pendulum.

§ 134. As an illustration of constraint by a smooth curve, let us take the case of a simple pendulum. Let O (fig. 40) be the point of suspension, P the position of the bob at any time $t$. Then, if PG represent the weight of the bob, and be resolved into PH, HG respectively along, and perpendicular to, the tangent at P, we see that PH produces the acceleration of the motion, while the tension of the cord balances HG and also furnishes the acceleration perpendicular to the direction of motion which is required to produce the curvature of the path. PH is (*cæteris paribus*) proportional to the sine of PGH, that is, of POA. Hence the acceleration is proportional to the sine of the angular displacement. When that angle is small it may be used in place of its sine. Hence, for small vibrations, the acceleration is proportional to the displacement, and the motion is "simple harmonic." The time of vibration, being (§ 51) $2\pi\sqrt{\text{displacement}/\text{acceleration}}$, is here

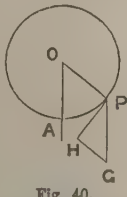

Fig. 40.

$$2\pi\sqrt{\frac{l\theta}{g\sin\theta}} = 2\pi\sqrt{\frac{l}{g}}, \text{ approximately.}$$

The rigorous solution of the pendulum problem requires the use of elliptic functions.

§ 135. Some very curious properties of pendulum motion are easily proved by geometrical processes. The whole theory of the motion in a vertical plane of a particle attached by a weightless rod to a fixed point, whether it oscillate as a pendulum or perform continuous rotations, may be deduced from the two following propositions, which are easily established by geometrical processes in which corresponding in definitely small motions are compared.

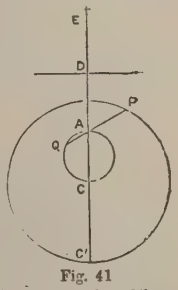

Fig. 41

(1) To compare different cases of continuous rotation. Let DA (fig. 41) be taken equal to the tangent from D to the circle BPC', whose centre C is vertically under D. Let PAQ be any line through A, cutting in Q the semicircle on AC. Also make DE = DA. Then, if P move under gravity with speed due to the level of D, Q moves with speed due to the level of E, the acceleration due to gravity being reduced in the ratio $AC^2 : 2BC^2$.

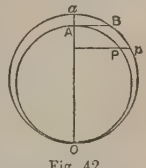

Fig. 42.

(2) To compare continuous rotation with oscillation. Let two circles touch one another at their lowest points O (fig. 42); compare the arcual motions of points P and $p$, which are always in the same horizontal line. Draw the horizontal tangent AB. Then, if P move, with speed due to $g$ and level $a$, continuously in its circle, $p$ oscillates with speed due to level AB and acceleration

$$g\frac{aO^2}{AO^2}.$$

§ 136. Two particles are projected from the same point, in the same direction, and with the same speed, but at different instants, in a smooth circular tube of small bore whose plane is vertical, to show that the line joining them constantly touches another circle. Motion in vertical circle.

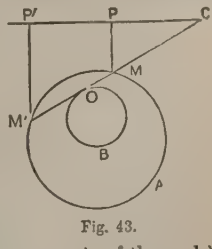

Fig. 43.

Let the tube be called the circle A, and the horizontal line, to the level of which the speed is due, L. Let M, M' (fig. 43) be simultaneous positions of the particles. Suppose that MM' passes into its next position by turning about O, these two lines will intercept two indefinitely small arcs at M and M' which (by a property of the circle) are in the ratio MO : OM'. Let another circle B be described touching MM' in O, and such that L is the radical axis of A and B. Let MP, M'P' be drawn perpendicular to L. Let M'M cut L in C. Then, by the property of the radical axis, $CO^2 = CM.CM'$; from which we have, by geometry,

$$CM : CM' = OM^2 : OM'^2$$

or $$OM^2 : OM'^2 = PM : P'M',$$

But $$(\text{speed at M})^2 : (\text{speed at M'})^2 = PM : P'M'.$$

Hence the speeds of M and M′ are as MO : OM′, and therefore, by what we have stated above about elementary arcs at M and M′, the proximate position of MM′ is also a tangent to B, which proves the proposition.

Geometrical theorem.

It is easily seen from this that, if one polygon of a given number of sides can be inscribed in one circle and circumscribed about another, an infinite number can be drawn. For this we have only to suppose a number of particles moving in A with speeds due to a fall from L, and then if they form at any time the angular points of a polygon whose sides touch B they will continue to do so throughout the motion. Fig. 44 shows two forms of a quadrilateral possessing this property.

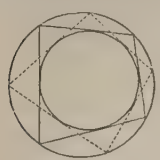

Fig. 44.

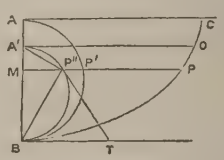

Fig. 45.

Cycloidal motion.

§ 137. *To find the time of fall from rest down any arc of an inverted cycloid.*

Let O (fig. 45) be the point from which the particle commences its motion. Draw OA′ parallel to CA, and on BA′ describe a semicircle. Let P, P′, P″ be corresponding points of the curve, the generating circle, and the circle just drawn, and let us compare the speeds of the particle at P and the point P″. Let P″T be the tangent at P″.

$$\frac{\text{Speed of P″}}{\text{Speed of P}} = \frac{\text{element at P″}}{\text{element at P}}$$

$$= \frac{\text{P″T}}{\text{BP″}} = \frac{\text{P″T}}{\text{BP″}}\sqrt{\frac{\text{A′B}}{\text{AB}}} = \frac{\text{A′B}}{2\text{A′P″}}\sqrt{\frac{\text{A′B}}{\text{AB}}}.$$

But speed of $\text{P} = \sqrt{(2g \cdot \text{A′M})} = \sqrt{\frac{2g}{\text{A′B}}} \cdot \text{A′P″}$.

Hence speed of $\text{P″} = \sqrt{\frac{g}{2\text{AB}}} \cdot \text{A′B}$, a constant.

And, as the length of A′P″B is $\frac{1}{2}\pi \cdot$ A′B,

time from A′ to B in circle = time from O to B in cycloid

$$= \pi\sqrt{\frac{\text{AB}}{2g}}.$$

Tautochrone.

The time of fall to the vertex from all points of the curve is therefore the same. Hence the cycloid is called a "tautochrone."

Resisted motion of pendulum.

§ 138. As an instance of cases in which the acceleration depends upon the speed and the position jointly, take the motion of a simple pendulum in a medium whose resistance varies as the velocity directly. This is the law, at least approximately, for very small speeds, whether the pendulum oscillate in a gas or in a liquid,—and even when the resistance is due to magneto-electric induction, as when the pendulum is a magnetic needle vibrating in presence of a conducting plate or a closed coil. A synthetical solution of this problem has already been given under Kinematics in § 68.

Analytically: if $l$ be the length of the string, $\theta$ its deflexion from the vertical at time $t$, $m$ the mass of the bob, we have evidently

$$ml\ddot{\theta} = -mg\sin\theta - \kappa\dot{\theta}.$$

The ratio $\kappa/ml$ may be increased (theoretically) without limit by increasing the surface which the bob exposes, without changing its mass. But it cannot be indefinitely diminished. We will write $2k$ for it. If we assume the angle of oscillation to be small, we may write the equation in the form

$$\ddot{\theta} + 2k\dot{\theta} + n^2\theta = 0,$$

where $n^2 = g/l$, and $k$ is essentially positive, being greater as the resistance (whether on account of the viscosity of the medium or the large surface of the bob in proportion to its mass) is greater. A particular integral of this equation is evidently

$$\theta = \varepsilon^{pt};$$

provided

$$p^2 + 2kp + n^2 = 0,$$

or

$$p = -k \pm \sqrt{k^2 - n^2}.$$

Hence there are two quite distinct cases of motion, distinguished by different *forms* of solution, depending on the relative magnitudes of $k$ and $n$. These are separated from one another by the unique case in which $k = n$.

(*a*) Let $k > n$, and let $k^2 - n^2 = n'^2 < k^2$.

Then both values of $p$ are real and negative. Thus

$$\theta = \text{A}\varepsilon^{p_1 t} + \text{B}\varepsilon^{p_2 t}$$

$$= \varepsilon^{-kt}(\text{A}\varepsilon^{n't} + \text{B}\varepsilon^{-n't}).$$

If A and B have the same sign, $\theta$ diminishes, without changing sign, as $t$ increases. But if A and B have different signs, the factor in brackets may vanish for one definite value of $t$, and then change sign. After that the whole reaches a maximum and then diminishes without further change of sign. Examples of these cases are furnished—(1) when the pendulum is displaced from the vertical and allowed to fall back; it then approximates asymptotically to its position of equilibrium; and (2) when it is drawn aside and flung back; in this case it may pass once through the position of equilibrium and then asymptotically return to it.

(*b*) Let $n > k$ and let $n^2 - k^2 = n'^2 < n^2$.

Here both values of $p$ are imaginary, and we have

$$\theta = \varepsilon^{-kt}(\text{A}\varepsilon^{+n't\sqrt{-1}} + \text{B}\varepsilon^{-n't\sqrt{-1}})$$

$$= \text{P}\varepsilon^{-kt}\cos(n't + \text{Q}),$$

This may be looked upon as a "simple harmonic motion" (§ 52), of which the amplitude diminishes in a geometric ratio with the time, the decrement depending on the resistance alone, while the period is permanently lengthened in the ratio $n : n'$. This ratio depends both upon the original period and the resistance, so that for the same medium and same bob it is different for strings of different lengths. This investigation gives an approximation to the gradual dying away (by internal friction or by imperfect elasticity, &c.) of all vibratory movements. The rate of diminution of amplitude, say of torsional vibrations of a wire, is thus a valuable indication and measure of a somewhat recondite physical quantity, which, without this method, would (at present at least) be hard to measure.

(*c*) When $n = k$, *i.e.*, in the transition case, the equation becomes

$$\ddot{\theta} + 2n\dot{\theta} + n^2\theta = 0;$$

whose integral is known to be

$$\theta = \varepsilon^{-nt}(\text{A} + \text{B}t) = \varepsilon^{-kt}(\text{A} + \text{B}t).$$

This, also, ultimately diminishes indefinitely as $t$ increases; but, as in case (*a*), it may either do so continuously or after having once passed through the value zero and reached a maximum, according to the relative magnitude and the signs of A and B.

§ 139. When the path is given, the determination of the motion under given forces is, as we have seen, a mere question of integration of the equation for acceleration along the tangent. But more is required if we wish to find the normal pressure on the constraining curve. This is at once supplied by compounding the resolved part of the applied forces in the direction perpendicular to the tangent, with the additional force $m\text{V}^2/\rho$ acting *from* the centre of curvature. But, strictly speaking, all such questions require the application of Law III.

*Kinetics of a Particle with Two Degrees of Freedom.*

§ 140. The simplest case is that of a projectile, when gravity is supposed to be uniform and to act in parallel lines throughout the whole path, and the resistance of the air is neglected. This has been sufficiently discussed in §§ 40–42. It is merely the combination of (1) the uniformly accelerated motion of a stone let fall, with (2) a uniform velocity in a definite direction. Looked at from this point of view, it gives an interesting example of the graphic method applied in § 53 to indicate the nature of simple harmonic motion. Projectile unresisted

§ 141. We can extend these projectile results so as to take account of the alteration of direction and of intensity

Elliptic motion of projectile.

of gravity at different points of the path, by remembering that, as shown in § 49, the path of an unresisted projectile is an ellipse, one of whose foci is at the centre of the earth. The following, among many other analogous propositions, are easily proved.

(1) The locus of the second foci of the paths of all projectiles leaving a given point with a given speed, in a vertical plane, is a circle.

(2) The direction of projection, for the greatest range on a given line passing through the point of projection, bisects the angle between the vertical and the line.

(3) Any other point on the line which can be reached at all can be reached by two different paths, and the directions of projection for these are equally inclined to the direction which gives the maximum range.

(4) If a projectile meet the line at right angles, the point which it strikes is the vertex of the other path by which it may be reached.

(5) The envelop of all possible paths in a vertical plane is an ellipse, one of whose foci is the centre of the earth, and the other the point of projection.

To prove these propositions, let E (fig. 46) be the earth's centre, P the point of projection, A the point which the projectile would reach if fired vertically upwards. With centre E, and radius EA, describe a circle in the common plane of projection. This, the circle of zero velocity, corresponds to the common directrix of the parabolic paths in the ordinary theory. If F be the second focus of any path, we must have EP + PF constant, because the axis major depends on the speed, not the direction, of projection. Hence (1) the locus of F is the circle AFO, centre P. Again, since, if F be the focus of the path which meets PR in Q, we must have FQ = QS, it is obvious that the greatest range P$q$ is to be found by the condition O$q$ = $qs$. O is therefore the second focus of this trajectory, and therefore (2) the direction of projection for the greatest range on PR bisects the angle APR. If QF = QF′ = QS, F and F′ are the second foci of the two paths by which Q may be reached; and, as ∠ F′PO = ∠ FPO, we see the truth of (3). If Q be a point reached by the projectile when moving in a direction perpendicular to PR, we must evidently have ∠ PQF′ = ∠ PQF = ∠ SQR = ∠ EQP; *i.e.*, EQ passes through F′. When this is the case, the ellipse whose second focus is F evidently meets PR at right angles; and that whose second focus is F′ has (4) its vertex at Q. The locus of $q$ is evidently the envelop of all the trajectories. Now

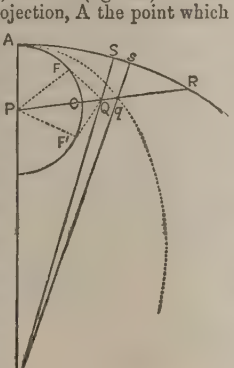

Fig. 46.

$$Pq = PO + Oq = PA + Oq,$$
$$Eq = Es - sq = EA - Oq.$$

Hence

$$Pq + Eq = PA + AE,$$

or (5) the envelop is an ellipse, whose foci are E and P, and which passes through A.

Planetary motion.

§ 142. One of the most important problems in this branch of our subject is that of planetary motion, which forms a good typical example of the processes to be employed in the treatment of central orbits. One or two definitions, and a general property of central orbits, must be premised.

Apse.

§ 143. *Def.* An "apse" is a point, in a central orbit, at which the path is perpendicular to the radius-vector along which the central force acts.

The length of the radius-vector is therefore, at such a point, generally a maximum or a minimum. This radius vector, drawn to an apse, is called an "apsidal line."

*A central orbit is symmetrical about every apsidal line.* The simplest proof of this theorem depends upon the general principle of "reversibility," which holds in all conservative systems. In fact if, at any instant, the velocity-vector of a particle, moving under the action of a conservative system of forces, be reversed, the particle will simply retrace its previous path. For if we suppose a smooth tube, in the form of the previous path, to be employed to guide it back, the speed at every point will be of the same magnitude as before. The curvature also of the path will be the same; and thus the normal component of the applied forces will balance the so-called centrifugal force,—*i.e.*, will suffice to produce the requisite curvature,—so that there will be no pressure on the tube, and it is not required. Hence since, at an apse, the velocity is perpendicular to the radius-vector, the two halves of the orbit on opposite sides of the apsidal line are similar and equal. Hence, however many apses there may be, there can be at most only two apsidal distances. For the property of symmetry about each apsidal line shows that, if there be more apses than one, the first, third, fifth, &c., must have their apsidal distances equal, as also must the second, fourth, sixth, &c. If there be one apse only, it may correspond either to a minimum or to a maximum value of the radius-vector; but, if there be more than one, they must be maxima and minima alternately.

§ 144. We now proceed to the gravitation case already promised. We will take, first, the direct problem as in § 49, where the force is assigned and the orbit is to be found.

Planetary motion.

*A particle is projected from a given point in a given direction and with a given speed, and moves under the action of a central attraction varying inversely as the square of the distance; to determine the orbit.*

We have $P = \mu u^2$, and therefore by the last part of § 47

$$\frac{d^2u}{d\theta^2} + u - \frac{\mu}{h^2} = 0,$$

where $h$ is double the constant area, or

$$\frac{d^2}{d\theta^2}\left(u - \frac{\mu}{h^2}\right) + \left(u - \frac{\mu}{h^2}\right) = 0,$$

the integral of which is

$$u - \frac{\mu}{h^2} = A\cos(\theta + B),$$

or, as it is usually written,

$$u = \frac{\mu}{h^2}\left\{1 + e\cos(\theta - \alpha)\right\} \quad . \quad . \quad . \quad . \quad . \quad (1).$$

This gives by differentiation

$$\frac{du}{d\theta} = -\frac{\mu}{h^2}e\sin(\theta - \alpha) \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Let R be the distance of the point of projection from the centre, and $\beta$ the angle, and V the speed, of projection; then, when $\theta = 0$,

$$u = \frac{1}{R}, \quad \cot\beta = -\left(\frac{1}{u}\frac{du}{d\theta}\right)_{\theta=0}.$$

Hence, by (1)
$$\frac{h^2}{\mu R} - 1 = e\cos\alpha,$$

and by (2)
$$\frac{h^2}{\mu R}\cot\beta = -e\sin\alpha.$$

From these
$$\tan\alpha = \frac{h^2\cot\beta}{\mu R - h^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

and
$$e^2 = \frac{h^4}{\mu^2R^2}\operatorname{cosec}^2\beta - \frac{2h^2}{\mu R} + 1 \quad . \quad . \quad . \quad . \quad (4).$$

But
$$h^2 = V^2R^2\sin^2\beta,$$

wherefore
$$\tan\alpha = \frac{V^2R\sin\beta\cos\beta}{\mu - V^2R\sin^2\beta} \quad . \quad . \quad . \quad . \quad (3'),$$

and
$$1 - e^2 = \frac{V^2R^2\sin^2\beta}{\mu}\left(\frac{2}{R} - \frac{V^2}{\mu}\right) \quad . \quad . \quad . \quad . \quad (4').$$

Now (1) is the general polar equation of a conic section, focus the pole, and, as its nature depends on the value of the excentricity $e$ given by (4), we see that

if $V^2 > 2\mu/R$, $e > 1$, and the orbit is an hyperbola;
if $V^2 = 2\mu/R$, $e = 1$, and the orbit is a parabola;
if $V^2 < 2\mu/R$, $e < 1$, and the orbit is an ellipse.

But the square of the speed from rest at infinity to distance R, for the law of attraction we are considering, is $2\mu/R$, and the above conditions may therefore be expressed more concisely by saying that the orbit will be an hyperbola, a parabola, or an ellipse, according as the speed of projection is greater than, equal to, or less than, the speed from infinity. Illustrations of this proposition are found in the cases of comets and of meteor swarms.

The speed of a particle moving in a circle is also often taken as the standard of comparison for estimating the velocities of bodies in their orbits. For the gravitation law of attraction the square of the speed in a circle of radius R is $\mu/R$; and the above conditions may be expressed in another form by saying that the orbit will be an hyperbola, a parabola, or an ellipse, according as the speed of projection is greater than, equal to, or less than $\sqrt{2}$ times the speed in a circle at the same distance.

Supposing the orbit to be an ellipse, we shall obtain its major axis and latus rectum most easily by a different process of integrating the differential equation. Multiplying it by $h^2\frac{du}{d\theta}$ and integrating, we obtain

$$\frac{1}{2}h^2\left\{\left(\frac{du}{d\theta}\right)^2 + u^2\right\} = -\frac{1}{2}v^2 = C + \mu u.$$

But when $u = \frac{1}{R}$, $v = V$; which gives

$$C = \frac{1}{2}V^2 - \frac{\mu}{R};$$

hence
$$\frac{1}{2}h^2\left\{\left(\frac{du}{d\theta}\right)^2 + u^2\right\} = -\frac{1}{2}v^2 = -\frac{1}{2}V^2 - \frac{\mu}{R} + \mu u \quad . \quad . \quad (5).$$

Now to determine the apsidal distances, we must put

$$\frac{du}{d\theta} = 0;$$

and this gives us the condition

$$u^2 - \frac{2\mu}{h^2}u + \frac{2\mu}{h^2R} - \frac{V^2}{h^2} = 0 \quad . \quad . \quad . \quad . \quad . \quad (6),$$

which is a quadratic equation whose roots are the reciprocals of the two apsidal distances. But if $a$ be the semi-axis major, and $e$ the excentricity, these distances are

$$a(1-e) \text{ and } a(1+e).$$

Hence, as the coefficient of the second term of (6) is the sum of the roots with their signs changed, we have

$$\frac{1}{a(1-e)} + \frac{1}{a(1+e)} = \frac{2\mu}{h^2};$$

or
$$a(1-e^2) = \frac{h^2}{\mu} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7).$$

And the third term is the product of the roots, so that

$$\frac{1}{a^2(1-e^2)} = \frac{2\mu}{h^2R} - \frac{V^2}{h^2};$$

or, by (7),
$$\frac{1}{a} = \frac{2}{R} - \frac{V^2}{\mu} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8).$$

Thus
$$\frac{1}{2}V^2 = \frac{\mu}{R} - \frac{\mu}{2a},$$

and therefore
$$\frac{1}{2}v^2 = \frac{\mu}{r} - \frac{\mu}{2a} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9).$$

Equations (7) and (8) give the latus rectum and major axis of the orbit, and show that the major axis is independent of the direction of projection.

Equation (9) gives a useful expression for the speed at any point, and shows that the radius of the circle of zero speed is $2a$.

The time of describing any given angle is to be obtained from the formula,

$$r^2\frac{d\theta}{dt} = h = \sqrt{\{\mu a(1-e^2)\}}, \text{ by equation (7).}$$

From this, combined with the polar equation of the ellipse about the focus, we have

$$\frac{dt}{d\theta} = \frac{r^2}{\sqrt{\{\mu a(1-e^2)\}}} = \sqrt{\left(\frac{a^3(1-e^2)^3}{\mu}\right)}\frac{1}{(1+e\cos\theta)^2},$$

measuring the angle from the nearer apse.

Integrating, we find the time of describing about the focus an angle $\theta$ measured from the nearer apse, in the ellipse or hyperbola, expressed as $2/h$ of the sectorial area ASP (figure to § 147), which might have been written down from the condition of uniform moment of momentum.

In the parabola, if $d$ be the apsidal distance, the integral becomes

$$\left[\text{since } e = 1,\ a(1-e) = d,\ a(1-e^2) = 2d\right],$$

$$t = \sqrt{\frac{2d^3}{\mu}}\left(\tan\frac{\theta}{2} + \frac{1}{3}\tan^3\frac{\theta}{2}\right).$$

From the result for the ellipse we see that the periodic time is

$$2\pi\sqrt{a^3/\mu}.$$

In the notation commonly employed for the further development of this most important question we write

$$T = 2\pi/n,$$

where $n$, which is called the "mean motion," is $\sqrt{\mu/a^3}$.

Kepler's laws (kinematical.

§ 145. By laborious calculation from an immense series of observations of the planets, and of Mars in particular, Kepler was led to enunciate the following as the kinematical laws of the planetary motions about the sun.

I. The planets describe, relatively to the sun, ellipses of which the sun occupies a focus.

II. The radius vector of each planet traces out equal areas in equal times.

III. The squares of the periodic times of any two planets are as the cubes of the major axes of their orbits.

Consequences of Kepler's laws.

§ 146. We proceed to the *inverse* problem of § 8 (*b*), the determination of the force from the observed motions.

From the second of the above laws we conclude that the planets are retained in their orbits by an attraction tending to the sun. *If the radius-vector of a particle moving in a plane describe equal areas in equal times about a point in that plane, the resultant attraction on the particle tends to that point.* For the datum is equivalent to the statement that there is no change of moment of momentum about the sun, or that the accelerations all pass through the sun viewed as a point.

From the first law it follows that the law of the intensity of the attraction is that of the inverse square of the distance.

The polar equation of an ellipse referred to its focus is

$$u = \frac{2}{l}(1 + e\cos\theta)$$

where $l$ is the latus rectum.

Hence
$$\frac{d^2u}{d\theta^2} = -\frac{2e}{l}\cos\theta,$$

and therefore the attraction to the focus requisite for the description of the ellipse is (§ 47)

$$P = h^2u^2\left(\frac{d^2u}{d\theta^2} + u\right) = \frac{2h^2}{l}u^2.$$

*Hence, if the orbit be an ellipse described about a centre of attraction at the focus, the law of intensity is that of the inverse square of the distance.*

From the third law it follows that the attraction of the sun (supposed fixed) which acts on unit of mass of each of the planets is the same for each planet at the same distance.

For, in the last formula in § 144, $T^2$ will not vary as $a^3$ unless $\mu$ be constant, *i.e.*, unless the strength of attraction of the sun be the same for all the planets.

Law of gravitation (physical).

We shall find afterwards that for more reasons than one Kepler's laws are only approximate, but their enunciation was sufficient to enable Newton to propound the doctrine of universal gravitation, viz., that *every particle of matter in the universe attracts every other with an attraction whose direction is that of the line joining them, and whose magnitude is as the product of the masses directly and as the square of the distance inversely*; or, according to Maxwell's formulation, *between every pair of particles there is a stress of the nature of a tension, proportional to the product of the masses of the particles divided by the square of their distance.*

If we take into account that the sun is not absolutely fixed, then, neglecting the mutual attractions of the planets, Kepler's third law should be stated thus:—

*The cubes of the major axes of the orbits are as the squares of the periodic times and the sums of the masses of the sun and the planet.*

Calculation of planet's motion.

**§ 147.** We will now indicate, as briefly as possible, the more ordinary transformations by which the preceding formulæ are adapted (for astronomical applications) to numerical calculation.

Suppose APA′ (fig. 47) to be an elliptic orbit described about a centre of attraction in the focus S. Also suppose P to be the position of the particle at any time $t$. Draw PM perpendicular to the major axis ACA′, and produce it to cut the auxiliary circle in the point Q. Let C be the common centre of the curves. Join CQ.

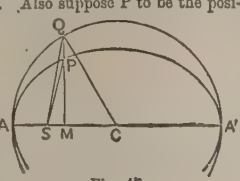

Fig. 47.

When the moving particle is at A, the nearest point of the orbit to S, it is said to be in "perihelion."

The angle ASP, or the excess of the particle's longitude over that of the perihelion, is called the "true anomaly." Let us denote it by $\theta$.

The angle ACQ is called the "excentric anomaly," and is generally denoted by $u$. And, if $2\pi/n$ be the time of a complete revolution, $nt$ is the circular measure of an imaginary angle called the "mean anomaly;" it would evidently be the true anomaly if the particle's angular velocity about S were constant.

It is easy from known properties of the ellipse to deduce the following relations between the mean and excentric, and also between the true and excentric, anomalies:—

$$nt = u - e\sin u.$$

$$\tan\frac{u}{2} = \sqrt{\left(\frac{1-e}{1+e}\right)}\tan\frac{\theta}{2}.$$

By far the most important problem is to find the values of $\theta$ and $r$ as functions of $t$, so that the direction and length of a planet's radius-vector may be determined for any given time. This generally goes by the name of Kepler's Problem.

Before indicating the systematic development of $u$, $r$, and $\theta$ in terms of $t$ from our equations, it may be useful to remark that, if $e$ be so small that higher terms than its square may be neglected, we may easily obtain developments correct to the first three terms. Thus

$$\begin{aligned} u &= nt + e\sin u, \\ &= nt + e\sin(nt + e\sin nt) \text{ nearly}, \\ &= nt + e\sin nt + \tfrac{1}{2}e^2\sin 2nt. \end{aligned}$$

Also

$$\begin{aligned} \frac{r}{a} &= 1 - e\cos u, \\ &= 1 - e\cos(nt + e\sin nt), \\ &= 1 - e\cos nt + \tfrac{1}{2}e^2(1 - \cos 2nt). \end{aligned}$$

And

$$r^2\frac{d\theta}{dt} = \sqrt{\{\mu a(1-e^2)\}},$$

which may be written

$$\frac{a^2(1-e^2)^2}{(1+e\cos\theta)^2}\frac{d\theta}{dt} = na^2(1-e^2)^{\frac{1}{2}},$$

or

$$(1-e^2)^{\frac{1}{2}}(1+e\cos\theta)^{-2}\frac{d\theta}{dt} = n.$$

Keeping powers of $e$ lower than the third,

$$\left(1 - 2e\cos\theta + \tfrac{3}{2}e^2\cos 2\theta\right)\frac{d\theta}{dt} = n,$$

or

$$nt = \theta - 2e\sin\theta + \tfrac{3}{4}e^2\sin 2\theta;$$

whence

$$\begin{aligned} \theta &= nt + 2e\sin\theta - \tfrac{3}{4}e^2\sin 2\theta, \\ &= nt + 2e\sin(nt + 2e\sin nt) - \tfrac{3}{4}e^2\sin 2nt, \\ &= nt + 2e\sin nt + 4e^2\cos nt\sin nt - \tfrac{3}{4}e^2\sin 2nt, \\ &= nt + 2e\sin nt + \tfrac{5}{4}e^2\sin 2nt. \end{aligned}$$

Kepler's problem.

KEPLER'S PROBLEM.—*To find $r$ and $\theta$ as functions of $t$ from the equations*

$$r = a(1 - e\cos u) \quad \ldots\ldots (1);$$

$$\tan\frac{\theta}{2} = \sqrt{\frac{1+e}{1-e}}\tan\frac{u}{2} \quad \ldots\ldots (2),$$

$$nt = u - e\sin u \quad \ldots\ldots (3).$$

These equations evidently give $r$, $\theta$, and $t$ directly for any assigned value of $u$, but this is of little value in practice. The method of solution which is commonly adopted is that of Lagrange, and the general principle of it is this:—

We can develop $\theta$ from equation (2) in a series ascending by powers of a small quantity, $e$, the coefficients of these powers involving $u$ and the sines of multiples of $u$. Now by Lagrange's theorem we may from equation (3) express $u$, $1 - e\cos u$, $\sin u$, $\sin 2u$, &c., in series ascending by powers of $e$, whose coefficients are sines or cosines of multiples of $nt$. Hence, by substituting these values in equation (1) and in the development of (2), we have $r$ and $\theta$ expressed in series whose terms rapidly decrease, and whose coefficients are sines or cosines of multiples of $nt$. This is the complete practical solution of the problem. But we must refer the reader to special treatises for the full development of this subject. Compare § 52.

Stability of circular orbit.

**§ 148.** We may take an opportunity here of giving a sketch of a particular case of the important question of "kinetic stability." The general treatment of this subject is entirely beyond our limits. But we may investigate its conditions, in the case of a central orbit naturally circular, by a very slight modification of our equations.

Whatever be the law of central force, provided it depend on the distance alone, we can write the acceleration due to it as

$$\mu u^2 f(u),$$

where $u$ is the now reciprocal of the radius-vector, as in § 144. The kinematics of the motion is then entirely summed up in the equations

$$\frac{d^2u}{d\theta^2} + u = \frac{\mu}{h^2}f(u), \text{ and } \frac{d\theta}{dt} = hu^2.$$

If $1/a$ be the radius of the circle, the first equation becomes simply

$$a = \frac{\mu}{h^2}f(a).$$

Now let a slight disturbance be given to the motion, such that $h$ is unaltered, but that $u$ becomes $a+x$. Then we have

$$\frac{d^2x}{d\theta^2} + a + x = \frac{\mu}{h^2}f(a+x).$$

Expanding to first powers of $x$ only, and thereby assuming that $x$ is always exceedingly small, we have

$$\frac{d^2x}{d\theta^2} + x\left(1 - \frac{\mu}{h^2}f'(a)\right) = 0,$$

the terms independent of $x$ vanishing by the condition for a circular orbit. By eliminating the ratio $\mu/h^2$ we have

$$\frac{d^2x}{d\theta^2} + x\left(1 - \frac{af'(a)}{f(a)}\right) = 0.$$

To secure stability, $x$ must not be capable of increasing indefinitely. This leads to the result that the multiplier of $x$ in the above equation must be positive; *i.e.*,

$$1 - \frac{af'(a)}{f(a)} > 0.$$

For, if the multiplier were negative, the value of $x$ would consist of two real exponential terms, one of which would increase indefinitely with the angle $\theta$, and would disappear from the value of $x$ under special conditions only.

If the multiplier were zero, $x$ would be a linear function of $\theta$. Hence, in the only case we need consider, we have

$$x = A\cos\left(\theta\sqrt{1 - \frac{af'(a)}{f(a)}} + B\right).$$

The radius-vector is therefore a maximum and minimum (*i.e.*, apses occur) alternately as the angle $\theta$ increases by successive increments each equal to

$$\frac{\pi}{\sqrt{1 - \dfrac{af'(a)}{f(a)}}}.$$

Suppose the force to vary as the inverse $n$th power of the distance. Here $f(a) \propto a^{n-2}$, and we have $1 - \dfrac{af'(a)}{f(a)} = 1 - (n-2) = 3 - n$. Thus $n$ must be less than 3; *i.e.*, a circular orbit, with the centre of force in the centre, is essentially unstable if the force vary as the inverse third, or any higher inverse power of the distance.

If $n = 2$, which is the gravitation case, the apsidal angle is evidently $\pi$.

Newton's revolving orbit.

**§ 149.** A very curious result, due to Newton, may be indicated here, viz., that, if any central orbit be made to revolve in its own plane with angular velocity proportional at each instant to that of the radius-vector in the fixed orbit, it will still be a central orbit; and the additional force required will be inversely as the cube of the radius-vector.

Generally, in a central orbit,

$$\ddot{r} - r\dot{\theta}^2 = \mathrm{P}. \qquad r^2\dot{\theta} = h,$$

But suppose $\theta$ to become $c\theta_1$, where $c$ is a constant, and we have

$$\theta = c\theta_1,$$

which is Newton's hypothesis. The above equations become

$$\ddot{r} - r\dot{\theta}_1^2 = P + (c^2-1)r\dot{\theta}_1^2, \quad r^2\dot{\theta}_1 = h;$$

or, as they may be written,

$$\ddot{r} - r\dot{\theta}_1^2 = P + (c^2-1)h_1^2/r^3, \quad r^2\dot{\theta}_1 = h_1.$$

From these the proposition is obvious.

Other examples of central orbits will be given when we discuss general principles, such as "least action" and "varying action."

*Special Problem. The Brachistochrone.*

Brachistochrone.

§ 150. A celebrated problem in the history of dynamics is that of the "curve of swiftest descent," as it was called:—

*Two points being given, which are neither in a vertical nor in a horizontal line, to find the curve joining them down which a particle sliding under gravity, and starting from rest at the higher, will reach the other in the least possible time.*

The curve must evidently lie in the vertical plane passing through the points. For suppose it not to lie in that plane, project it orthogonally on the plane, and call corresponding elements of the curve and its projection $\sigma$ and $\sigma'$. Then if a particle slide down the projected curve its speed at $\sigma'$ will be the same as the speed in the other at $\sigma$. But $\sigma$ is *never less* than $\sigma'$, and is generally greater. Hence the time through $\sigma'$ is generally less than that through $\sigma$, and *never greater*. That is, the whole time of falling through the projected curve is less than that through the curve itself. Or the required curve lies in the vertical plane through the points.

Also it is easy to see that, if the time of descent through the entire curve is a minimum, that through any portion of the curve is less than if that portion were changed into any other curve.

Conditions for a maximum.

And it is obvious that, *between any two contiguous equal values of a continuously varying quantity, a maximum or minimum must lie.* [This principle, though excessively simple (witness its application to the barometer or thermometer), is of very great power, and often enables us to solve problems of maxima and minima, such as require, in analysis, not merely the processes of the differential calculus but those of the calculus of variations. The present is a good example.]

Let, then, PQ, QR and PQ', Q'R (fig. 48) be two pairs of indefinitely small sides of polygons such that the time of descending through either pair, starting from P with a given speed, may be equal. Let QQ' be horizontal, and indefinitely small compared with PQ and QR. The brachistochrone must lie between these paths, and must possess any property which they possess in common. Hence if $v$ be the speed down PQ (supposed uniform) and $v'$ that down QR, drawing $Qm$, $Q'n$ perpendicular to RQ', PQ, we must have

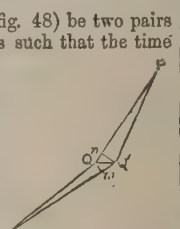

Fig. 48.

$$\frac{Qn}{v} = \frac{Q'm}{v'}.$$

Now if $\theta$ be the inclination of PQ to the horizon, $\theta'$ that of QR, $Qn = QQ'\cos\theta$, $Q'n = QQ'\cos\theta'$. Hence the above equation becomes

$$\frac{\cos\theta}{v} = \frac{\cos\theta'}{v'}.$$

This is true for any two consecutive elements of the required curve; and therefore throughout the curve

$$v \propto \cos\theta.$$

But $v^2 \propto$ vertical distance fallen through (§ 28). Hence the curve required is such that the cosine of the angle it makes with the horizontal line through the point of departure varies as the square root of the distance from that line,—which is easily seen to be a property of the cycloid, if we remember that the tangent to that curve is parallel to the corresponding chord of its generating circle. For in fig. 45, § 137,

$$\cos BP'M = \cos BAP' = \frac{AP'}{AB} = \sqrt{\frac{AM}{AB}} \propto \sqrt{AM}.$$

The brachistochrone then, under gravity, is an inverted cycloid whose cusp is at the point from which the particle descends.

§ 151. Whatever be the impressed forces, reasoning similar to that in last section would show that the osculating plane of the brachistochrone always contains the resultant force, and that

$$v'\cos\theta = v\cos\theta',$$

where $\theta$ is now the complement of the angle between the curve and the resultant of the impressed forces.

Let that resultant = F, and let the element PQ = $\delta s$, and $\theta' = \theta + \delta\theta$. Then

$$v'^2 - v^2 = 2F\delta s\sin\theta,$$

or

$$v\delta v = F\delta s\sin\theta.$$

But $v \propto \cos\theta$; which gives

$$\frac{\delta v}{v} = -\frac{\sin\theta}{\cos\theta}\delta\theta.$$

Hence

$$v^2/\frac{\delta s}{\delta\theta} = -F\cos\theta.$$

But in the limit $\frac{\delta s}{\delta\theta} = \rho$, the radius of absolute curvature at Q; and $F\cos\theta$ is the normal component of the impressed force. Hence we obtain the result that, in any brachistochrone, the pressure on the curve is double of that due to the force acting.

§ 152. Now for the unconstrained path from P to R we have $\int v ds$ a minimum (§ 262). Hence in the same way as before, $\phi$ being the angle corresponding to $\theta$, $v\cos\phi = v'\cos\phi'$ from element to element, and therefore throughout the curve, if the direction of the force be constant. Now, if the velocities in the unconstrained and brachistochrone paths be equal at any equipotential surface, they will be equal at every other. Hence, taking the angles for any equipotential surface,

$$\cos\theta\cos\phi = \text{constant}.$$

As an example, suppose a parabola with its vertex upwards to have for directrix the base of an inverted cycloid; these curves evidently satisfy the above condition, the one being the free path, the other the brachistochrone, for gravity, and the velocities being in each due to the same horizontal line. And it is seen at once that the product of the cosines of the angles which they make with any horizontal straight line which cuts both is a constant whose magnitude depends on those of the cycloid and parabola, its value being $\sqrt{l/4a}$, where $l$ is the latus rectum of the parabola, and $a$ the diameter of the generating circle of the cycloid.

*Kinetics of a Particle Generally.*

General examples.

§ 153. Here we must content ourselves with a few special cases, which will be varied as much as possible.

*A unit particle moves on a smooth curve, under the action of any system of forces; find the motion.*

All we know directly about the pressure R on the curve is that it is perpendicular to the tangent line at any point.

Resolve then the given forces acting upon the particle into three,—one, T, along the tangent, which in all cases in nature will be a function of $x$, $y$, $z$ and therefore of $s$; another, N, in the line of intersection of the normal and osculating planes (or radius of absolute curvature); and the third, P, perpendicular to the osculating plane.

Let the resolved parts of R in the directions of N and P be $R_1$, $R_2$. Now the acceleration of a point moving in any manner is compounded of two accelerations, one $\frac{d^2s}{dt^2}$ or $v\frac{dv}{ds}$ along the tangent to the path, and the other $\frac{v^2}{\rho}$ towards the centre of absolute curvature, the acceleration perpendicular to the osculating plane being zero; and therefore

$$\frac{d^2s}{dt^2} = T \quad \ldots\ldots\ldots \quad (1),$$

This equation, together with the two equations of the curve, is sufficient to determine the motion completely.

Also
$$\frac{v^2}{\rho}=R_1+N \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

$R_1$ and N being considered positive when acting towards the centre of absolute curvature; this equation determines $R_1$.

Now $R_2$ is the reaction which prevents P's withdrawing the particle from the osculating plane; and therefore

$$R_2=-P \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

(2) and (3) give the resolved parts of the pressure on the curve. Also $R=\sqrt{(R_1^2+R_2^2)}$, and its direction makes an angle $=\tan^{-1}(R_2/R_1)$ with the osculating plane.

If the result of the investigation should show that at any time R could vanish, the particle must be treated as free until the equations of its free motion show that it is again in contact with the curve.

Particle on smooth surface.

*A particle moves, under given forces, on a given smooth surface, to determine the motion, and the pressure on the surface.*

Let
$$F(x, y, z)=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

be the equation of the surface, R the reaction, acting in the normal to the surface, which is the only effect of the constraint. Then, if $\lambda$, $\mu$, $\nu$ be its direction cosines, we know that

$$\lambda=\frac{\left(\frac{dF}{dx}\right)}{\sqrt{\left\{\left(\frac{dF}{dx}\right)^2+\left(\frac{dF}{dy}\right)^2+\left(\frac{dF}{dz}\right)^2\right\}}} \qquad (2),$$

with similar expressions for $\mu$ and $\nu$, the differential coefficients being partial.

If X, Y, Z be the applied forces on unit of mass, our equations of motion are, evidently,

$$\left.\begin{aligned}\ddot{x}&=X+R\lambda\\ \ddot{y}&=Y+R\mu\\ \ddot{z}&=Z+R\nu\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

**Multiplying** equations (3) respectively by $\dot{x}$, $\dot{y}$, $\dot{z}$, and adding, we obtain

$$\dot{x}\ddot{x}+\dot{y}\ddot{y}+\dot{z}\ddot{z}=v\dot{v}=X\dot{x}+Y\dot{y}+Z\dot{z} \quad . \quad . \quad . \quad . \quad (4).$$

R disappears from this equation, for its coefficient is

$$\lambda\dot{x}+\mu\dot{y}+\nu\dot{z}$$

and vanishes, because the line whose direction cosines are proportional to $\dot{x}$, &c., being the tangent to the path, is perpendicular to the normal to the surface.

If we suppose X, Y, Z to be a conservative system of forces, the integral of (4) will be of the form

$$\tfrac{1}{2}v^2=\phi(x, y, z)+C \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5),$$

and the velocity at any point will depend only on the initial circumstances of projection, and not on the form of the path pursued.

To find R, resolve along the normal, then

$$v^2/\rho=X\lambda+Y\mu+Z\nu+R,$$

which gives the reaction of the surface; $\rho$ being the radius of curvature of the normal section of the surface through the tangent to the path, and the mass of the particle being taken as unity.

*To find the curve which the particle describes on the surface.*

For this purpose we must eliminate R from equations (3). By this process we obtain

$$\frac{\ddot{x}-X}{\lambda}=\frac{\ddot{y}-Y}{\mu}=\frac{\ddot{z}-Z}{\nu} \quad . \quad . \quad . \quad . \quad . \quad . \quad (6),$$

two equations, between which if $t$ be eliminated, the result is the differential equation of a second surface intersecting the first in the curve described.

If there be no applied forces, or if the component of the applied force in the tangent plane coincide with the direction of motion of the particle, then the osculating plane of the path of the particle, which contains the resultant of R and the applied force, will be a normal plane, and therefore the path will be a geodesic on the surface.

Thus a particle under no forces on a smooth (or rough) surface will describe a geodesic.

Conical pendulum.

§ 154. An excellent and important example is furnished by the simple pendulum, when its vibrations are not confined to one vertical plane. When the bob moves in a horizontal plane, the arrangement is called a "conical" pendulum, and it is a very simple matter, as follows, to find the motion. For the vertical component of the tension of the string must support the weight of the bob; *i.e.*,

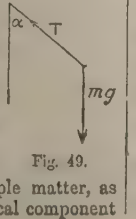

Fig. 49.

$$T\cos\alpha=mg,$$

where $\alpha$ is the inclination of the string to the vertical. Also the horizontal component of the tension must supply the force $mV^2/R$ (§ 49) requisite for the production of the curvature of the path, *i.e.*,

$$T\sin\alpha=m\frac{V^2}{l\sin\alpha}$$

Eliminating $m/T$ from these equations, we have

$$\frac{\cos\alpha}{\sin^2\alpha}=\frac{gl}{V^2}.$$

But, if $\tau$ be the time of revolution of the bob,

$$V\tau=2\pi l\sin\alpha.$$

Hence
$$\frac{\cos\alpha}{\tau^2}=\frac{gl}{4\pi^2l^2},$$

or
$$\tau=2\pi\sqrt{\frac{l\cos\alpha}{g}};$$

*i.e.*, the conical pendulum revolves in the period of the small vibrations of a simple pendulum whose length is the vertical component of that of the conical pendulum (§ 134).

To carry the investigation to cases in which the pendulum describes a tortuous curve, we require (except for approximate results) the use of elliptic functions. We thus obtain, among others, the following results:—

The motion will be comprised between two horizontal circles. Let the depths of these circles below the centre be $b+c$ and $b-c$; then the vertical motion of the bob of the pendulum will be the same as that of a point on a simple pendulum of length $l^2/c$ performing complete revolutions in the same periodic time as the spherical pendulum.

But for one of the most important applications the deflexion from the vertical is always very small, and it is easy to obtain a sufficiently accurate working approximation without the use of elliptic functions. If we put $p$ and $q$ for the semidiameters of the small elliptic orbit which will then be described by the pendulum bob, we find for the apsidal angle

$$\frac{\pi}{2}\left(1+\frac{3pq}{8a^2}+\ldots\right).$$

Hence, when a pendulum is slightly disturbed in any way, the motion is to a first approximation elliptic as in § 50. But the second approximation shows that this ellipse rotates in its own plane, and in the same sense as that in which it is described, with an angular velocity proportional to its area. Hence the necessity for extreme care, in making Foucault's experiment (presently to be described), lest the path should even slightly deviate from a vertical plane.

§ 155. Another very important and useful example is furnished by Blackburn's pendulum, which is simply a pellet supported by three threads or fine wires knotted together at one point C (fig. 50). The two other ends of two of them are attached to fixed points A and B, and the third supports the pellet P. The motion of P is virtually executed on a smooth surface, whose principal curvatures near the lowest point are 1/CP in the plane of the three threads, and 1/PE in the plane perpendicular to them,—E being the intersection of the vertical through C with the line AB. Hence for small disturbances of this system, P has a simple harmonic motion in the plane of the paper whose period is $2\pi\sqrt{CP/g}$, and another at right angles to it, with period $2\pi\sqrt{PE/g}$. The amplitudes of these motions are arbitrary, and, with the difference of phase, depend entirely on the initial disturbance. Thus we have a very simple mechanical means of producing the combinations treated in § 63; for we have only to make

Blackburn pendulum.

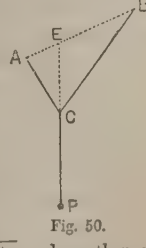

Fig. 50.

$$PE:PC::\omega^2:\omega'^2,$$

and give the bob its proper initial motion.

§ 156. When CE is very small compared with CP, we have a realization of the case of § 61, in which the

orbit is (at any instant) an ellipse, but in which the ellipse gradually changes its form and position, so as to be always inscribed in a definite rectangle. This experimental arrangement is exceedingly instructive. To avoid as far as may be the effects of resistance of the air, the vibrations should be slow, *i.e.*, the wires should be as long as possible. The bob should be a ball of lead, containing a tube full of ink which slowly escapes from a fine orifice at its lower end, so as to make a permanent record of the path on a sheet of paper placed below the plane of motion of the bob, but parallel and very close to it. Or, the bob may be furnished with a spike at its lower end, from which induction sparks may be taken so as to pierce a sheet of paper laid on a copper plate below it.

By mere alterations of the point of suspension A, the ratio of $\omega$, $\omega'$ may be varied at pleasure, provided that AC and BC are long enough compared with CP.

Lissajoux's tuning-forks.

§ 157. Lissajoux produced similar curves by attaching plane mirrors to the legs of tuning-forks, and allowing a ray of light, after successive reflexions from two such mirrors, to fall on a screen. But it seems to have been first pointed out much earlier by Sang, and afterwards developed by Wheatstone, that the same result is obtained by fixing firmly one end of a steel rod, and setting the free end in vibration. There are two planes of greatest and least flexural rigidity (§ 274) in all wires, however carefully drawn. These are at right angles to one another; and the motion of the free end of the wire when slightly disturbed is therefore precisely that of the bob of the Blackburn pendulum. Another interesting mode of producing the same result is by causing a ray of sunlight to be reflected in succession from four mirrors, all attached, nearly at right angles, to parallel axes. One pair is made to rotate, the two in opposite directions, with one angular velocity. A ray reflected in succession from these is (§ 65) made to oscillate according to the simple harmonic law, in a plane which can be varied at pleasure by altering the relative position of the normals to the two mirrors. The other pair of mirrors supplies the other simple harmonic motion, also in any desired plane.

Foucault pendulum.

§ 158. We must next consider the effect of the earth's rotation upon the motion of a simple pendulum. Strange to say it was left for Foucault to point out, in February 1851, that the plane of vibration of a simple pendulum suspended at either pole would *appear* to turn through four right angles in twenty-four hours,—the plane, in fact, remaining constant in position while objects beneath the pendulum were carried round by the diurnal rotation. At the equator, it was pretty obvious that no such effect would occur, at least if the original plane of vibration was east and west. By some process, of which he gives no account, Foucault arrived at the result that the plane of oscillation must, in any latitude, appear to make a complete revolution in $24^h \times$ cosec latitude. This curious result has been amply verified by experiment.

The equations of motion of the pendulum, referred to rectangular axes fixed in direction in space and drawn from the earth's centre, the polar axis being that of $z$, are obviously

$$m\frac{d^2x}{dt^2} = -\mathrm{T}\frac{x-a}{l} + m\mathrm{X},$$

with similar expressions in $y$ and $z$ ($a$, $b$, $c$ being the coordinates of the point of suspension, T the tension, $l$ the length of the string, and X, Y, Z the components of gravity).

The equations of motion referred to a new set of axes parallel to the former, but drawn through the point of suspension, are

$$\left.\begin{aligned} m\frac{d^2(x-a)}{dt^2} &= -\mathrm{T}\frac{x-a}{l} + m\left(\mathrm{X} - \frac{d^2a}{dt^2}\right) \\ \&c. &= \&c. \end{aligned}\right\} \quad . \quad . \quad . \quad (1).$$

Let us now refer the motion to axes turning with the earth, but drawn from the point of suspension. If the axis of $\xi$ be drawn vertically, and the axes of $\eta$, $\zeta$ respectively southwards and eastwards; and if $\omega t$ be the angle at time $t$ between the planes of $xz$ and $\xi\eta$, $\lambda$ being the co-latitude of the point of suspension, we have (assuming that $\xi$ intersects $z$)

$$\begin{aligned} \cos x\xi &= \sin\lambda\cos\omega t, \\ \cos y\xi &= \sin\lambda\sin\omega t, \\ \cos z\xi &= \cos\lambda, \ \&c. \end{aligned}$$

By means of these expressions we can at once find the values of $x-a$, $y-b$, $z-c$ in terms of $\xi$, $\eta$, $\zeta$, $t$, as follows:

$$\begin{aligned} x-a &= \xi\sin\lambda\cos\omega t + \eta\cos\lambda\cos\omega t - \zeta\sin\omega t, \\ y-b &= \xi\sin\lambda\sin\omega t + \eta\cos\lambda\sin\omega t + \zeta\cos\omega t, \\ z-c &= \xi\cos\lambda \qquad\quad - \eta\sin\lambda. \end{aligned}$$

Let $\gamma$ be the acceleration due to the attraction of gravity alone, and $\nu$ the angle (nearly equal to $\lambda$) which its direction makes with the polar axis. [We have above in effect assumed that its direction lies in the plane of $z\xi$, as we have assumed that the axis of $\xi$ intersects the polar axis, while we know that the centrifugal force lies in their common plane.] Let $r$ be the distance of the point of suspension from the earth's centre, $\mu$ the angle its direction makes with the polar axis. Then

$$a = r\sin\mu\cos\omega t, \quad b = r\sin\mu\sin\omega t, \quad c = r\cos\mu.$$

With these data we transform equations (1) from $x$, $y$, $z$ to $\xi$, $\eta$, $\zeta$. The equations immediately obtained are inconveniently long for our columns. But they are easily simplified as follows.

We contemplate small vibrations only; so we may treat $\xi$ as being practically equal to $-l$, and omit its differential coefficients. We also omit powers and products of $\eta$, $\zeta$, and all terms in $\omega^2$, except those in which it is multiplied by a large quantity. For it is known that the centrifugal force at the equator is about 1/289th of gravity, or that approximately

$$r\omega^2 = g/289.$$

With these considerations, and the condition that to the degree of approximation desired we have $\mathrm{T} = mg$, we still further simplify our equations. We are led to recognize that $\gamma\cos\nu = g\cos\lambda$; and thus we have finally

$$\left.\begin{aligned} \frac{d^2\eta}{dt^2} - 2\omega\cos\lambda\frac{d\zeta}{dt} + \frac{g}{l}\eta &= 0 \\ \frac{d^2\zeta}{dt^2} + 2\omega\cos\lambda\frac{d\eta}{dt} + \frac{g}{l}\zeta &= 0 \end{aligned}\right\} \quad . \quad . \quad . \quad (2)$$

These are the equations of the motion of the bob, referred to horizontal plane fixed to the earth. The middle terms obviously depend upon the earth's rotation.

To interpret equations (2) it is convenient to employ a second change of coordinates—to refer the motion to axes revolving uniformly in the plane of $\eta$, $\zeta$, with angular velocity $\Omega$. If $\mathfrak{y}$, $\mathfrak{z}$ be the coordinates referred to the new axes, we have by analytical geometry

$$\eta = \mathfrak{y}\cos\Omega t - \mathfrak{z}\sin\Omega t, \quad \zeta = \mathfrak{y}\sin\Omega t + \mathfrak{z}\cos\Omega t,$$

the substitution of which in (2) leads to the equations

$$\frac{d^2\mathfrak{y}}{dt^2} + \frac{g\mathfrak{y}}{l} = 0, \qquad \frac{d^2\mathfrak{z}}{dt^2} + \frac{g\mathfrak{z}}{l} = 0 \quad . \quad . \quad . \quad . \quad . \quad (3),$$

provided we take

$$\Omega = -\omega\cos\lambda \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4),$$

and omit as before terms of the order $\omega^2$.

(4) shows that the new axes rotate, in the *opposite* direction to that of the earth, with the component of the earth's angular velocity about the vertical at the place. And, in the plane so revolving, we see by (3) that the bob of the pendulum describes an approximately elliptic orbit, of which a straight line is a particular case.

A *circular* path being obviously possible, let us assume as particular integrals of (2)

$$\eta = c\cos(pt+\alpha), \quad \zeta = c\sin(pt+\alpha).$$

The substitution of these values gives the same result

$$p^2 + 2\omega p\cos\lambda - g/l = 0$$

in each of equations (2).

Put $g/l = n^2$, then the values of $p$ are, to the degree of approximation above employed, $\pm n - \omega\cos\lambda$, so that the (apparent) angular velocity of a conical pendulum is increased or diminished by $\omega\cos\lambda$ according as its direction of rotation is negative or positive.

Varying constraint.

§ 159. The preceding problem is a particular case of the following general one. *To find the motion of a particle subjected to the action of given forces and under varying constraint.* It would lead us to details incompatible with our limits to enter upon a full discussion of so wide a question, but we give one or two simple and useful cases to show the commoner forms of procedure.

*A particle under any forces, and resting on a smooth horizontal plane, is attached by an inextensible string to a point which moves.*

*in a given manner in that plane; to determine the motion of the particle.*

Let $x, y, \bar{x}, \bar{y}$ be the coordinates, at time $t$, of the particle and point, $a$ the length of the string, R the tension of the string, and $m$ the mass of the particle.

For the motion of the particle we have

$$\left.\begin{aligned} m\frac{d^2x}{dt^2} &= mX - R\frac{x-\bar{x}}{a} \\ m\frac{d^2y}{dt^2} &= mY - R\frac{y-\bar{y}}{a} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (1),$$

with the condition $(x-\bar{x})^2+(y-\bar{y})^2=a^2$.

Now $\bar{x}, \bar{y}$ are given functions of $t$. Take from both sides of the equations (1) the quantities $m\frac{d^2\bar{x}}{dt^2}$, $m\frac{d^2\bar{y}}{dt^2}$, respectively, and we have the equations of *relative* motion

$$\left.\begin{aligned} m\frac{d^2(x-\bar{x})}{dt^2} &= mX - R\frac{x-\bar{x}}{a} - m\frac{d^2\bar{x}}{dt^2} \\ m\frac{d^2(y-\bar{y})}{dt^2} &= mY - R\frac{y-\bar{y}}{a} - m\frac{d^2\bar{y}}{dt^2} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (2).$$

These are precisely the equations we should have had if the point had been fixed, and in addition to the forces X, Y, and R acting on the particle, we had applied, reversed in direction, the accelerations of the point's motion with the mass as a factor. It is evident that the same theorem will hold in three dimensions. The accelerations $\frac{d^2\bar{x}}{dt^2}$, $\frac{d^2\bar{y}}{dt^2}$ are known as functions of $t$, and therefore the equations of relative motion are completely determined.

*Let there be no impressed forces, and suppose first that the point moves with constant velocity in a straight line.*

Here $\frac{d\bar{x}}{dt}$, $\frac{d\bar{y}}{dt}$ are constant, and therefore no terms are introduced in the equations of motion.

Again, *suppose the point's motion to be rectilinear, but uniformly accelerated.*

The relative motion will evidently be that of a simple pendulum from side to side of the point's line of motion. In certain cases, when the angular velocity exceeds a certain limit, we shall have the string occasionally untended; and this will give rise to an impact when it is again tended. While the string is untended the particle moves, of course, in a straight line.

*Suppose the point to move, with constant angular velocity $\omega$, in a circle whose radius is $r$ and centre origin.*

Here, supposing the point to start from the axis of $x$,

$$\bar{x}=r\cos\omega t, \quad \bar{y}=r\sin\omega t.$$

Hence the equations of motion are, since

$$\left.\begin{aligned} &\frac{d^2\bar{x}}{dt^2}=-\omega^2\bar{x}, \quad \frac{d^2\bar{y}}{dt^2}=-\omega^2\bar{y}, \\ &\frac{d^2(x-\bar{x})}{dt^2}=-R\frac{x-\bar{x}}{a}+\omega^2\bar{x}, \\ &\frac{d^2(y-\bar{y})}{dt^2}=-R\frac{y-\bar{y}}{a}+\omega^2\bar{y}, \\ &(x-\bar{x})^2+(y-\bar{y})^2=a^2. \end{aligned}\right\}$$

Whence

$$(x-\bar{x})\frac{d^2(y-\bar{y})}{dt^2}-(y-\bar{y})\frac{d^2(x-\bar{x})}{dt^2} = \omega^2\left\{(x-\bar{x})\bar{y}-(y-\bar{y})\bar{x}\right\};$$

or, in polar coordinates, for the relative motion,

$$\frac{d}{dt}\left(a^2\frac{d\theta}{dt}\right)=-\omega^2ar\sin(\theta-\omega t),$$

or

$$\frac{d^2(\theta-\omega t)}{dt^2}=-\omega^2\frac{r}{a}\sin(\theta-\omega t).$$

Now $\theta-\omega t$ is the inclination of the string to the radius passing through the point; call it $\phi$, and we have

$$\frac{d^2\phi}{dt^2}=-\omega^2\frac{r}{a}\sin\phi,$$

the equation of motion of a simple pendulum whose length is $\frac{g\alpha}{r\omega^2}$.

The particle therefore moves, with reference to the uniformly revolving radius of the circle described by the point, just as a simple pendulum with reference to the vertical.

*A particle moves in a smooth straight tube which revolves with constant angular velocity round a vertical axis to which it is perpendicular; to determine the motion.*

Here, referring the particle to polar coordinates in the plane of motion of the tube, we have $\theta=\text{constant}=\omega$, $P=0$ (§ 47), and thus for the acceleration along the tube

$$\ddot{r}-r\omega^2=0;$$

whence

$$r=Ae^{\omega t}+Be^{-\omega t}.$$

Suppose the motion to commence at time $t=0$ by the cutting of a string, length $a$, attaching the particle to the axis. The velocity of the particle at that instant along the tube is zero. Hence at $t=0$

$$r=a=A+B,$$

$$\dot{r}=0=A-B;$$

so that $A=B=\frac{1}{2}a$, and $r=\frac{1}{2}a(e^{\omega t}+e^{-\omega t})$.

In fig. 51 let OM be the initial position of the tube and A that of the particle, and let OL and Q be the tube and particle at time $t$. Then $OA=a$, arc $AP=a\omega t$, $OQ=r$, and we have

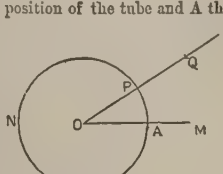

Fig. 51.

$$OQ=\tfrac{1}{2}OA\left(e^{\frac{\text{arc AP}}{OA}}+e^{-\frac{\text{arc AP}}{OA}}\right).$$

From this we see that OQ and the arc AP are corresponding values of the ordinate and abscissa of a catenary whose parameter is OA. Here the vertical pressure on the tube is equal to the weight of the particle, while the horizontal pressure is

$$-\frac{m}{r}\frac{d}{dt}(r^2\dot{\theta})=-2m\omega^2=-m\omega^2a(e^{\omega t}-e^{-\omega t}).$$

From this equation, combined with the value of $r$, we easily deduce for the horizontal pressure the value

$$2m\omega^2\sqrt{(r^2-a^2)},$$

and it is therefore proportional at any instant to the tangent drawn from Q to the circle APN.

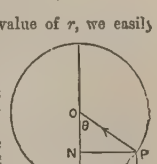

Fig. 52.

*Let the tube be in the form of a circle turning with constant angular velocity about a vertical diameter.* Let AO (fig. 52) be the axis, P the position of the particle at any time. Let $POA=\theta$ denote the particle's position, and R the pressure on the tube in the direction of OP.

We have

$$a\frac{d^2\cos\theta}{dt^2}=g-R\cos\theta,$$

$$a\frac{d^2\sin\theta}{dt^2}-\omega^2a\sin\theta=-R\sin\theta$$

Eliminating R,

$$a\frac{d^2\theta}{dt^2}-a\omega^2\sin\theta\cos\theta=-g\sin\theta \quad . \quad . \quad . \quad . \quad (1).$$

The position of equilibrium will therefore be given by

$$\sin\theta=0; \text{ or by } \theta=\gamma, \text{ where } \cos\gamma=\frac{g}{a\omega^2}.$$

Integrating (1),

$$\left(\frac{d\theta}{dt}\right)^2=C+2\omega^2\cos\gamma\cos\theta-\omega^2\cos^2\theta \quad . \quad . \quad . \quad (2).$$

Suppose the particle to pass through the lowest point with velocity $a\omega_1$, we have

$$\left(\frac{d\theta}{dt}\right)^2=\omega_1^2-2\omega^2\cos\gamma(1-\cos\theta)+\omega^2\sin^2\theta$$

$$=\omega^2\left\{(1-\cos\gamma)^2+\frac{\omega_1^2}{\omega^2}-(\cos\theta-\cos\gamma)^2\right\},$$

and $\frac{d\theta}{dt}$ can never vanish if $\frac{\omega_1^2}{\omega^2}>4\cos\gamma$, or $\omega_1^2>\frac{4g}{a}$, that is, if the velocity at the lowest point be greater than that due to the level of the highest point.

If $\omega_1^2<\frac{4g}{a}$, the particle will oscillate; and, if $\frac{d\theta}{dt}=0$, when $\theta=\alpha$, then

$$\left(\frac{d\theta}{dt}\right)^2=\frac{2g}{a}(\cos\theta-\cos\alpha)-\omega^2(\cos^2\theta-\cos^2\alpha),$$

$$=\omega^2(\cos\theta-\cos\alpha)\left(\frac{2g}{a\omega^2}-\cos\alpha-\cos\theta\right),$$

$$=\omega^2(\cos\theta-\cos\alpha)(2\cos\gamma-\cos\alpha-\cos\theta);$$

and therefore, if $2\cos\gamma-\cos\alpha>1$, the particle will oscillate through the lowest point.

If $1>2\cos\gamma-\cos\alpha>-1$, then, putting

$$2\cos\gamma-\cos\alpha=\cos\beta,$$

$$\left(\frac{d\theta}{dt}\right)^2=\omega^2(\cos\theta-\cos\alpha)(\cos\beta-\cos\theta),$$

and the particle will oscillate on one side of the vertical diameter.

In each of these three cases the complete solution of the problem can be exhibited in terms of elliptic functions. In the last two cases, when the arcs of oscillation are very small, a sufficient solution may easily be obtained by the usual methods of approximation. This is a particularly instructive example.

§ 160. As a final example of constrained motion of a particle, let us find the form of a curve such that a particle will slide down any arc of it, from the origin, in the same time as down the chord of that arc. If OA, OB (fig. 53) be any two chords, it is plain that the difference of the times down these chords must be equal to the time of describing the arc AB. But, if OA make an angle $\theta$ with the vertical, the time of descent along it is

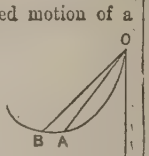

Fig. 53.

$$\sqrt{\frac{2\mathrm{OA}}{g\cos\theta}}.$$

And the velocity at A is $\sqrt{2g\mathrm{OA}\cos\theta}$, so that the time of describing AB (considered as infinitesimal) is

$$\mathrm{AB}/\sqrt{2g\mathrm{OA}\cos\theta}.$$

If we put $r$ for OA, our condition gives at once

$$\frac{d}{d\theta}\sqrt{\frac{2r}{g\cos\theta}}=\frac{ds}{d\theta}\Big/\sqrt{2gr\cos\theta},$$

where $s$ is the length of the arc OA. This equation is easily integrated, and the resulting relation is

$$r^2=a^2\sin 2\theta,$$

which belongs to the well-known lemniscate of Bernoulli. From its form we see that the vertical line from which $\theta$ is measured is a tangent at O; so that the motion in arc commences vertically

Disturbed motion.

§ 161. To complete this elementary sketch of the dynamics of a single particle we take an instauce or two of "disturbed motion." The essence of this question is usually that the disturbing forces are, at any instant, small in comparison with the forces producing the motion; so that, during any brief period, the motion is practically the same as if no disturbing cause had been at work. But, in time, the effects of the disturbance may become so great as entirely to change the dimensions and form of the orbit described. The mathematical method which has been devised to meet this question depends upon what has just been said. The *character* of the path is not, at any particular instant, affected by the disturbance; but its form and dimensions are. Hence, as the first depends upon the *form* of the equations which represent it, while the latter depend upon the actual and relative magnitudes of the constants involved, we settle, once for all, the *form* of the equation as if no disturbing cause had acted. But we are thus entitled to assume that the constants which it involves are quantities which vary with the time in consequence of the slight, but persistent, effects of the disturbance. And, as we know that, if at any moment the disturbance were to cease, the motion would forthwith go on for ever in the orbit *then being described*, we may assume that in the expressions for the components of the velocity no terms occur depending on the rate of alteration of the values of the constants. This, as will be seen below, very much simplifies the mathematical treatment of such questions.

Pendulum.

*Suppose a cycloidal pendulum, or a simple pendulum vibrating through very small arcs, to be subjected to a simple harmonic disturbance in the direction of its motion.* The equation of motion will obviously be of the form

$$\ddot\theta+n^2\theta=\mathrm{A}\cos mt,$$

where $n^2=l/g$, as in § 134.

The integral of this equation is

$$\theta=\mathrm{P}\cos(nt+\mathrm{Q})-\frac{\mathrm{A}}{m^2-n^2}\cos mt.$$

We see then that the result is the superposition of a new simple harmonic motion on the natural simple harmonic motion of the undisturbed bob, and that it is altogether independent of the amplitude and phase of the undisturbed motion. So long as the disturbance is very small, this new part of the motion may be neglected, unless $m$ is very nearly equal to $n$. For in that case the amplitude of the disturbance may become much greater than that of the original motion. When $m$ is equal to $n$, the integral changes its form, and we have

$$\theta=\mathrm{P}\cos(nt+\mathrm{Q})+\mathrm{A}\frac{t}{2n}\sin nt.$$

This shows that, in the special case of a disturbance of the same period as the undisturbed motion, the nature of the motion is entirely changed. Thus, suppose the pendulum to be at rest at its lowest point when the disturbance is applied; then we have merely

$$\theta=\mathrm{A}\frac{t}{2n}\sin nt,$$

a simple harmonic motion whose amplitude increases in proportion to the time elapsed since the disturbance commenced.

Point of suspension disturbed.

§ 162. As another illustration, *suppose the point of suspension of a simple pendulum to have a simple harmonic motion of small amplitude in a horizontal line.*

Here the equations of motion are (to horizontal and vertical axes)

$$m\ddot x=-\mathrm{T}\frac{x-\xi}{l},$$

$$m\ddot y=mg-\mathrm{T}\frac{y}{l}.$$

But if we suppose the oscillations to be small, we may write $x-\xi=l\theta$, $y=l$, where $l$ is the length of the pendulum, and $\theta$ the angle it makes with the vertical. Then we have

$$\ddot x=l\ddot\theta+\ddot\xi=l\ddot\theta+\mathrm{A}\cos mt, \text{ suppose, and } \ddot y=0.$$

Hence $$mg=\mathrm{T},$$

and $$l\ddot\theta+\mathrm{A}\cos mt=-g\theta,$$

which is precisely the equation of the preceding investigation.

Motion of a sling.

We see from this how to explain the somewhat puzzling phenomenon which we observe when we produce complete rotations of a stone in a sling by a comparatively trifling motion of the hand. All that is necessary is that the hand should have a slight to and fro horizontal motion, in a period nearly equal to that in which the sling and stone would vibrate as a pendulum. This result of particle kinetics is (like that in § 161) of great value in other branches of physics, especially sound, light, and radiant heat.

Disturbance generally.

To illustrate the general principle, let us take the case of one degree of freedom. Then the equation of motion of an unit mass must be of the form

$$\ddot\theta=\Theta+\Theta_1,$$

where $\Theta$ represents the normal force, and $\Theta_1$ the abnormal or disturbing force. Leaving out $\Theta_1$ for the moment, let the integral of $\ddot\theta=\Theta$ be

$$\theta=f(\alpha,\ \beta,\ t),$$

in which $\alpha$ and $\beta$ are two arbitrary constants. We may now suppose $\alpha$ and $\beta$ to be variable in such a way that the equation shall still be satisfied by this value of $\theta$ when the disturbing forces are included. This imposes only one condition on the two independent quantities $\alpha$ and $\beta$, so that to determine them completely we must impose a second. This we do, as already explained, by making the expression for the speed independent of the rates of alteration of $\alpha$ and $\beta$, and we gain the advantage that our solution will accord at every instant with what would be the actual future motion if the disturbance were suddenly to cease. The speed is

$$\dot\theta=f'(\alpha)\dot\alpha+f'(\beta)\dot\beta+f'(t).$$

We therefore assume

$$f'(\alpha)\dot\alpha+f'(\beta)\dot\beta=0.$$

Taking account of this and differentiating again, we have

$$\ddot\theta=\frac{d}{d\alpha}f'(t)\cdot\dot\alpha+\frac{d}{d\beta}f'(t)\cdot\dot\beta+f''(t).$$

Hence we have, for the determination of $\alpha$ and $\beta$, the equations

$$f'(\alpha)\frac{d\alpha}{dt}+f'(\beta)\frac{d\beta}{dt}=0,$$

$$\frac{d}{d\alpha}f'(t)\cdot\frac{d\alpha}{dt}+\frac{d}{d\beta}f'(t)\cdot\frac{d\beta}{dt}=\Theta_1.$$

These give the values of $\frac{d\alpha}{dt}$ and $\frac{d\beta}{dt}$, and so completely solve the problem.

Impulsive change of velocity.

§ 163. In a somewhat similar way we may treat the effects of a slight disturbance, made once for all, in the motion of a particle describing a definite path under given forces. A single example must suffice.

Thus, we have in an elliptic orbit about the focus, § 144 (9),

$$\frac{1}{2}v^2 = \frac{\mu}{r} - \frac{\mu}{2a}.$$

At the end of the major axis farthest from the focus this becomes

$$V^2 = \frac{\mu}{a}\,\frac{1-e}{1+e}.$$

Now if at this point V be made $V+\delta V$, without change of direction, we have the condition that in the new orbit $a(1+e)$ shall have the same value as in the old, since this will still be the apsidal distance.

Hence
$$\delta(V^2) = \delta\left(\frac{\mu}{a}\,\frac{1-e}{1+e}\right),$$

and
$$\delta\left\{a(1+e)\right\} = 0;$$

$$\therefore\ 2V\delta V = -\frac{\mu}{a}\,\frac{\delta e}{1+e},$$

or
$$\delta e = -2\sqrt{\left\{\frac{a}{\mu}(1-e^2)\right\}}\,\delta V,$$

and
$$\delta a = -\frac{a}{1+e}\delta e,$$

$$= 2\sqrt{\left(\frac{a^3}{\mu}\,\frac{1-e}{1+e}\right)}\delta V,$$

which determine the increase of the major axis and the diminution of the excentricity; and the same method is applicable to more complicated cases.

A very excellent series of examples of the elementary geometrical treatment of disturbed orbits is to be found in Airy's *Gravitation*.

### *Third Law. Kinetics of Two or More Particles.*

Stress between particles.

§ 164. We have, by means of the first two laws, arrived at a *definition* and a *measure* of force, and have found how to compound, and therefore how to resolve, forces, and also how to investigate the conditions of equilibrium or motion of a single particle subjected to given forces. But more is required before we can completely understand the more complex cases of motion, especially those in which we have mutual actions between or amongst two or more bodies,—such as, for instance, tensions or pressures or transference of energy in any form. This is perfectly supplied by the third law, on which Newton comments nearly as follows.

Newton's comments on third law.

§ 165. If one body presses or draws another, it is pressed or drawn by this other with an equal force in the opposite direction. If any one presses a stone with his finger, his finger is pressed with an equal force in the opposite direction by the stone. A horse, towing a boat on a canal, is dragged backwards by a force equal to that which he impresses on the towing-rope forwards. By whatever amount, and in whatever direction, one body has its "motion" changed by impact upon another, this other body has its "motion" changed by the same amount in the opposite direction; for at each instant during the impact they exerted on each other equal and opposite pressures. When neither of the two bodies has any rotation, whether before or after impact, the changes of velocity which they experience are inversely as their masses. When one body attracts another from a distance, this other attracts it with an equal and opposite force.

Stress.

§ 166. We shall for the present take for granted that the mutual action between two particles may in every case be imagined as composed of equal and opposite forces in the straight line joining them, two such equal and opposite forces constituting a "stress" between the particles. From this it follows that the sum of the quantities of motion, parallel to any fixed direction, of the particles of any system influencing one another in any possible way, remains unchanged by their mutual action; also that the sum of the moments of momentum of all the particles round any line in a fixed direction in space, and passing through any point moving uniformly in a straight line in any direction, remains constant. From the first of these propositions we infer that the centre of mass of any system of mutually influencing particles, if in motion, continues moving uniformly in a straight line, except in so far as the direction or speed of its motion is changed by stresses between the particles and some other matter not belonging to the system; also that the centre of mass of any system of particles moves just as all their matter, if concentrated in a point, would move under the influence of forces equal and parallel to the forces really acting on its different parts. From the second we infer that the axis of resultant rotation through the centre of mass of any system of particles, or through any point either at rest or moving uniformly in a straight line, remains unchanged in direction, and the sum of moments of momentum round it remains constant, if the system experiences no force from without, or only forces whose resultant passes through the centre of inertia of the system. This principle is sometimes called "conservation of areas," a very misleading designation.

Conservation of momentum, and of moment of momentum.

§ 167. Newton's scholium, which we treat as a fourth law, points out that resistances against acceleration are to be reckoned as reactions equal and opposite to the actions by which the acceleration is produced. Thus, if we consider any one material point of a system, its reaction against acceleration must be equal and opposite to the resultant of the forces which that point experiences, whether by the actions of other parts of the system upon it, or by the influence of matter not belonging to the system. In other words, it must be in equilibrium with these forces. Hence Newton's view amounts to this, that all the forces of the system, with the reactions against acceleration of the material points composing it, form groups of equilibrating systems for these points considered individually. Hence, by the principle of superposition of forces in equilibrium, all the forces acting on points of the system form, with the reactions against acceleration, an equilibrating set of forces on the whole system. This is the celebrated principle first explicitly stated and very usefully applied by D'Alembert in 1742, and still known by his name.

Consequences of Newton's scholium.

D'Alembert's principle.

Abstract theory of energy.

§ 168. Thus Newton lays, in an admirably distinct and compact manner, the foundations of the abstract theory of "energy," which recent experimental discovery has raised to the position of the grandest of known physical laws. He points out, however, only its application to mechanics. The *actio agentis*, as he defines it, which is evidently equivalent to the product of the effective component of the force into the velocity of the point at which it acts, is simply, in modern English phraseology, the rate at which the agent works, called the "power" of the agent. The subject for measurement here is precisely the same as that for which Watt, a hundred years later, introduced the practical unit of a "horse-power," or the rate at which an agent works when overcoming 33,000 times the weight of a pound through the distance of a foot in a minute,—that is, producing 550 foot-pounds of work per second. The unit, however, which is most generally convenient is that which Newton's definition implies, namely, the rate of doing work in which the unit of work or energy is produced in the unit of time.

Horse-power.

§ 169. Looking at Newton's words in this light, we see that they may be converted into the following:—

"Work done on any system of bodies (in Newton's

Newton's scholium.

statement, the parts of any machine) has its equivalent in work done against friction, molecular forces, or gravity, if there be no acceleration; but if there be acceleration, part of the work is expended in overcoming the resistance to acceleration, and the additional kinetic energy developed is equivalent to the work so spent."

When part of the work is done against molecular forces, as in bending a spring, or against gravity, as in raising a weight, the recoil of the spring and the fall of the weight are capable, at any future time, of reproducing the work originally expended. But in Newton's day, and long afterwards, it was supposed that work was absolutely lost by friction.

§ 170. If a system of bodies, given either at rest or in motion, be influenced by no forces from without, the sum of the kinetic energies of all its parts is augmented in any time by an amount equal to the whole work done in that time by the stresses which we may imagine as taking place between its points. When the lines in which these stresses act remain all unchanged in length, the sum of the kinetic energies of the whole system remains constant. If, on the other hand, one of these lines varies in length during the motion, the stress in that line will do work or will consume work, according as the distance varies with or against it.

Conservative system.

§ 171. Experiment has shown that the mutual actions between the parts of any system of natural bodies always perform, or always consume, the same amount of work during any motion whatever, by which the system can pass from one particular configuration to another; so that each configuration corresponds to a definite amount of kinetic energy. Hence no arrangement is possible in which a gain of kinetic energy can be obtained when the system is restored to its initial configuration. In other words, "the perpetual motion" is impossible.

Potential energy.

The "potential energy" (§ 113) of such a system, in the configuration which it has at any instant, is the amount of work that its mutual forces perform during the passage of the system from any one chosen configuration to the configuration at the time referred to. It is generally convenient so to fix the particular configuration chosen for the zero of reckoning of potential energy that the potential energy in every other configuration practically considered shall be positive.

As particular instances of this we may notice many of the results already given: for instance, the ordinary expression for the velocity acquired by a falling stone (§ 28), $\frac{1}{2}v^2 = gx$; for here $\frac{1}{2}mv^2$ is the kinetic energy acquired, while $mg.x$ is the work done by the weight $(mg)$ during the fall. Similarly, we have in the motion of a planet, the expression $v^2 = \mu\left(\frac{2}{r} - \frac{1}{a}\right)$, which leads to $m\frac{v^2 - v_1^2}{2} = \frac{m\mu}{rr_1}(r_1 - r)$. Here $\frac{m\mu}{rr_1}$ is the "mean value" of the force for distances from $r$ to $r_1$, and therefore the right-hand side is the work done by the force, while the left-hand side is the increase of kinetic energy produced.

To put this in an analytical form, we have merely to notice that, by what has just been said, the value of

$$\Sigma\int\left(X\frac{dx}{ds} + Y\frac{dy}{ds} + Z\frac{dz}{ds}\right)ds$$

is independent of the paths pursued from the initial to the final positions, and therefore that

$$\Sigma(Xdx + Ydy + Zdz)$$

is a complete differential. If, in accordance with what has just been said, this be called $-dV$, V is the potential energy, and

$$X_1 = -\frac{dV}{dx_1}, \quad \ldots$$

Also, by the second law of motion, if $m_1$ be the mass of a particle of the system whose coordinates are $x_1, y_1, z_1$ we have

$$m_1\frac{d^2x_1}{dt^2} = X_1, \text{ \&c. = \&c.}$$

and

$$\Sigma\left\{m\left(\frac{dx}{dt}\frac{d^2x}{dt^2} + \frac{dy}{dt}\frac{d^2y}{dt^2} + \frac{dz}{dt}\frac{d^2z}{dt^2}\right)\right\}dt = \Sigma(Xdx + Ydy + Zdz) = -dV.$$

Conservation of energy.

The integral is

$$\tfrac{1}{2}\Sigma(mv^2) + V = H,$$

that is, *the sum of the kinetic and potential energies is constant.* This is called the "*conservation of energy.*"

In abstract dynamics, with which alone this article is concerned, there is loss of energy by friction, impact, &c. This we simply leave as loss, to be accounted for by Thermodynamics.

Frictional dissipation.

§ 172. Hitherto, as we have been dealing with the motion of a single particle only, we have not required the assistance of even the third law. For, in those cases, already treated, in which one of the forces was not given, it was at all events due to a given constraint, and the geometrical circumstances of the constraint supplied the means of determining it. In fact we were not, in any case, concerned with reaction; or, to use the more modern form of expression, we were engaged with one half, only, of a stress. When a stone's motion was investigated, no account was taken of the stone's attraction for the earth; when we dealt with central forces, the centre was supposed to be fixed; and, even in the cases in which variable constraint was supposed, the curve which produced it was assumed to move in a manner absolutely determined beforehand, and in no way affected by the reaction of the mass acted upon.

Other side of stress.

But, in nature, circumstances are not so simple. Though, for all practical purposes, we may calculate the motion of an ordinary projectile as if its attraction had no influence upon the motion of the earth, we cannot do so in the case of the motion of the moon about the earth. The mass of the moon is about $\frac{1}{80}$th of that of the earth, and its gravitation effects on the motion of the earth cannot be neglected. The moon, in fact, moves faster round the earth than would a projectile of less mass, though moving in precisely the same relative orbit (§ 146). If the earth's motion were not accelerated by the reaction of the moon, the sole crest of the lunar tide-wave would be on the side of the earth next the moon, and there would be full-tide once only in a single rotation of the earth about its axis. We need not give further instances here; they will present themselves in almost every case we investigate.

Examples of third law.

§ 173. To give a general notion of the applications of, and necessity for, the third law, we choose a few special cases, selected so as to give, in short compass, a sufficiently general glance at the whole subject.

Atwood's machine.

We take, first, the case of two stones or bullets connected by an inextensible string passing over a smooth pulley. Let their masses be $m$ and $m'$. Our physical condition is that the tension of the string, whatever be its value, is the same throughout; and this is accompanied by the geometrical condition that the length of the string is constant, or that the speeds of the two masses are equal but in opposite directions. Hence the amounts of increase of momentum in a given time are as the masses. But they are also as the forces, by the second law. Thus

$$m : m' :: T - mg : m'g - T.$$

This gives, at once,

$$T = \frac{2mm'}{m+m'}g;$$

so that the whole downward force on $m'$ is

$$m'g - T = m'\frac{m' - m}{m' + m}g,$$

and the whole upward force on $m$ is

$$T - mg = m\frac{m' - m}{m' + m}g.$$

The motion of the system is therefore of precisely the same

character as that of a free mass falling in a vertical line, but the acceleration is less, in the ratio of the difference of the two masses to their sum.

§ 174. This is the essence of the arrangement called *Atwood's Machine*, which used to be employed for the demonstration (in a rough way) of the first and second laws of motion, in certain simple cases. The main feature of the method is the artificial reduction of the acceleration, so that the motion of the falling body is rendered slow enough to be followed by the eye with some degree of accuracy. To prove the first law, a bar of metal was laid across one of two equal masses suspended as in the example; and the system was allowed to move under acceleration until the preponderating mass passed through a ring which arrested the bar. The subsequent motion, with no acceleration, was then observed by noting the passage of the falling mass in front of a vertical scale, while the observer also listened to the ticking of a pendulum escapement. For the verification of the second law, so far as uniform force is concerned, the apparatus was adjusted by trial so that the extra load was detached from the preponderating mass after 1, 2, 3, &c., beats of the pendulum; and the subsequent uniform speed was found to be nearly in proportion to these numbers. And, again, to prove that momentum acquired is, *cæteris paribus*, proportional to the force, the effects of bars of different masses were compared by the same process.

If $x$ and $l-x$ be the portions of the string on opposite sides of the pulley at time $t$, we have

$$m\frac{d^2x}{dt^2} = mg - \mathrm{T} = m\ddot{x},$$

$$m'\frac{d^2}{dt^2}(l-x) = m'g - \mathrm{T} = -m'\ddot{x}.$$

Hence by elimination of T we have

$$\frac{m-m'}{m+m'}g = \ddot{x},$$

and by elimination of $\ddot{x}$

$$\mathrm{T} = \frac{2mm'}{m+m'}g, \text{ as before.}$$

When one of the masses is vibrating pendulum-wise, the problem assumes a very much more difficult aspect. We will take it later as an example of the application of Lagrange's general method.

Chain-shot.

§ 175. Let us now suppose these masses, so connected, to be thrown like a chain-shot. We see by § 166 that their centre of inertia moves as if the masses were concentrated there. Also that the moment of momentum is unaffected. Hence we have only to find the initial position and motion of the centre of inertia, and the plane and amount of the initial moment of momentum; and the complete determination of the motion follows. This case is precisely the same as that of a well-thrown quoit, the rotation of which is about its axis of symmetry. It is, so far as § 166 goes, the case of an ill-thrown quoit, which appears to wabble about in an irregular manner. But these are matters properly to be treated under Kinetics of a Rigid System.

Masses connected by elastic string.

§ 176. Suppose, next, two masses $m_1$ and $m_2$ to be connected together by an elastic string, the extension of the string being proportional to the tension. Let $m_1$ be held in the hand, while $m_2$ hangs at rest. Then let the system be allowed to fall. What is the nature of the motion? Without mathematical investigation it is easy to see that, the moment the masses are left free to fall, the tension of the stretched string will gradually draw them together. When it has thus contracted to its normal length, $l$, the *relative* speed of the two masses will have a definite value. This will continue to be the relative speed until they have passed one another and again arrived at a mutual distance $l$. At that instant the tension of the string comes into play again; the relative speed becomes less and less, finally vanishing when the distance between the masses is what it was at starting. Then the relative speed becomes again one of approach, increasing steadily till the distance between the masses is $l$. This maximum speed of approach continues till, after again passing one another, the particles once more reach the relative distance $l$. And so on. All this time, however, their common centre of inertia has been steadily falling with uniformly accelerated speed, as if the masses had been concentrated at it into one. Since $l$ is the unstretched length of the string, if we call E its modulus of elasticity, its tension at any other length, $\lambda$, is

$$\mathrm{T} = \mathrm{E}\frac{\lambda - l}{l}$$

by Hooke's law. Hence, if initially $m_1$ were at the origin, and the axis of $x$ be taken vertically downwards, we have for the initial coordinate of $m_2$

$$(x_2)_0 = -\left(\frac{m_2 g}{\mathrm{E}} + 1\right)l.$$

When the masses are moving, the third law informs us that the tension of the string acts equally and in opposite directions on them. Thus the equations of motion are

$$m_1\ddot{x}_1 = m_1 g + \mathrm{T},$$
$$m_2\ddot{x}_2 = m_2 g - \mathrm{T}.$$

By eliminating T we have at once

$$m_1\ddot{x}_1 + m_2\ddot{x}_2 = (m_1+m_2)g.$$

But

$$m_1x_1 + m_2x_2 = (m_1+m_2)\xi,$$

if $\xi$ be the coordinate of the centre of inertia of the two masses. Hence

$$\ddot{\xi} = g,$$

the ordinary equation for the fall of a stone. Thus

$$m_1x_1 + m_2x_2 = \mathrm{A} + \mathrm{B}t + \tfrac{1}{2}(m_1+m_2)gt^2.$$

Since $x_1 = 0$, $\dot{x}_1 = 0$, $x_2 = -\left(\frac{m_2 g}{\mathrm{E}} + 1\right)l$, $\dot{x}_2 = 0$, when $t = 0$, we have

$$\mathrm{A} = m_2\left(\frac{m_2 g}{\mathrm{E}} + 1\right)l, \quad \mathrm{B} = 0,$$

and thus

$$m_1x_1 + m_2x_2 = m_2\left(\frac{m_2 g}{\mathrm{E}} + 1\right)l + \tfrac{1}{2}(m_1+m_2)gt^2.$$

So long as $x_2 - x_1 > l$ we have also

$$\mathrm{T} = \mathrm{E}\left(\frac{x_2 - x_1}{l} - 1\right).$$

Hence, multiplying the first of the equations of motion by $m_2$, and the second by $m_1$, and taking the difference, we have

$$m_1m_2(\ddot{x}_2 - \ddot{x}_1) = -(m_1+m_2)\mathrm{E}\left(\frac{x_2 - x_1}{l} - 1\right).$$

The integral is

$$x_2 - x_1 = l + \mathrm{P}\cos(nt + \mathrm{Q}),$$

where

$$n^2 = \frac{m_1+m_2}{lm_1m_2}\mathrm{E}.$$

Also, by the data at starting, we have

$$\mathrm{Q} = 0, \quad \mathrm{P} = \frac{m_2 gl}{\mathrm{E}}.$$

Hence, finally,

$$x_1 = \frac{1}{m_1+m_2}\left(m_2\left(\frac{m_2 g}{\mathrm{E}} + 1\right)l + \tfrac{1}{2}(m_1+m_2)gt^2 - m_2l - \frac{m_2^2 gl}{\mathrm{E}}\cos nt\right).$$

$$= \tfrac{1}{2}gt^2 + \frac{m_2^2 gl}{\mathrm{E}(m_1+m_2)}(1 - \cos nt),$$

whence the value of $x_1$ can easily be found.

As soon as we have $nt > \frac{1}{2}\pi$ these values cease to represent the coordinates of the two masses, because they are deduced from equations involving constraint which, in the case supposed, has ceased for a time.

At the instant $nt = \frac{1}{2}\pi$ the relative speed of the masses is

$$-\frac{m_2 gl}{\mathrm{E}}\sqrt{\frac{(m_1+m_2)\mathrm{E}}{m_1m_2l}},$$

and their distance $l$.

This distance diminishes thenceforward with the above speed until the uppermost stone, having passed the lower one, falls below it to a distance $l$. We must, in order to trace the next part of the motion, reapply the differential equations above,—integrating them, and determining the

constants by the new conditions. This we leave to the reader.

Complex pendulum.

§ 177. Next let us take the case of a *Complex Pendulum*,—the motion of two or more pellets attached, at different points, to the same thread, supported at one end. The general solution of this question presents considerable difficulties, but if we confine our attention to slight disturbances it is easily treated by very elementary processes. In fact, just as a simple pendulum, *slightly* disturbed in a vertical plane, has simple harmonic motion which may be regarded as the resolved part of conical pendulum motion, so we may treat of a complex conical pendulum, and resolve its motions parallel to any vertical plane.

If there be but two masses attached to the string, it is clear that they must, if the motion is to be a persistent conical one, be always in one vertical plane with the point of suspension. And there are obviously *two* dispositions of the string which are consistent with kinetic stability.

Let A (fig. 54) be the point of suspension, then the masses may rotate steadily in either of the two configurations sketched. To keep either mass moving in a horizontal circle, all that is required is that the resultant force on it shall be horizontal, directed towards the centre, and producing an acceleration equal to $V^2/R$, as in § 34. Let the whole system turn with angular velocity $\omega$, and let the lengths of the strings be $a$ and $b$, their directions making angles $\theta$, $\phi$ with the vertical.

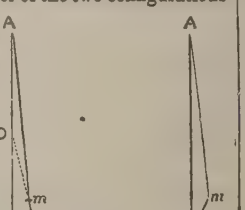

Fig. 54.

We will treat only the case in which these angles are so small that the arcs may be written in place of their sines. Then $m$ requires a horizontal resultant force $ma\theta\omega^2$ directed towards the axis, and M requires $M(a\theta+b\phi)\omega^2$ similarly directed. Also, as the strings are both very nearly vertical, the tension of the lower string may be taken as the weight of M, and that of the upper as the sum of the weights of M and $m$. Treating it, then, as a statical problem, we have for the mass $m$

$$ma\theta\omega^2=(M+m)g\theta-Mg\phi;$$

and for M

$$M(a\theta+b\phi)\omega^2=+Mg\phi.$$

These formulæ correspond to the first configuration, but a change of sign of $\phi$ adapts them to the second.

These two equations involve three unknown quantities $\omega^2$, $\theta$, $\phi$. But the *ratio*, only, of $\theta$ and $\phi$ is involved, so that two equations are sufficient. [We have confined ourselves to small values of $\theta$ and $\phi$, but have not assigned any limit to their smallness; so that their ratio has still an infinite range of values.]

Eliminate the ratio $\phi/\theta$ between the two equations; and we have, putting $\psi$ for $g/\omega^2$,

$$Ma\psi=(\psi-b)(M+m)\psi-ma),$$

or

$$(\psi-a)(\psi-b)=\frac{M}{M+m}ab.$$

It is clear that, because the right-hand member is essentially less than $ab$, there are always two real values of $\psi$, both positive, but one greater than the greater of $a$, $b$, the other less than the lesser. These correspond to two values of $\phi/\theta$, one positive, the other negative.

§ 178. The most general motion, then, of the double complex pendulum, when it vibrates in one plane, consists (for each of the masses) of the resultant of two simple harmonic motions, whose periods are

$$2\pi/\omega=2\pi\sqrt{\psi}/g,$$

$\psi$ having one or other of the two positive values given by the equation above, and being therefore the length of the equivalent simple pendulum. Thus the double complex pendulum supplies at once the mechanical means of tracing (by ink, sand, electric sparks, &c., § 156) a graphical representation of the composition of two simple harmonic motions, of different periods, in one line.

Analytically thus. For *any* displacement in one plane we have, $\theta$ and $\phi$ being, as before, the deflexions and T, T′ the tensions of the strings,

$$ma\left(\frac{d}{dt}\right)^2\sin\theta=-T\sin\theta+T'\sin\phi,$$

$$ma\left(\frac{d}{dt}\right)^2\cos\theta=mg-T\cos\theta+T'\cos\phi,$$

$$M\left(\frac{d}{dt}\right)^2(a\sin\theta+b\sin\phi)=-T'\sin\phi$$

$$M\left(\frac{d}{dt}\right)^2(a\cos\theta+b\cos\phi)=Mg-T'\cos\phi,$$

four equations to determine $\theta$, $\phi$, T, and T′. They become much more manageable if we assume that $\theta$ and $\phi$ are so small that their squares may be neglected. For then we have $\sin\theta=\theta$, $\cos\theta=1$, &c., and the equations become

$$ma\ddot{\theta}=-T\theta+T'\phi, \qquad 0=mg-T+T',$$

$$M(a\ddot{\theta}+b\ddot{\phi})=-T'\phi, \qquad 0=Mg-T'.$$

Thus $T'=Mg$, $T=(M+m)g$,

and we have $ma\ddot{\theta}=-(M+m)g\theta+Mg\phi$,

$$a\ddot{\theta}+b\ddot{\phi}=-g\phi.$$

Introducing an arbitrary multiplier $\lambda$, we have

$$\left(\frac{d}{dt}\right)^2\left\{(m+\lambda)a\theta+\lambda b\phi\right\}=-g\left\{(M+m)\theta+(\lambda-M)\phi\right\}$$

If we choose $\lambda$ so that

$$\frac{\lambda b}{(m+\lambda)a}=\frac{\lambda-M}{M+m}=e, \quad \ldots\ldots \quad (1),$$

the equation can be put in the form

$$\left(\frac{d}{dt}\right)^2(\theta+e\phi)=-\frac{g(M+m)}{(m+\lambda)a}(\theta+e\phi).$$

Now (1) is a quadratic equation in $\lambda$, and has obviously real roots, a positive root greater than M, and a negative root numerically less than $m$. Write (1) as the equation of an hyperbola, in the form

$$\mu=\frac{\lambda b}{(m+\lambda)a}-\frac{\lambda-M}{M+m},$$

and we see that $\lambda+m=0$ is an asymptote. The branch on the positive side of this asymptote lies mainly below the axis of $\lambda$. But $\mu$ is positive for $\lambda=M$, and also for $\lambda=0$.

Hence $\mu$ must pass through the value zero while $\lambda$ is greater than M, and for another value of $\lambda$ between zero and $-m$. But it is obvious that, for each of these values of $\lambda$, $m+\lambda$ is positive. Hence the equation may be written

$$\left(\frac{d}{dt}\right)^2(\theta+e\phi)=-n^2(\theta+e\phi),$$

where $e$ and $n$ have two sets of real values given as above; and thus we have the complete solution, with the four requisite arbitrary constants, in the form

$$\theta+e_1\phi=P_1\cos(n_1t+Q_1),$$

$$\theta+e_2\phi=P_2\cos(n_2t+Q_2).$$

This applies to every possible set of values of $a$, $b$, $m$, M; for, as we have seen, the two values of $\lambda$ are essentially different, at least *so long as neither of the masses becomes zero*. Thus, in this particular case, we are not met by the difficulty of equal roots. But it is very interesting to contrast this case, when $m$ is much greater than M, and $a=b$, with the case discussed in § 162 where the point of suspension of a simple pendulum has a horizontal simple harmonic motion of the period of the pendulum and in the vertical plane in which it vibrates. There the oscillations increase indefinitely; here they are in all cases essentially finite, in accordance with the assumptions made. There is, in fact, no increase of the energy of the system.

A very slight modification of the process gives us the result of small displacements not in one plane.

### *Kinetics of a System of Free Particles.*

§ 179. A system of free particles is subject only to their mutual attractions; to investigate the motion of the system.

System of free particles.

Let, at time $t$, $x_1$, $y_1$, $z_1$ be the coordinates of the particle whose mass is $m_1$, and let $\phi'(D)$ be the law of attraction. Let ${}_pr_q$ express the distance between the particles $m_p$ and $m_q$; then we have, for the motion of $m_1$,

$$m_1\frac{d^2x_1}{dt^2}=\Sigma\left\{m_1m_n\phi'({}_1r_n)\frac{x_n-x_1}{{}_1r_n}\right\} \quad . \quad . \quad . \quad . \quad (1),$$

$$m_1\frac{d^2y_1}{dt^2}=\Sigma\left\{m_1m_n\phi'({}_1r_n)\frac{y_n-y_1}{{}_1r_n}\right\} \quad . \quad . \quad . \quad . \quad (2),$$

$$m_1\frac{d^2z_1}{dt^2}=\Sigma\left\{m_1m_n\phi'({}_1r_n)\frac{z_n-z_1}{{}_1r_n}\right\} \quad . \quad . \quad . \quad . \quad (3),$$

with similar equations for each of the others, the summations being taken throughout the system. Before we can make any attempt at a solution of these equations, we must know their number, and the laws of attraction between the several pairs of particles. But some general theorems, independent of these data, may easily be obtained.

Conservation of momentum.

First, we have *Conservation of Momentum*. In the expression for $m_p\frac{d^2x_p}{dt^2}$, we have a term $m_pm_q\phi'({}_pr_q)\frac{x_q-x_p}{{}_pr_q}$,

and in $m_q\frac{d^2x_q}{dt^2}$ we have $m_qm_p\phi'({}_qr_p)\frac{x_p-x_q}{{}_qr_p}$.

Hence, if we add all the equations of the form (1) together, the result will be

$$m_1\frac{d^2x_1}{dt^2}+m_2\frac{d^2x_2}{dt^2}+\ldots\ldots=0;$$

or

$$\Sigma\left(m\frac{d^2x}{dt^2}\right)=\frac{d^2x}{dt^2}\Sigma(m)=0.$$

Similarly

$$\frac{d^2y}{dt^2}\Sigma(m)=0, \text{ and } \frac{d^2z}{dt^2}\Sigma(m)=0,$$

where (§ 109) $x$, $y$, $z$ is the centre of inertia of the system.

These equations show that the speed of the centre of inertia parallel to each of the coordinate axes remains invariable during the motion; that is, that *the centre of inertia of the system remains at rest, or moves with constant speed in a straight line.*

of moment of momentum.

Next we have *Conservation of Moment of Momentum*. For if we multiply in succession equation (1) by $y_1$, and equation (2) by $x_1$, and subtract, and take the sum of all such remainders through the system of equations of the forms (1) and (2), we have

$$\Sigma[m(xj-y\dot{x})]=0.$$

Integrating once, we have

$$\Sigma[m(x\dot{y}-y\dot{x})]=2A_3,$$

where the left-hand member is the moment of momentum of the system about the axis of $z$.

This equation shows (since $xy$ is any plane) that generally in the motion of a free system of particles, subject only to their mutual attractions, *the moment of momentum about every axis remains constant.*

of energy.

Finally, we have *Conservation of Energy*. Multiply (1) by $\frac{dx_1}{dt}$, (2) by $\frac{dy_1}{dt}$, (3) by $\frac{dz_1}{dt}$; and, treating similarly all the other equations, add them all together.

Let us consider the result as regards the term on the right-hand side involving the product $m_pm_q$.

Written at length it is

$$\frac{m_pm_q\phi'({}_pr_q)}{{}_pr_q}\left\{(x_q-x_p)\frac{dx_p}{dt}+(x_p-x_q)\frac{dx_q}{dt}\right.$$
$$\left.+\text{similar terms in } y \text{ and } z\right\};$$

and the portion in brackets is equal to

$$-\left\{(x_q-x_p)\frac{d}{dt}(x_q-x_p)+\text{similar terms in } y, z\right\}$$

or

$$-{}_pr_q\frac{d}{dt}({}_pr_q);$$

hence

$$\Sigma\left\{m\left(\frac{dx}{dt}\frac{d^2x}{dt^2}+\frac{dy}{dt}\frac{d^2y}{dt^2}+\frac{dz}{dt}\frac{d^2z}{dt^2}\right)\right\}$$
$$+\Sigma\left\{m_pm_q\phi'({}_pr_q)\frac{d}{dt}({}_pr_q)\right\}=0;$$

therefore, on integration,

$$\tfrac{1}{2}\Sigma(mv^2)+\Sigma\{m_pm_q\phi({}_pr_q)\}=H.$$

We see therefore that *the change in the kinetic energy of the system in any time depends only on the relative distances of the particles at the beginning and end of that time.*

Virial.

Another general expression for the kinetic energy of a system of particles, in terms of a function of the mutual forces, and the constraining forces if there be such, is readily found as follows.

If $x$, $y$, $z$ be the coordinates, at time $t$, of the particle $m$, we have

$$\left(\frac{d}{dt}\right)^2\Sigma m(x^2+y^2+z^2)=2\Sigma m(\dot{x}^2+\dot{y}^2+\dot{z}^2)+2\Sigma m(x\ddot{x}+y\ddot{y}+z\ddot{z}).$$

But if X, Y, Z be the components of the forces (of whatever kind) acting on $m$, we have (§ 119)

$$m\ddot{x}=X,\ m\ddot{y}=Y,\ m\ddot{z}=Z.$$

Thus

$$\left(\frac{d}{dt}\right)^2\Sigma m(x^2+y^2+z^2)=2\Sigma m(\dot{x}^2+\dot{y}^2+\dot{z}^2)+2\Sigma(Xx+Yy+Zz).$$

This expression was originally devised by Clausius for application to the kinetic theory of gases. The quantity $\Sigma m(x^2+y^2+z^2)$ is obviously half the sum of the three principal moments of inertia of the group of particles about the origin (§ 234).

In all cases of motion of a group, in which this sum is either constant or oscillates in an extremely short period about a constant value, the left-hand side may be regarded as (on the average at least) a vanishing quantity. Thus an equivalent of the kinetic energy is expressible as

$$-\tfrac{1}{2}\Sigma(Xx+Yy+Zz).$$

This expression is called the "virial."

In so far as it arises from the mutual action between two particles $m_p$ and $m_q$, its value is (in the notation above)

$$-\tfrac{1}{2}\left(m_pm_q\phi'({}_pr_q)\frac{x_q-x_p}{{}_pr_q}x_p+m_qm_p\phi'({}_pr_q)\frac{x_p-x_q}{{}_pr_q}x_q\right),$$

with corresponding terms in $y$ and $z$, altogether

$$=\tfrac{1}{2}m_pm_q\phi'({}_pr_q){}_pr_q.$$

Hence if we write, generally, $r$ for the distance between two of the particles, and R for the stress between them as depending on their mutual action, the corresponding part of the virial is

$$\tfrac{1}{2}\Sigma(Rr).$$

This is positive when the stresses are of the nature of tension.

When the mutual action is due to gravity only,

$$\phi'({}_pr_q)=\frac{1}{{}_pr_q^2},$$

and the part of the virial corresponding to this is

$$\tfrac{1}{2}m_pm_q/{}_pr_q,$$

expressing half the exhaustion of the potential energy of the system.

Virial of a gas in a vessel.

When the particles are in very great numbers, and enclosed in a vessel from the sides of which they rebound—as is supposed in the kinetic gas theory—the pressure $p$, per unit of surface, on the walls contained of the vessel must be taken into account. If $l$, $m$, $n$ be the direction cosines of the normal to the element $dS$ of the wall of the vessel, vessel whose coordinates are $x$, $y$, $z$, the corresponding part of the virial is

$$\tfrac{1}{2}p\iint dS(lx+my+nz)$$

extended over the whole internal surface. We here assume that $p$ is constant. But $lx+my+nz$ is the perpendicular from the origin on the plane of $dS$, so that the integral expresses three times the volume V of the vessel. Hence this part of the virial is

$$\tfrac{3}{2}pV.$$

Thus, in the case of a gas not acted on by external forces, the kinetic energy is

$$\tfrac{3}{2}pV+\tfrac{1}{2}\Sigma(Rr).$$

### *Impact of Smooth Spheres.*

Impact.

§ 180. There remains to be treated, so far as particle dynamics is concerned, the self-contained subject of *Impact*. In connexion with it we must once more refer to the second and third of Newton's laws. We are now dealing with forces which produce, in finite masses, finite changes of momentum in excessively short periods of time. It is clear from this statement that their effects may be treated altogether independently of finite forces, which may be acting along with them, but which produce during the very short periods in question only infinitesimal results. And, as in general we have no knowledge of the actual force exerted at any instant during the impact, nor of the time during which the action lasts, we confine ourselves to the quantity, called the "impulse," which measures the amount of momentum lost by one of the impinging bodies and acquired by the other.

Impulse.

Impact of small spheres.

§ 181. When two balls of glass or ivory impinge on one another, the portions of the surfaces immediately in contact are disfigured and compressed until the molecular reactions thus called into play are sufficient to resist further distortion and compression. At this instant it is evident that the points in contact are moving with the same velocity. But as solids in general possess a certain degree of elasticity both of form and of volume, the balls tend to recover their spherical form, and an additional impulse is generated. This is proportional, as Newton found by experiment, to that exerted during the compression, provided neither of the bodies is permanently distorted. The coefficient of proportionality is a quantity determinable by experiment, and may be conveniently termed the "coefficient of restitution." It is always less than unity.

§ 182. The method of treating questions involving actions of this nature will be best explained by taking as an example the case of *direct impact of one spherical ball on another*. It is evident that in the case of direct impact of smooth or non-rotating spheres we may consider them as mere particles, since everything is symmetrical about the line joining their centres. If the impinging masses are of large dimensions, of the size of the earth, for instance, we cannot treat the effects of the impact independently of the other forces involved; for the duration of collision in such a case may be one of hours instead of fractions of a second.

§ 183. Suppose that a sphere of mass M, moving with a speed $v$, overtakes and impinges on another of mass M', moving in the same straight line with speed $v'$, and that, at the instant when the mutual compression is completed, the spheres are moving with a common speed V. Let R be the impulse during the compression, then

$$M(v-V)=M'(V-v')=R;$$

whence $$V=\frac{Mv+M'v'}{M+M'},\ \text{and}\ R=\frac{MM'}{M+M'}(v-v') \quad . \quad . \quad . \quad (1).$$

From these results we see that the whole momentum after impact is the same as before, and that the common speed is that of the centre of inertia before impact. The quantity V can vanish only if

$$Mv+M'v'=0,$$

that is, if the momenta were originally equal and opposite.

This is the complete solution of the problem if the balls be inelastic, or have no tendency to recover their original form after compression.

§ 184. If the balls be elastic, there will be generated, by their tendency to recover their original forms, an additional impulse proportional to R.

Let $e$ be the coefficient of restitution, and $v_1, v_1'$ the speeds of the balls when finally separated. Then, as before,

$$M(V-v_1)=eR,$$
$$M'(v_1'-V)=eR;$$

whence $$Mv_1=M\frac{Mv+M'v'}{M+M'}-e\frac{MM'}{M+M'}(v-v'),$$

and $$v_1=\frac{(M-eM')v+M'(1+e)v'}{M+M'}=v-\frac{M'}{M+M'}(1+e)(v-v');$$

with a similar expression for $v_1'$.

These results may be more easily obtained by the simple consideration that the whole impulse is $(1+e)R$; for this gives at once $M(v-v_1)=M'(v_1'-v')=(1+e)R$.

Impact on fixed plane.

If M' be infinite, and $v'=0$, we have the result of direct impact on a *fixed* surface, viz., $v-v_1=(1+e)v$ or $v_1=-ev$. The ball rebounds from the fixed surface with a speed $e$ times that with which it impinged.

§ 185. Suppose, now, $M=M'$, $e=1$; that is, let the balls be of equal mass, and their coefficient of restitution unity (or, in the usual but most misleading phraseology, suppose the balls to be "perfectly elastic"); then $2R=M(v-v')$; $v_1=v'$, and similarly $v_1'=v$; or the balls, whatever be their speeds, interchange them, and the motion is the same as if they had passed through one another without exerting any mutual action whatever.

Thus if a number of equal solitaire balls or billiard balls be arranged in contact in a horizontal groove, and another equal ball impinge on one extremity of the row, it is reduced to rest, and the ball at the other end of the row goes off with the original speed of impact. If two impinge, two go off, and so on.

§ 186. We may write the above expressions in terms of the impulse, thus

$$\left.\begin{aligned} v_1&=v-\frac{R(1+e)}{M}\\ v_1'&=v'+\frac{R(1+e)}{M'}\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Hence $Mv_1+M'v_1'=Mv+M'v'$, whatever $e$ be, or there is no momentum lost. This is, of course, a direct consequence of the third law of motion.

Again
$$\tfrac{1}{2}Mv_1^2+\tfrac{1}{2}M'v_1'^2=\tfrac{1}{2}Mv^2+\tfrac{1}{2}M'v'^2$$
$$-R(1+e)(v-v')+\tfrac{1}{2}R^2(1+e)^2\frac{M+M'}{MM'}$$
$$=\tfrac{1}{2}Mv^2+\tfrac{1}{2}M'v'^2-\tfrac{1}{2}R^2(1-e^2)\frac{M+M'}{MM'}$$
$$=\tfrac{1}{2}Mv^2+\tfrac{1}{2}M'v'^2-\tfrac{1}{2}(1-e^2)\frac{MM'}{M+M'}(v-v')^2.$$

Loss of energy.

The last term of the right hand side is therefore the kinetic energy apparently destroyed by the impact. When $e=0$, its magnitude is greatest, and equal to

$$\tfrac{1}{2}\frac{MM'}{M+M'}(v-v')^2=\tfrac{1}{2}R(v-v').$$

When $e=1$, its magnitude is zero; that is, when the coefficient of restitution is unity no kinetic energy is lost.

The kinetic energy which appears to be destroyed in any of these cases is, as we see from § 171, only transformed—partly it may be into heat, partly into sonorous vibrations, as in the impact of a hammer on a bell. But, in spite of this, the elasticity may be "perfect." Hence the absurdity of the designation alluded to in § 185. Also by (2)

$$v_1'-v_1=v'-v+R(1+e)\frac{M+M'}{MM'}$$
$$=e(v-v')\ \text{by (1)}.$$

Hence the velocity of separation is $e$ times that of approach.

§ 187. *Two smooth spheres, moving in given paths and with given speeds, impinge; to determine the impulse and the subsequent motion.*

Let the masses of the spheres be M, M', their speeds before impact $v$ and $v'$, and let the original directions of motion make with the line which joins the centres at the instant of impact the angles $\alpha, \alpha'$, which may be calculated from the data, if the radii of the spheres be given.

Since the spheres are smooth, the entire impulse takes place in the line joining the centres at the instant of impact, and the future motion of each sphere will be in the plane passing through this line and its original direction of motion.

Let R be the impulse, $e$ the coefficient of restitution; then, since the speeds in the line of impact are $v\cos\alpha$ and $v'\cos\alpha'$, we have for their final values $v_1, v_1'$, after restitution, by § 184 the expressions

$$v_1=v\cos\alpha-\frac{M'}{M+M'}(1+e)(v\cos\alpha-v'\cos\alpha'),$$

$$v_1'=v'\cos\alpha'+\frac{M}{M+M'}(1+e)(v\cos\alpha-v'\cos\alpha'),$$

and the value of R is

$$\frac{MM'}{M+M'}(1+e)(v\cos\alpha-v'\cos\alpha').$$

Hence, the sphere M has finally a speed $v_1$ in the line

joining the centres, and a speed $v\sin\alpha$ in a known direction perpendicular to this, namely, in the plane through this and its original direction of motion. And similarly for the sphere M′. Thus the consequences of the impact are completely determined.

§ 188. When a sphere of mass M impinges directly, with speed V, on another M′ at rest, the speed acquired by M′ is

$$\frac{MV(1+e)}{M+M'}.$$

But, if another sphere of mass $\mu$, also at rest, be interposed between them, M′ will acquire a speed

$$\frac{\mu MV(1+e)^2}{(M+\mu)(M'+\mu)}.$$

This is greatest when $\mu$ is the geometric mean of M and M′, and its value is then

$$\frac{MV(1+e)^2}{(\sqrt{M}+\sqrt{M'})^2}.$$

The ratio of this to the speed which M′ would have acquired without the interposition of the third sphere is

$$\frac{1+e}{1+\frac{2\sqrt{MM'}}{M+M'}}.$$

There is thus a gain by the interposition if, and only if,

$$e>\frac{2\sqrt{MM'}}{M+M'}.$$

This condition is always satisfied when the coefficient of restitution is unity, except in the special case of equal masses. If an infinite number of spheres be interposed between M and M′, so adjusted as to give the greatest possible speed to M′, that greatest speed is $V\sqrt{M'/M}$, provided we have $e=1$.

*Continuous Succession of Indefinitely Small Impacts.*

Infinite series of infinitesimal impacts.

§ 189. We may now consider the case of a continuous series of indefinitely small impacts, whose effect is comparable with that of a finite force. One obvious method of considering such a problem is to estimate *separately* the changes in the velocity produced by the finite forces and by the impacts, in the same indefinitely small time $\delta t$, and compound these for the actual effect on the motion in that period.

Another way, of course, is to equate the rate of increase of momentum per unit of time to the force producing it.

*A mass, under no forces, moves through a uniform cloud of little particles which are at rest. Those it meets adhere to it. Find the motion.*

At time $t$ let $\mu$ be the mass, and let $x$ denote its position in its line of motion. Then, as there is no loss of momentum, we have

$$\frac{d}{dt}(\mu\dot{x})=0.$$

But if M be the original mass, $\mu_0$ the mass of the particles picked up in unit of length, obviously

$$\mu=M+\mu_0 x.$$

Substitute and integrate, supposing $x=0$, $\dot{x}=V$, when $t=0$; and we get

$$(M+\mu_0 x)\dot{x}=MV,$$

from which $x$ can be easily found.

It is interesting to observe that we have

$$\ddot{x}=-\frac{\mu_0 M^2V^2}{(M+\mu_0 x)^3};$$

so that the mass moves as if acted on by an attraction varying inversely as the cube of the distance from a point in its line of motion.

This problem obviously leads to the same result as the following:—*A cannon-ball attached to one end of a chain, which is coiled up on a smooth horizontal plane, is projected along the plane. Determine its motion.*

§ 190. Another excellent instance of the application of this process is furnished by the motion of a rocket, where the motive power depends on the fact that a portion of the mass is detached with considerable relative velocity. The increase of the momentum of the rocket due to this cause is equal to the relative momentum with which the products of combustion escape. If we suppose the rocket, originally of mass M, to lose $e$M in unit of time, projected from it with relative velocity V, the gain of momentum in time $\delta t$ due to this cause is

$$eMV\delta t.$$

The total upward acceleration is therefore

$$\frac{eMV}{M-eMt}-g$$

Unless this be positive the rocket cannot rise. It will rise at once if $V>g/e$, and it cannot rise at all unless $MV/M'>g/e$, M′ being the mass of the case, stick, &c., which are not burned away.

From the above data it is easy to calculate that the greatest speed acquired during the flight (the resistance of the air being left out of account) is

$$V\log\frac{M}{M'}-\frac{g}{e}\left(1-\frac{M'}{M}\right).$$

*Dynamics of a System of Particles Generally.*

Motion of a system of particles.

§ 191. The law of energy, in abstract dynamics, may be expressed as follows:—the whole work done in any time, on any limited material system, by applied forces, is equal to the whole effect in the forms of potential and kinetic energy produced in the system, together with the work lost in friction. This principle may be regarded as comprehending the whole of abstract dynamics, because the conditions of equilibrium and of motion, in every possible case, may be derived from it.

Condition of equilibrium.

§ 192. A material system, whose relative motions are unresisted by friction, is in equilibrium in any configuration if, and is not in equilibrium unless, the rate at which the applied forces perform work at the instant of passing through it is equal to that at which potential energy is gained, in every possible motion through that configuration. This is the celebrated principle of "virtual velocities," which Lagrange made the basis of his *Mécanique Analytique*.

Virtual velocities.

§ 193. To prove it, we have first to remark that the system cannot possibly move away from any particular configuration except by work being done upon it by the forces to which it is subject; it is therefore in equilibrium if the stated condition is fulfilled. To ascertain that nothing less than this condition can secure the equilibrium, let us first consider a system having only one degree of freedom to move. Whatever forces act on the whole system, we may always hold it in equilibrium by a single force applied to any one point of the system in its line of motion, opposite to the direction in which it tends to move, and of such magnitude that, in any infinitely small motion in either direction, it shall resist or shall do as much work as the other forces, whether applied or internal, altogether do or resist. Now, by the principle of superposition of forces in equilibrium, we might, without altering their effect, apply to any one point of the system such a force as we have just seen would hold the system in equilibrium, and another force equal and opposite to it. All the other forces being balanced by one of these two, they and it might again, by the principle of superposition of forces in equilibrium, be removed; and therefore the whole set of given forces would produce the same effect, whether for equilibrium or for motion, as the single force which is left acting alone. This single force, since it is in a line in which the point of its application is free to move, must move the system. Hence the given forces, to which the single force has been proved equivalent, cannot possibly be

in equilibrium unless their whole work for an infinitely small motion is nothing, in which case the single equivalent force is reduced to nothing. But whatever amount of freedom to move the whole system may have, we may always, by the application of frictionless constraint, limit it to one degree of freedom only; and this may be freedom to execute any particular motion whatever, possible under the given conditions of the system. If, therefore, in any such infinitely small motion there is variation of potential energy uncompensated by work of the applied forces, constraint limiting the freedom of the system to only this motion will bring us to the case in which we have just demonstrated there cannot be equilibrium. But the application of constraints limiting motion cannot possibly disturb equilibrium, and therefore the given system under the actual conditions cannot be in equilibrium in any particular configuration if the rate of doing work is greater than that at which potential energy is stored up in any possible motion through that configuration.

Neutral equilibrium.

§ 194. If a material system, under the influence of internal and applied forces, varying according to some definite law, is balanced by them in any position in which it may be placed, its equilibrium is said to be neutral. This is the case with any spherical body of uniform material resting on a horizontal plane. A right cylinder or cone, bounded by plane ends perpendicular to the axis, is also in neutral equilibrium on a horizontal plane. Practically, any mass of moderate dimensions is in neutral equilibrium when its centre of inertia only is fixed, since, when its longest dimension is small in comparison with the earth's radius, the action of gravity is, as we shall see (§ 222), approximately equivalent to a single force through this point.

Stable equilibrium.

§ 195. But if, when displaced infinitely little in any direction from a particular position of equilibrium, and left to itself, it commences and continues vibrating, without ever experiencing more than infinitely small deviation, in any one of its parts, from the position of equilibrium, the equilibrium in this position is said to be stable. A weight suspended by a string, a uniform sphere in a hollow bowl, a loaded sphere resting on a horizontal plane with the loaded side lowest, an oblate body resting with one end of its shortest diameter on a horizontal plane, a plank, whose thickness is small compared with its length and breadth, floating on water, are all cases of stable equilibrium,—if we neglect the motions of rotation about a vertical axis in the second, third, and fourth cases, and horizontal motion in general in the fifth, for all of which the equilibrium is neutral.

Unstable equilibrium.

§ 196. If, on the other hand, the system can be displaced in any way from a position of equilibrium, so that when left to itself it will not vibrate within infinitely small limits about the position of equilibrium, but will move farther and farther away from it, the equilibrium in this position is said to be unstable. Thus a loaded sphere resting on a horizontal plane with its load as high as possible, an egg-shaped body standing on one end, a board floating edgewise in water, would present, if they could be realized in practice, cases of unstable equilibrium.

§ 197. When, as in many cases, the nature of the equilibrium varies with the direction of displacement, if unstable for any possible displacement it is practically unstable on the whole. Thus a circular disk standing on its edge, though in neutral equilibrium for displacements in its plane, yet being in unstable equilibrium for those perpendicular to its plane, is practically unstable. A sphere resting in equilibrium on a saddle presents a case in which there is stable, neutral, or unstable equilibrium according to the direction in which it may be displaced by rolling; but practically it is unstable.

§ 198. The theory of energy shows a very clear and simple test for discriminating these characters, or determining whether the equilibrium is neutral, stable, or unstable, in any case. If there is just as much potential energy stored up as there is work performed by the applied and internal forces in any possible displacement, the equilibrium is neutral, but not unless. If in every possible infinitely small displacement from a position of equilibrium there is more potential energy stored up than work done, the equilibrium is thoroughly stable, and not unless. If in any or in every infinitely small displacement from a position of equilibrium there is more work done than energy stored up, the equilibrium is unstable. It follows that if the system is influenced only by internal forces, or if the applied forces follow the law of doing always the same amount of work upon the system while passing from one configuration to another by all possible paths, the whole potential energy must be constant in all positions for neutral equilibrium, must be a minimum for positions of thoroughly stable equilibrium, and must be either a maximum for all displacements or a maximum for some displacements and a minimum for others when there is unstable equilibrium.

Energy-test of equilibrium.

§ 199. We have seen that, according to D'Alembert's principle, as explained above, forces acting on the different points of a material system, and their reactions against the accelerations which they actually experience in any case of motion, are in equilibrium with one another. Hence, in any actual case of motion, not only is the actual work by the forces equal to the kinetic energy produced in any infinitely small time, in virtue of the actual accelerations, but so also is the work which would be done by the forces, in any infinitely small time, if the velocities of the points constituting the system were at any instant changed to any possible infinitely small velocities, and the accelerations unchanged. This statement, when put into the concise language of mathematical analysis, constitutes Lagrange's application of the "principle of virtual velocities" to express the conditions of D'Alembert's equilibrium between the forces acting and the resistances of the masses to the acceleration. It comprehends, as we have seen, every possible condition of every case of motion. The "equations of motion" in any particular case are, as Lagrange has shown, deduced from it with great ease.

Formation of general equation of motion.

Commencing again with the equations of motion of a particle

$$m\ddot{x} = X + X', \quad m\ddot{y} = Y + Y', \quad m\ddot{z} = Z + Z',$$

let us introduce quantities $\delta x$, &c., consistent with the conditions, otherwise perfectly arbitrary, and we have the general equation

$$\Sigma m(\ddot{x}\delta x + \ldots) = \Sigma(X\delta x + \ldots),$$

in which, by D'Alembert's principle, the forces X', Y', Z', due to the constraints, do not appear.

If the system be conservative the right-hand member of this is, of course, equal to the loss of potential energy, so that

$$-\delta V = \Sigma(X\delta x + \ldots),$$

and therefore, quite generally in such a system,

$$\Sigma m(\ddot{x}\delta x + \ldots) = -\delta V. \qquad \{1\}$$

In the actual motion of any system we have, for each particle, $\delta x = \dot{x}\delta t$, &c., so that we have

$$\Sigma m(\ddot{x}\dot{x} + \ddot{y}\dot{y} + \ddot{z}\dot{z}) = \Sigma(X\dot{x} + Y\dot{y} + Z\dot{z}).$$

This is the complete statement of Newton's scholium, § 2 above.

The right-hand member is the expression of the algebraic sum of the *actiones agentium* and of the *reactiones resistentium*, so far as these depend upon gravity, friction, &c., and the left-hand member that of the *reactiones* due to the accelerations of the several particles.

If the system be conservative, this becomes

$$\Sigma m(\ddot{x}\dot{x} + \ddot{y}\dot{y} + \ddot{z}\dot{z}) = -\frac{dV}{dt},$$

whose integral

$$\tfrac{1}{2}\Sigma m(\dot{x}^2 + \dot{y}^2 + \dot{z}^2) + V = H$$

is of course the general statement of the conservation of energy.

In Lagrange's general equation above, as we have stated, the variations $\delta x$, &c., are not usually independent. We must take account of the various constraints imposed on the system. If these

retain the same character throughout the motion they may be expressed by a (generally finite) number of equations of the form

$$f(x_1, y_1, z_1, x_2, y_2, z_2, \ldots) = 0.$$

Each of these gives rise to a purely kinematical relation affecting some one or more of the quantities $\delta x$, &c., of the form

$$\Sigma\left(\left(\frac{df}{dx}\right)\delta x + \left(\frac{df}{dy}\right)\delta y + \ldots\right) = 0.$$

By introducing, as usual, a set of undetermined multipliers $\mu$, one for each of the conditions of constraint, we obtain on adding all these equations to the general equation above

$$\Sigma m(\ddot{x}\delta x + \ldots) = \Sigma\left[\left(X + \mu\left(\frac{df}{dx}\right) + \mu_1\left(\frac{df_1}{dx}\right) + \ldots\right)\delta x + \ldots\right] \quad (2).$$

If there be $p$ particles of the system, there are $3p$ coordinates $x$, $y$, $z$, connected by (say) $q$ equations of constraint, so that there are $3p-q$ degrees of freedom, and therefore $3p-q$ independent coordinates.

Equating separately to zero the multipliers of $\delta x_1$, $\delta y_1$, &c., in the resultant equation above, we have $3p$ equations of which we write only one as a type, viz.,

$$m\ddot{x} = X + \Sigma\mu\left(\frac{df}{dx}\right) \quad (3).$$

Taken along with the $q$ equations of the form

$$f = 0$$

these form a group of $3p+q$ equations, theoretically necessary and sufficient to determine the $3p$ quantities $x_1$, $y_1$, $z_1$, &c., and the $q$ quantities $\mu$, in terms of $t$. Thus we have the complete analytical statement of the conditions, and the rest of the solution is a question of pure mathematics.

Non-conservative system.

When we deal with a non-conservative system (which is equivalent in nature to saying "when we take an incomplete view of the question"), some of the conditions may vary in character during the motion. This will be expressed analytically by the entrance of $t$ explicitly into one or more of the equations of condition $f$. But, if we think of the mode of formation of Lagrange's equation, we see that it was built up of separate equations, such as

$$m\ddot{x} = X + X',$$

which are true whether the equations of condition involve $t$ explicitly or not. Each of these was multiplied by a quantity $\delta x$, &c., the only limitation on which was that it should be consistent with the conditions of the system at the instant considered, whatever instant that might be. Hence equation (2) still holds good.

When, however, we introduce in that equation multipliers corresponding to the actual motion of the system, so that

$$\delta x = \dot{x}\delta t, \text{ &c.},$$

we find a remarkably simple expression for the energy given to, or withdrawn from, the system in consequence of the varying conditions. For the unintegrated equation (2) now becomes

$$\frac{d}{dt}(\tfrac{1}{2}\Sigma m(\dot{x}^2 + \dot{y}^2 + \dot{z}^2)) = \Sigma(X\dot{x} + Y\dot{y} + Z\dot{z}) - \Sigma\mu\left(\frac{df}{dt}\right),$$

where the differential coefficient of $f$ is partial. This follows at once from equations of the form

$$\frac{df}{dt} = \left(\frac{df}{dt}\right) + \left(\frac{df}{dx}\right)\dot{x} + \text{&c.} = 0$$

which are obtained by differentiating the equations of condition with regard to $t$. When the conditions do not vary, the quantities $\left(\frac{df}{dt}\right)$, &c., all vanish, and we see that the constraint does not alter the energy of the system.

## *Least and Varying Action.*

Action.

§ 200. To complete our sketch of kinetics of a particle we will now briefly consider the important quantity called "action." This, for a single particle, may be defined either as the space integral of the momentum or as double the time integral of the kinetic energy, calculated from any assumed position of the moving particle, or from an assigned epoch. For a system its value is the sum of its separate values for the various particles of the system. No one has, as yet, pointed out (in the simple form in which it is all but certain that they can be expressed) the true relations of this quantity. It was originally introduced into kinetics to suit the metaphysical necessity that something should be a minimum in the path of a luminous corpuscle (see an extract from Hamilton in the article LIGHT, vol. xiv. p. 598). But there can be little doubt that it is destined to play an important part in the final systematizing of the fundamental laws of kinetics.

The importance of the quantity called action, so far as is at present known, depends upon the two principles of "least action" and of "varying action," the first as old as Maupertuis, the other discovered by Hamilton about half a century ago.

Least action.

The first is—*If the sum of the potential and kinetic energies of a system is the same in all its configurations, then, of all the sets of paths by which the parts of the system can be guided by frictionless constraint to pass from one given configuration to another, that one for which the action is least is the natural one or requires no constraint.*

§ 201. Unfortunately it is not easy to give examples of this important principle which can be satisfactorily treated by elementary methods,—except, indeed, the very simplest, such as those furnished by the corpuscular theory of light. Thus it is obvious that, as long as a medium is homogeneous and isotropic, the speed of a corpuscle in it is constant. The action is thus reduced to the product of the constant speed of the corpuscle by the length of its path. Hence the principle at once shows that the path must be a straight line. When the corpuscle is refracted from one such medium into another, the path is a broken line such that the product of each of its parts by the corresponding speed of the corpuscle is the least possible. This gives the law of the sines, but to agree with experiment the speed would have to be greater in the denser medium than in the rarer.

Change of action.

§ 202. The problem *to find change of action as depending on change (nowhere finite) of the mode of passage from one given configuration to another* (restricted by the condition already mentioned), is expressed mathematically by

$$\delta A = \delta\int\Sigma m\dot{s}ds = \delta\int\Sigma m(\dot{x}dx + \dot{y}dy + \dot{z}dz),$$

while

$$T = \tfrac{1}{2}\Sigma m\dot{s}^2 = \tfrac{1}{2}\Sigma m(\dot{x}^2 + \dot{y}^2 + \dot{z}^2) = H - V,$$

H being the constant energy of the system, and the integral being taken between limits supplied by the two given configurations.

The first equation gives

$$\delta A = \int\Sigma m(dx\delta\dot{x} + dy\delta\dot{y} + dz\delta\dot{z} + \dot{x}d\delta x + \dot{y}d\delta y + \dot{z}d\delta z)$$
$$= \Sigma m(\dot{x}\delta x + \ldots) + \int\Sigma m(d\dot{x}\delta x + d\dot{y}\delta y + d\dot{z}\delta z - d\dot{x}\delta x - d\dot{y}\delta y - d\dot{z}\delta z)$$

by partial integration. But the integrated part

$$\Sigma m(\dot{x}\delta x + \dot{y}\delta y + \dot{z}\delta z), \quad (A)$$

obviously vanishes at both limits, because the initial and final configurations are given.

If we now take the corresponding variation of the expressions for the kinetic energy, we have

$$\delta T = \Sigma m\dot{s}\delta\dot{s} = \Sigma m(\dot{x}\delta\dot{x} + \dot{y}\delta\dot{y} + \dot{z}\delta\dot{z})$$

from which we have

$$\int\Sigma m(d\dot{x}\delta\dot{x} + d\dot{y}\delta\dot{y} + d\dot{z}\delta\dot{z}) = \int\delta T dt.$$

Also we have

$$d\dot{x}\delta x + d\dot{y}\delta y + d\dot{z}\delta z = (\ddot{x}\delta x + \ddot{y}\delta y + \ddot{z}\delta z)dt;$$

so that finally

$$\delta A = \int dt\left[\delta T - \Sigma m(\ddot{x}\delta x + \ddot{y}\delta y + \ddot{z}\delta z)\right],$$

which so far is a mere kinematical result. But it can be rendered physical by putting $-\delta V$ for $\delta T$, in accordance with the above condition. This we will suppose done.

If now we desire to make $\delta A$ vanish, so as to obtain what is called the "stationary condition," we must make the factor in square brackets in the integral vanish; *i.e.*, we must have

$$\Sigma m(\ddot{x}\delta x + \ddot{y}\delta y + \ddot{z}\delta z) + \delta V = 0$$

for all admissible simultaneous values of $\delta x$, $\delta y$, $\delta z$ for the various particles of the system. But this is precisely the general equation which, as we found in § 199 (1), determines the undisturbed motion of the system.

§ 203. The expression $\delta A = 0$ really signifies that any infinitesimal change from the natural mode of passage produces an infinitely smaller change in the corresponding amount of the action between the terminal configurations.

§ 204. It will be noticed that the essential characteristic of the modes of passage considered in this investigation is that all shall have the same terminal configurations, and that the system shall

Varying action.

always have the same definite amount of energy. All, except the natural mode of passage, in general require constraint in order that they may be described. Hamilton's grand extension of the subject depended on comparing the actions in a number of *natural* modes of passage, differing from one another by slight changes in their terminal configurations, and slight changes in the whole initial energy.

In this new form of statement the unintegrated part of the expression for $\delta A$ vanishes, since all the modes of passage contemplated are natural. The alteration of the whole energy, however, adds a special term to the equation, and we can at once write, from the expression (A) § 202, the equation for the change in the action under the new conditions, viz.,

$$\delta A = \left[\Sigma m(\dot{x}\delta x + \dot{y}\delta y + \dot{z}\delta z)\right] + t\delta H ,$$

the part in brackets having to be taken between limits corresponding to the terminal configurations, and the variations $\delta x$, $\delta y$, $\delta z$ at these being subject to the conditions of the system.

We cannot here consider this equation in its general form. We content ourselves with the simpler special deductions from it required for completing our sketch of Kinetics of a Particle.

The last given equation, written in full for a single particle of unit mass, is

$$\delta A = [\dot{x}\delta x + \dot{y}\delta y + \dot{z}\delta z] - (\dot{x}_0\delta x_0 + \dot{y}_0\delta y_0 + \dot{z}_0\delta z_0) + t\delta H ,$$

where $x_0$, $y_0$, $z_0$ is the initial point, and $x$, $y$, $z$ any other point, of the path. If the particle be altogether free, the seven variations on the right-hand side are independent of one another; and thus we have the following remarkable properties of the quantity A, regarded as a function of seven independent variables (the initial and final coordinates of the particle, and its constant energy), viz.,

$$\left(\frac{dA}{dx}\right) = \frac{dx}{dt}, \quad \left(\frac{dA}{dx_0}\right) = -\frac{dx_0}{dt},$$
$$\left(\frac{dA}{dy}\right) = \frac{dy}{dt}, \quad \left(\frac{dA}{dy_0}\right) = -\frac{dy_0}{dt},$$
$$\left(\frac{dA}{dz}\right) = \frac{dz}{dt}, \quad \left(\frac{dA}{dz_0}\right) = -\frac{dz_0}{dt},$$
$$\left(\frac{dA}{dH}\right) = t .$$

From these we gather at once that A satisfies the partial differential equations

$$\left(\frac{dA}{dx}\right)^2 + \left(\frac{dA}{dy}\right)^2 + \left(\frac{dA}{dz}\right)^2 = v^2 = 2(H - V) \quad . \quad . \quad (1),$$
$$\left(\frac{dA}{dx_0}\right)^2 + \left(\frac{dA}{dy_0}\right)^2 + \left(\frac{dA}{dz_0}\right)^2 = v_0^2 = 2(H - V_0) \quad . \quad . \quad (2).$$

Characteristic function.

§ 205. The whole circumstances of the motion are thus dependent on the function A, called by Hamilton the "characteristic function." The determination of this function is troublesome, even in very simple cases of motion; but the fact that such a mode of representation is possible is extremely remarkable.

§ 206. More generally, omitting all reference to the initial point, and the equation § 204 (2) which belongs to it, let us consider A simply as a function of $x$, $y$, $z$. Then

*Any function, A, which satisfies the partial differential equation*

$$\left(\frac{dA}{dx}\right)^2 + \left(\frac{dA}{dy}\right)^2 + \left(\frac{dA}{dz}\right)^2 = v^2 = 2(H - V) \quad . \quad . \quad . \quad (1),$$

*possesses the property that* $\frac{dA}{dx}$, $\frac{dA}{dy}$, $\frac{dA}{dz}$ *represent the rectangular components of the velocity of a particle in a motion possible under the forces whose potential is V.*

For, by partial differentiation of (1) we have

$$\frac{d}{dt}\left(\frac{dx}{dt}\right) = \frac{d^2x}{dt^2} = X = -\frac{dV}{dx} = -\frac{dA}{dx}\frac{d^2A}{dx^2} - \frac{dA}{dy}\frac{d^2A}{dxdy} - \frac{dA}{dz}\frac{d^2A}{dxdz},$$

with other two equations of the same form.

But we have also three equations of the form

$$\frac{d}{dt}\left(\frac{dA}{dx}\right) = \frac{dx}{dt}\frac{d^2A}{dx^2} + \frac{dy}{dt}\frac{d^2A}{dxdy} + \frac{dz}{dt}\frac{d^2A}{dxdz}.$$

Comparing, we see that

$$\frac{dx}{dt} = \frac{dA}{dx}, \quad \frac{dy}{dt} = \frac{dA}{dy}, \quad \frac{dz}{dt} = \frac{dA}{dz}$$

satisfy simultaneously the two sets of equations.

§ 207. Also if $\alpha$, $\beta$ be constants, which, along with H, are involved in a complete integral of the above partial differential equation *the corresponding path, and the time of its description, are given by*

$$\left(\frac{dA}{d\alpha}\right) = \alpha_1, \quad \left(\frac{dA}{d\beta}\right) = \beta_1, \quad \left(\frac{dA}{dH}\right) = t + \epsilon,$$

*where* $\alpha_1$, $\beta_1$, $\epsilon$ *are three additional arbitrary constants.*

For these equations give, by complete differentiation with regard to $t$,

$$\left.\begin{aligned} \frac{d^2A}{dxd\alpha}\frac{dx}{dt} + \frac{d^2A}{dyd\alpha}\frac{dy}{dt} + \frac{d^2A}{dzd\alpha}\frac{dz}{dt} &= 0 \\ \frac{d^2A}{dxd\beta}\frac{dx}{dt} + \frac{d^2A}{dyd\beta}\frac{dy}{dt} + \frac{d^2A}{dzd\beta}\frac{dz}{dt} &= 0 \\ \frac{d^2A}{dxdH}\frac{dx}{dt} + \frac{d^2A}{dydH}\frac{dy}{dt} + \frac{d^2A}{dzdH}\frac{dz}{dt} &= 1 \end{aligned}\right\} \quad . \quad . \quad . \quad (a).$$

But, differentiating § 206 (1) with respect to $\alpha$, $\beta$, H respectively, we get

$$\left.\begin{aligned} \frac{d^2A}{d\alpha dx}\frac{dA}{dx} + \frac{d^2A}{d\alpha dy}\frac{dA}{dy} + \frac{d^2A}{d\alpha dz}\frac{dA}{dz} &= 0 \\ \frac{d^2A}{d\beta dx}\frac{dA}{dx} + \frac{d^2A}{d\beta dy}\frac{dA}{dy} + \frac{d^2A}{d\beta dz}\frac{dA}{dz} &= 0 \\ \frac{d^2A}{dHdx}\frac{dA}{dx} + \frac{d^2A}{dHdy}\frac{dA}{dy} + \frac{d^2A}{dHdz}\frac{dA}{dz} &= 1 \end{aligned}\right\} \quad . \quad . \quad . \quad (b).$$

The values of $\frac{dx}{dt}$, &c., in ($a$) are evidently equal respectively to those of $\frac{dA}{dx}$, &c., in ($b$). Hence the proposition.

Surfaces of equal action.

§ 208. "Equiactional surfaces," *i.e.*, those whose common equation is

$$A = \text{const.},$$

are cut at right angles by the trajectories.

For the direction cosines of the normal are obviously proportional to

$$\left(\frac{dA}{dx}\right), \left(\frac{dA}{dy}\right), \left(\frac{dA}{dz}\right), \text{ that is, to } \frac{dx}{dt}, \frac{dy}{dt}, \frac{dz}{dt}.$$

Thus the determination of equiactional surfaces is resolved into the problem of finding the orthogonal trajectories of a set of given curves in space, whenever the conditions of the motion are given.

*The distance between consecutive equiactional surfaces is, at any point, inversely as the velocity in the corresponding path.*

This may be seen at once as follows: the element of the action, which is the same at all points, is $v\delta s$ (where $\delta s$, being an element of the path, is the normal distance between the surfaces).

Planetary motion.

§ 209. In consequence of the importance of the method we will take two examples of its application. First a direct example, then one depending on the equiactional surfaces.

*To deduce from the principle of "varying action" the form and mode of description of a planet's orbit.*

In this case it is obvious that $-\frac{dV}{dr}$ represents the attraction of gravity ($-\mu/r^2$). Hence the right-hand member of § 206 (1) may be written $2(H + \mu/r)$.

Let us take the plane of $xy$ as that of the orbit, then the equation § 206 (1) becomes

$$v^2 = \left(\frac{dA}{dx}\right)^2 + \left(\frac{dA}{dy}\right)^2 = 2\left(H + \frac{\mu}{r}\right) \quad . \quad . \quad . \quad . \quad (1).$$

It is not difficult to obtain a satisfactory solution of this equation, but the operation is very much simplified by the use of polar coordinates. With this change, (1) becomes

$$\left(\frac{dA}{dr}\right)^2 + \frac{1}{r^2}\left(\frac{dA}{d\theta}\right)^2 = 2\left(H + \frac{\mu}{r}\right) \quad . \quad . \quad . \quad . \quad (2),$$

which is obviously satisfied by

$$\left.\begin{aligned} \left(\frac{dA}{d\theta}\right) &= \text{constant} = \alpha, \\ \left(\frac{dA}{dr}\right)^2 &= 2\left(H + \frac{\mu}{r}\right) - \frac{\alpha^2}{r^2} \end{aligned}\right\} \quad . \quad . \quad . \quad (3).$$

Hence
$$A = \alpha\theta + \int dr \sqrt{2(H + \mu/r) - \alpha^2/r^2} \quad . \quad . \quad . \quad . \quad (4).$$

The final integrals are therefore, by § 207,

$$\left(\frac{dA}{d\alpha}\right) = \alpha_1 = \theta - \alpha \int \frac{dr}{r^2\sqrt{2(H + \mu/r) - \alpha^2/r^2}} \quad . \quad . \quad (5),$$

and
$$\left(\frac{dA}{dH}\right) = t + \epsilon = \int \frac{dr}{\sqrt{2(H + \mu/r) - \alpha^2/r^2}} \quad . \quad . \quad . \quad (6).$$

These equations contain the complete solution of the problem, for they involve four constants, $\alpha_1$, $\alpha$, H, $\epsilon$. (5) gives the equation of the orbit, and (6) the time in terms of the radius-vector.

To complete the investigation, let us assume

$$\mu/\alpha^2 = 1/l, \qquad 2H\alpha^2/\mu^2 = (e^2 - 1)/l^2$$

where $l$ and $e$ are two new arbitrary constants introduced in place of $a$ and H. With these (5) becomes

$$a_1 = \theta - \int \frac{dr}{r^2\sqrt{(e^2-1)/l^2 + 2/lr - 1/r^2}}$$

$$= \theta - \int \frac{dr}{r^2\sqrt{e^2/l^2 - (1/r - 1/l)^2}} = \theta - \cos^{-1}\frac{l}{e}(r^{-1} - l^{-1}),$$

or

$$r = \frac{l}{1 + e\cos(\theta - a_1)},$$

the general polar equation of conic sections referred to the focus.

Also by differentiating (5) with respect to $r$, we have

$$\frac{a\,dr}{r^2\sqrt{2(H + \mu/r) - a^2/r^2}} = d\theta,$$

from which, by (6), we immediately obtain

$$t + \epsilon = \frac{1}{a}\int r^2 d\theta = \frac{1}{\sqrt{\mu l}}\int r^2 d\theta.$$

This involves, again, the equation of equable description of areas. Compare § 144.

Action in orbit of planet.

§ 210. In a planet's elliptic orbit *the time is measured by the area described about one focus, and the action by that described about the other.*

For with the usual notation we have

$$dA = v\,ds = \frac{h}{p}\,ds,$$

by the result of § 47. But in the ellipse or hyperbola, $p'$ being the perpendicular from the second focus,

$$pp' = \pm b^2.$$

Hence

$$dA = \pm\frac{h}{b^2}p'\,ds,$$

which expresses the result stated above.

It is easy to extend this to a parabolic orbit, for which, indeed, the theorem is even more simple.

Example.

§ 211. *Unit particles are projected simultaneously and horizontally in all directions from every point of a vertical axis, all having the same total energy at starting; find the surfaces of equal action.*

We may obviously confine ourselves to a plane section through the axis. Let $x$ be the vertical coordinate of a particle, measured downwards from the level at which the common energy is wholly potential, $k$ the coordinate of the point in the axis from which it was projected. Then we have, after the lapse of time $t$,

$$\left.\begin{aligned} x &= k + \tfrac{1}{2}gt^2 \\ y &= \sqrt{2gk}\,t \end{aligned}\right\}.$$

Eliminating $t$, we have the equation of the parabolic path—

$$x = k + \frac{y^2}{4k}.$$

To find the orthogonal trajectory (the meridian section of the surface of equal action), differentiate, put $-\frac{dx}{dy}$ for $\frac{dy}{dx}$, and eliminate $k$. We thus have

$$-\frac{dy}{dx} = \frac{y}{2k} = \frac{y}{x + \sqrt{x^2 - y^2}} = \frac{\sqrt{x+y} - \sqrt{x-y}}{\sqrt{x+y} + \sqrt{x-y}}$$

or

$$-\sqrt{x+y}(dx+dy) + \sqrt{x-y}(dx-dy) = 0,$$

so that

$$(x+y)^{\frac{1}{2}} \pm (x-y)^{\frac{1}{2}} = \text{const.}$$

If we turn the axes through $\frac{1}{4}\pi$ in their own plane, the coordinates being now $\xi$ and $\eta$, this equation becomes

$$\xi^{\frac{1}{2}} + \eta^{\frac{1}{2}} = a^{\frac{1}{2}}.$$

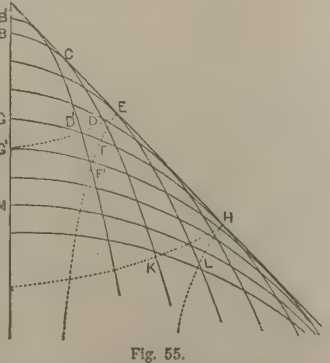

Fig. 55.

In fig. 55, AM is the axis. A few of the paths are shown by full lines, and two of the sections of surfaces of equal action by dotted lines. These sections indicate cusps lying on the line AH, which makes an angle $\frac{1}{4}\pi$ with the vertical, and is touched by all the paths. The path whose vertex is G touches this line in H, and therefore passes through the cusp of which the branches are HK and HL. HK belongs to all paths whose vertices are above G, HL to those (such as ML) whose vertices are below G.

It is worthy of note that, by the first equations above,

$$x \pm y = (\sqrt{k} \pm \sqrt{\tfrac{1}{2}g}.t)^2,$$

by the substitution of which in the equation of action we see how the time of reaching a particular surface of equal action depends upon the position of the starting point.

Plane currents.

§ 212. A very interesting plane example, which has elegant applications in fluid motion, and in the conduction of electric currents in plates of uniform thickness, is furnished by assuming

$$A = \log r, \text{ or } A' = \theta,$$

where $r$ and $\theta$ are the polar coordinates of the moving particle.

In the former, where the curves of equal action are circles with the origin as centre, we have

$$\frac{dA}{dx} = \dot{x} = \frac{x}{r^2}, \qquad \frac{dA}{dy} = \dot{y} = \frac{y}{r^2},$$

so that the paths are radii vectores described with velocity $1/r$. Also we have

$$2(H - V) = \left(\frac{dA}{dx}\right)^2 + \left(\frac{dA}{dy}\right)^2 = \frac{1}{r^2};$$

so that the force is central, and its value is

$$-\frac{dV}{dr} = -\frac{1}{r^3}.$$

In the second case, where the curves of equal action are radii drawn from the pole and

$$A' = \theta = \tan^{-1}\frac{y}{x},$$

we have

$$\frac{dA'}{dx} = \dot{x} = -\frac{y}{r^2}, \quad \frac{dA'}{dy} = \dot{y} = \frac{x}{r^2}$$

The kinetic energy is still $1/2r^2$, and the central force $-1/r^3$, but the paths are circles with the origin as centre. Thus the lines of equal action and the paths of individual particles are convertible.

We have also, in each of these cases,

$$\left(\frac{d\dot{x}}{dx}\right) + \left(\frac{d\dot{y}}{dy}\right) = 0.$$

This shows (as in § 94) that, whatever be originally the grouping of a set of particles moving all according to one or other of these conditions, the density at any part of the group remains unchanged during the motion. In fact, as it is easy to prove, A and A' are elementary solutions of the partial differential equation

$$\frac{d^2A}{dx^2} + \frac{d^2A}{dy^2} = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1);$$

and they are conjugate, in the sense that

$$\frac{dA}{dx} = \frac{dA'}{dy}, \quad \frac{dA}{dy} = -\frac{dA'}{dx}.$$

For this reason the paths belonging to the two systems are everywhere orthogonal to one another.

Also, as the differential equation (1) for A is linear, any linear function of particular integrals is an integral. Thus, for instance, we may take ($p$ being any constant)

$$A = \log r - p\theta,$$

with

$$A' = p\log r + \theta.$$

These, representing orthogonal sets of logarithmic spirals, possess the same properties with regard to action as did the concentric circles and their radii, which, in fact, are the mere particular case when $p = 0$.

Graphic method.

§ 213. It is easy to give graphic methods of tracing these curves of action by means of an old process recently much developed by Clerk Maxwell. The present example, though a very simple one, is quite sufficient to illustrate the process.

Draw, as in fig. 56, a set of circles whose radii are $\varepsilon^a$, $\varepsilon^{2a}$, $\varepsilon^{3a}$, &c., and a set of radii vectores making with the initial line the successive angles, $\frac{a}{p}$, $2\frac{a}{p}$, $3\frac{a}{p}$, &c., $a$ being a quantity which may have any convenient value. These lines will form a network, finer as $a$ is smaller. Now suppose we wish to trace the curve

$$A = na.$$

We take the intersection of the circle whose radius is $\varepsilon^{sa}$ with the radius-vector corresponding to the angle

$$(s-n)\frac{a}{p}.$$

Thus we have for the value of A at the point of intersection

$$A = \log\varepsilon^{sa} - p\frac{s-n}{p}a$$

$$= na, \text{ as required.}$$

By marking the intersections corresponding to different values of $s$ we have a series of points in the required curve which, by adjust

ment of the value of $a$, may be made to lie as close together as is found necessary for tracing the curve of action through them *liberâ manu*.

In fig. 56 portions of three separate sets of mutually orthogonal logarithmic spirals have been traced, by using the intersections of the fundamental straight lines and circles.

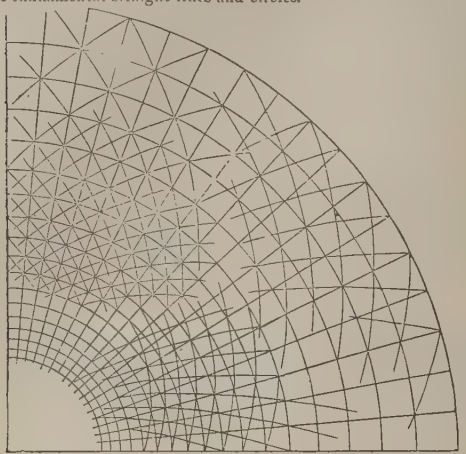

Fig. 56.

We may pursue the subject much farther, by combining particular solutions like those given but taken from different origins. We can afford space for one only. Let P, Q (fig. 57) be points on the axis of $x$, distant $a$ and $-a$ from the origin, R any point in the plane of the figure. Let $PR=r$, $\angle RPx=\theta$, $RQ=r_1$, $\angle RQx=\theta_1$.

Then if

$$A=\log r-\log r_1,$$
$$A'=\theta-\theta_1,$$

we must have, not only the equation

$$\frac{d^2A}{dx^2}+\frac{d^2A}{dy^2}=0$$

satisfied by each of A and A', but also the conditions

$$\frac{dA}{dx}=\frac{dA'}{dy},\quad \frac{dA}{dy}=-\frac{dA'}{dx}.$$

This follows at once from the fact that all the equations are linear.

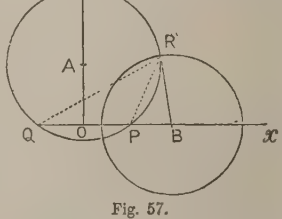

Fig. 57.

§ 214. In fig. 57 we have $\epsilon^A=PR/QR$. Hence the locus of R is a circle, whose centre, B, is on QP produced.

Again $A'=\angle RPx-\angle RQx=\angle PRQ$. The locus of R is, in this case, any circle passing through P and Q.

These circles evidently cut one another orthogonally in R; for BR, which is a radius of the one, is a tangent to the other.

Thus particles moving in a plane, so that the speed at any point R is inversely as PR. RQ, may describe circles in which PQ is a chord. In this case the curves of equal action are circles defined by the condition that the ratio PR : RQ is constant. Or they may move in the latter system of circles, in which case the former system gives the lines of equal action. For the equations in the preceding section give

$$v^2=\left(\frac{dA}{dx}\right)^2+\left(\frac{dA}{dy}\right)^2=\left(\frac{dA'}{dx}\right)^2\left(\frac{dA'}{dy}\right)^2=\frac{4a^2}{r^2r_1^2};$$

from which the conclusion is obvious.

We may easily extend this example to other sets of orthogonal curves whose equations are

$$A_1=pA+A',$$
$$A_1'=-A+pA',$$

where A and A' have their recent values. Or we may extend the example by assuming at starting

$$A=m\log r-m_1\log r_1,$$

in which case it will be found that we must have

$$A'=m\theta-m_1\theta_1.$$

These pairs may again be combined into

$$pA+A' \text{ and } -A+pA', \text{ and so on.}$$

It will be noticed that in these examples the curves of equal action and the paths of the particles correspond in steady fluid motion to curves of equal pressure and lines of flow, and in electric conduction to equipotential lines and current lines. In such cases in fact, where there is no vortex-motion, the action is closely analogous to what is called the "velocity potential" in a fluid. Analogy between action and velocity potential.

*Generalized Coordinates.*

§ 215. By the help of the result already obtained in connexion with least action, we may easily obtain in a simple, though indirect, way the remarkable transformation of the equations of motion of a system which was first given by Lagrange. We are not prepared to give here the transformation to *Generalized Coordinates* in its most general form; but, even in the restricted form to which we proceed, it is almost invaluable in the treatment of the motion of conservative systems of particles in which the number of degrees of freedom is less than three times that of the particles. The one point to be noticed is that, when we restrict ourselves to a system of this kind, the expression for the kinetic energy, T, is necessarily a pure quadratic function of the rates of increase of the generalized coordinates. This is obvious from § 19. Repeating with generalized coordinates the investigation of § 202, we have Generalized coordinates.

$$A=2\int T\,dt=\int(T+H-V)\,dt.$$

Hence
$$\delta A=\int(\delta T+\delta H-\delta V)\,dt.$$

Now let $\theta$, $\phi$, $\psi$, &c., be the generalized coordinates, and we have

$$2T=P\dot\theta^2+2Q\dot\theta\dot\phi+R\dot\phi^2+\ldots\ldots\ldots$$

where P, Q, R, . . . are in general functions of $\theta$, $\phi$, $\psi$, . . . Of course V is a function of $\theta$, $\phi$, $\psi$ . . . alone, and does not involve $\dot\theta$, $\dot\phi$, $\dot\psi$, &c.

Thus we have, writing for one only of the generalized coordinates,

$$\delta A=\Sigma\int\left(\left(\frac{dT}{d\dot\theta}\right)\delta\dot\phi+\left(\frac{dT}{d\theta}\right)\delta\theta-\left(\frac{dV}{d\theta}\right)\delta\theta\right)dt+t\delta H$$

$$=\Sigma\left(\frac{dT}{d\dot\theta}\delta\theta\right)+t\delta H-\int dt\,\Sigma\left[\left(\frac{d}{dt}\left(\frac{dT}{d\dot\theta}\right)-\frac{dT}{d\theta}+\frac{dV}{d\theta}\right)\delta\theta\right]$$
